It is impossible to convey an idea of the amount of painstaking labour that has been spent on this atlas, the wonder rather is how it was all done. So far as we can judge, the very elaborate fulness of the matter, with the admitted imperfections of the methods used, will cause the work to appeal to the specialist in leucocyte work rather than to the practitioner, although the plates show leucocytes from all forms of diseased conditions. Even the specialist may find the text too drawn out. Be that as it may, the author is tremendously in earnest and has elaborated his theme with true German thoroughness. We shall be glad to welcome the supplementary part, in which we hope the author will give a *résumé* of the main advances and present bearing of a subject of great complexity but of much practical importance to the morphologist, physiologist, and practitioner.

LIBRARY TABLE.

Science, Matter, and Immortality. By RONALD CAMPBELL MACFIE, M.A., M.B., C.M. London: Williams and Norgate. 1909. Pp. 300. Price 5*s.* net.—This book is a popularly written and somewhat flamboyant account of modern and ancient views upon atoms, electrons, the ether, cosmogonies, nebulæ, and kindred subjects. There is but little about immortality in the work, that is to say, considering immortality in its theological sense, although in his closing paragraph Dr. Macfie utters the truism that, "Conceived aright, science must always lead to belief in the unseen and to hope of immortality ....." The chapter upon Lucretius is one of the best in the book and Dr. Macfie ends it with a striking aphorism. After mentioning that "it is as necessary for culture to understand ancient views of matter as ancient views of God," he continues: "The sun of Truth can be rightly viewed only by means of the parallax obtained at the extremes of Time." In his chapter on Cosmogonies we think that Dr. Macfie scarcely gives Kant enough credit for his share in the nebular hypothesis, for Kant certainly evolved this theory prior to Laplace. But a study of Dr. Macfie's book may lead those desirous of knowing more about modern theories of matter and energy to study the subject in more extended treatises, and in this way it is useful.

Pulmonary Tuberculosis and Sanatorium Treatment. By D. J. A. CHOWRY MUTHU, M.D. Brux., Physician, Mendip Hills Sanatorium, Wells, Somerset. London: Baillière, Tindall, and Cox. 1910. Pp. 201. Price 3*s.* 6*d.*—The object of the author in writing this work is to give a brief survey of "the scientific, the sanatorium, and the social aspect of tuberculosis," and while he expresses views which will not meet with general acceptance, his book is an interesting one and the practical details are sound and instructive. His main theme is the importance of trusting Nature. Dr. Muthu suggests that long ages of civilisation and hereditary influence have not only created conditions for the preparation of the human soil, but that in this altered atmosphere the nature of the seed, the micro-organism, has also changed its character. Elaborating this argument, he states the opinion that micro-organisms begin their life as saprophytes and help in various natural processes of life, "but vicious environment changes their character, so that they take on new properties and become pathogenic." Dr. Muthu then discusses the conditions under which he believes the virulent properties are acquired. He maintains that this change is brought about by alterations in their environment which affect their constitutional properties; further, he says, this altered environment is greatly the outcome of the conditions of civilisation and may be provoked by many factors. The circumstances he mentions are: (*a*) a lowered vitality caused by a wound, previous disease, overcrowding, physical and mental strain, and other evils of modern town life; (*b*) increased nutrition, rich living, undue consumption of nitrogenous matter; (*c*) foul air, charged with organic impurities, and other insanitary conditions; and (*d*) frequent contact with people in towns and cities and ill-ventilated buildings. Whilst admitting that these conditions are conducive to ill-health and the spread of disease, we are not prepared to allow that they can transform harmless germs into tubercle bacilli. The discussion on the principles of the open-air treatment is well written, and the details of the life in a sanatorium are described in terms which are easy to understand and appreciate. The social and economic questions in connexion with tuberculosis are considered in moderate terms and no extreme views are adopted. We were much interested in reading this work, although, as we have said, it contains certain opinions with which we are not in sympathy.

Sleep and Sleeplessness. By HAYDN BROWN. London: Hutchinson and Co. 1910. Pp. 160. Price 2*s.* 6*d.* net.—This work belongs to a class which, as a rule, in our opinion is perilous—namely, a book on a medical subject written for non-medical readers. However, insomnia is very common, and many persons drug themselves, so Mr. Haydn Brown's remarks about the evils of drug-taking have some justification. These chapters and the final one of the work are the best parts of the book. We are glad to see that Mr. Brown lays stress on the necessity of sleepless patients, or those suffering from neurasthenia, consulting a medical man, for persons of this type are just those who fly to quacks. But, as a whole, the book exhibits the fault which nearly every book of its class does exhibit: there is too much medicine for the layman and nothing new scientifically for the trained reader, if such a one should read it. We do not think Mr. Brown correct in calling an astronomical telescope "a very big powerful microscope," though the optical principles of the one are much the same as of the other. In the chapter on simple inducements to sleep, one which is both potent and in many cases easily obtainable is not mentioned—namely, a run of 50 miles or so in a motor-car.

Neighbours and Friends. By M. LOANE. London: Edward Arnold. 1910. Pp. 322. Price 6*s.*—This is another of Miss Loane's admirably written and sympathetic books about the poor. Miss Loane, in her capacity as a Queen's nurse, has every opportunity of witnessing the inner life of the poor and of seeing them at their best and at their worst. Anyone who works successfully among the poor must be possessed of an optimistic temperament and, above all, of

a sense of humour; and Miss Loane evidently has both. For instance: "A few days ago a repulsively dirty matron clasped me warmly by the hand, exclaiming, 'You're a lady like meself, though I'm a bit in my dishabeels.' Just before this a slight misunderstanding had driven her to the extreme course of calling me a woman. The misunderstanding had not been cleared up; it had simply been blown to the futhermost limbo by the chance discovery that I had given myself the trouble to be born in the same parish, and at about the same date as she had been married to her first husband." A chapter dealing with nurses and entitled "Vocation," we can thoroughly recommend to any young woman who is thinking of becoming a nurse to read and ponder over. Miss Loane deserves thanks for a most instructive and amusing book.

JOURNALS AND MAGAZINES.

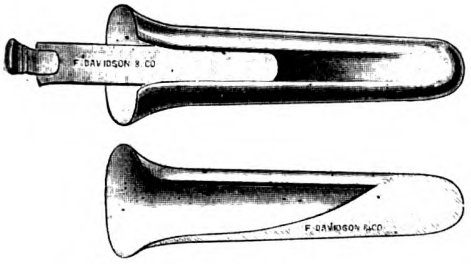
The Fifteenth Bulletin of the Sleeping Sickness Bureau.—This number of the *Bulletin* keeps well up to the high standard of its predecessors. It contains an abstract of an important paper which was read at a recent meeting of the Royal Society by Professor E. A. Minchin and Dr. J. D. Thomson on the Transmission of Trypanosomes, dealing more particularly with the transmission of T. lewisi by the rat flea. The experiments were made with fleas which had been bred in flea-proof cages in the laboratory. The conclusions derived from the investigations were that the rat flea can transmit the T. lewisi from infected to healthy rats, and that this transmission takes place by a cyclical method and not by direct transference. The developmental cycle period in the flea has a minimum of six or seven days but may be longer; the multiplication period of the trypanosomes in the rat is about 12 days. In the developmental cycle the establishment of the trypanosomes in the flea begins with multiplication of crithidia-like forms in the rectum. Among other papers in the *Bulletin* may be mentioned those relating to the leucocyte formula in trypanosomiasis, the influence of other infections on this disease, the treatment of trypanosome infections, trypanosomes with "blepharoplasts," trypanosoma vivax, life-histories of trypanosomes in vertebrate blood, &c. The number also contains the latest sleeping sickness news, and the monthly list of references is continued. We have also received from the Sleeping Sickness Bureau the "Subject-Index to the Bibliography of Trypanosomiasis," compiled and arranged by Mr. C. A. Thimm, the librarian of the Bureau, with additional references and corrections. This subject-index will prove invaluable to all those who are engaged in work connected with trypanosomiasis.

The Medical Chronicle.—In the April issue Dr. R. W. Marsden and Mr. C. Powell White describe a peculiar tumour of the palate which seemed to belong to the class called cylindromas, and Mr. Garnett Wright discusses gallstones from a clinical aspect, dividing them into cases accompanying chronic, acute, and suppurative cholecystitis and cases characterised by jaundice. Dr. C. Paget Lapage publishes a contribution to the study of infantile mortality, analysing the causes of this condition; and Dr. R. T. Williamson reviews recent literature on the subject of acute anterior poliomyelitis, which has been experimentally transmitted from man to monkeys and from animal to animal.

Edinburgh Medical Journal.—A further study of the bacteriology of suppuration in the accessory sinuses of the nose, by Dr. A. Logan Turner and Dr. C. J. Lewis, appears in the April issue of this magazine. The authors conclude, among other things, that of the many bacteria which may be responsible for such affections pyogenic cocci are the commonest; that nasal infection of the antrum is more common than dental; and that while recent cases of suppuration in this cavity are readily cured by lavage, prognosis is doubtful in chronic cases, a large number of lymphocytes in the discharge being of evil omen. Dr. H. M. W. Gray writes on the diagnosis and surgical treatment of cancer of the stomach, Dr. George L. Chiene gives notes of a case of traumatic subcoracoid dislocation of both shoulders, Dr. James W. Keay describes some details of technique in perineorrhaphy, and Mr. J. M. Cotterill records examples of snapping hip and snapping finger.

The Bristol Medico-Chirurgical Journal.—The March number opens with a very interesting paper by Dr. James Mackenzie Davidson on radium, in which is given an account, not only of the peculiar properties of this substance, but also of the conditions in which it is useful therapeutically. Among these are some diseases of the eye, and also, curiously enough, forms of dermatitis caused by X rays. Dr. Carey Coombs writes on diffuse destructive changes in the liver associated with jaundice—the group of conditions which is usually called acute yellow atrophy of the organ, but which, as he points out, shows changes other than atrophy and need not run a very acute course. Mr. Hugh P. Costobadie contributes a short paper on hypnotism, and illustrates the light that may be thrown on psychological problems by a study of hypnotic phenomena; and Lieutenant V. B. Green-Armytage, I.M.S., records some curious oriental medical customs seen in India and Burma.

The Birmingham Medical Review.—The March issue of this magazine contains two papers of considerable interest from the point of view of heredity. In the first Mr. Priestley Smith discusses this principle in relation to national welfare, showing the truth of the Mendelian laws as applied to the human species, emphasising the degeneration which seems to be affecting our own country. In the second Dr. James E. H. Sawyer describes a case of Huntington's chorea, and gives a table showing the incidence of the disease in two generations. The patient actually seen by him was a man, aged 38 years, who had suffered from the trouble for two years but seemed quite unconscious of his malady, possibly owing to the degree of mental defect which it had produced.



West London Medical Journal.—In the April number is published a paper by Mr. Donald J. Armour on the treatment of tumours of the brain; the writer takes a hopeful view of the value of surgical measures both for the cure and the relief of such conditions; indeed, he seems hardly to admit that there are any cases in which such treatment cannot do good. Dr. T. Grainger Stewart writes on affections of the brain due to vascular disturbance; and Dr. Julius M. Bernstein discusses infective endocarditis and analyses 20 fatal cases in which bacteriological examinations were made and showed the presence of several different germs. Dr. Seymour Taylor contributes a brief note on examination of the urine, emphasising the value of picric acid as a test both for albumin and for sugar.

THE EMPEROR OF JAPAN AND THE SEAMEN'S HOSPITAL.—On April 13th the Japanese Ambassador unveiled a bronze tablet which has been placed over a bed endowed by the Emperor of Japan at the Seamen's Hospital, Greenwich. In performing the ceremony the Ambassador said that this was the first opportunity that had presented itself to him for intimating the indebtedness of the Japanese nation to the hospital for the care and attention which were bestowed on Japanese seamen who were admitted to the wards of the hospital. The tablet is oval in shape and bears in the centre the inscription, "The Chrysanthemum Bed, 1908," surmounted by the Japanese emblem of the rising sun, with chrysanthemums on either side.

New Inventions.

IMPROVED RECTAL SPECULUM.

FOR rectal examination, combined with the injection treatment of hæmorrhoids as practised by Dr. Eugene Hoyl of New York, the speculum ordinarily used in this country is Hilton's with Bryant's modification. In withdrawing this speculum, however, the piles tend to catch on the more or less sharp edges, causing much pain to sensitive patients. Messrs. F. Davidson and Co., of 29, Great Portland-street, London, W., have at my suggestion manufactured a speculum

by which this difficulty is overcome. As shown in the accompanying illustration, the improved speculum is cone-shaped, with a sliding piece which on partial withdrawal causes the piles in the exposed area to appear. The slope in the wall of the speculum is very gradual, with smooth and rounded edges. The sharp and more or less cutting edges peculiar to the old form are avoided, so that the withdrawal of the instrument is quite easy and painless.

Seymour-street, W. JAMES SEARSON, M.D. Brux.

A NEW SYRINGE FOR DELIVERING ACCURATE VOLUMES OF TUBERCULINS OR VACCINES.

THIS syringe has been designed to provide a means by which glass "ampoules" may be rapidly and accurately filled with definite quantities of fluid. The amount of fluid ejected from the syringe into each "ampoule" is regulated by means of bosses in conjunction with a screw disc stop, the latter regulating the descent of the plunger to the height of the particular bosses employed (0·5 cubic centimetre and 1 cubic centimetre bosses are usually supplied with the syringe). The thread on the piston-rod is of a rapid type, upon which the disc stop travels quickly on receiving a slight impulse from the finger. The syringe is so constructed that every part may be sterilised by boiling, and the plunger, which is of asbestos, will absorb sufficient moisture during the process to act as an efficient lubricant. These syringes have also been made with metal plungers, but the asbestos plungers have proved to be more easy and less costly to maintain. Messrs. Down Bros. owe the suggestion to produce such syringes to Dr. J. W. H. Eyre, who has employed them for some considerable time in the Bacteriological Department of Guy's hospital, where they have given every satisfaction.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 21st, 1832.

DISINFECTION BY HEAT.

LETTER FROM DR. HENRY IN REPLY TO THE STATEMENTS OF MR. WALLACE.

To the Editor of THE LANCET.

SIR,—Having long ceased to be a reader of periodical works on medicine, the letter of Mr. Wallace,[1] in the 446th number of your Journal, might have entirely escaped my notice, had it not been sent to me a few days ago by a friend.

Until I read that letter, I was totally ignorant that any person but myself had ever directed his attention to the disinfecting powers of high temperatures. This distinct and unqualified declaration will at once satisfy all who know me. To those who do not I offer the following explanation.

The occasion which first induced me to undertake an inquiry into the disinfecting powers of heat arose in the summer of 1824, out of a pressing emergency. Cargoes of raw Egyptian cotton, of the value of upwards of twenty thousand pounds, had been long detained under quarantine at Milford Haven, to the great injury of the owners; by whom I was earnestly requested to suggest some method of shortening the time of expurgation. A few days only were allowed me for considering the subject, and performing the experiments, the results of which led me to propose the application to the raw material of a *dry heat*, obtained, for security to the goods, by means of steam. This proposal was immediately communicated to the owners; but the early liberation of the cargoes rendered its adoption unnecessary. It was, at a subsequent period, laid before the late Right Hon. Mr. Huskisson,[2] by a most respectable deputation of Liverpool merchants; and every facility for trying it was promised by that gentleman, if any similar exigency should in future arise.

After the lapse of seven years, I was induced, last August, to resume and extend the inquiry, by the threatened approach of Asiatic cholera to our shores. Led by a train of reasoning on the corpuscular arrangement of the elements of animal compounds, I made the experiments on the destructibility of the contagions of cow-pox, typhus, and scarlatina, which are related in the Philosophical Magazine for January last. That I might not, however, incur the risk of trespassing on ground already, without my knowledge, occupied by any one else, I inquired of several professional friends, whether their reading furnished any instance of similar views. Among others, I consulted Dr. Traill (president of the Philosophical Society, and physician to the Infirmary at Liverpool), as one distinguished not only by his extensive acquisitions in science, but in medical literature. After carefully searching the volumes most likely to afford such information, he expressed his belief that my views and experiments were entirely original. This, too, is the uniform tenour of the opinions (now in my possession) of other physicians of acknowledged learning.

My earliest views respecting disinfection (it must be kept in mind) were entertained by, and the proposal arising out of them suggested to, the owners of the cotton, in August 824. Early in 1825, Mr. Wallace, it appears, published a tract entitled, "An Account of the Apparatuses for the Treatment of Rheumatism, and Diseases of the Skin which have been constructed at the Dublin Skin Infirmary." A copy of this, it seems, was sent by the author to the library of the Manchester Infirmary, in February 1825. But having retired many years before that period from the office of physician to that institution, and having long relinquished medical practice and medical studies, I never heard of Mr. Wallace's book, or of its contents, till I read his letter a few days ago. Having now examined the copy alluded to, I find that the whole of what it contains respecting disinfection by heat, is the paragraph of fourteen lines copied into THE LANCET (p. 855); but that not a single line is to be found in it respecting the experiments on the destructibility by heat of the poisons of cow-pox, small-pox, and syphilis, to which Mr. Wallace lays claim at p. 856. To any other source of information respecting his views I never had, nor could have had, access. He cannot expect that I should be acquainted with what he may have taught in lectures, or communicated through channels not open to the public at large.

Yet, on these slender grounds has Mr. Wallace, an entire stranger to me, founded an insinuation, too plain to be misunderstood by any one, that I have appropriated to myself information taken without acknowledgment from him. His right to claim whatever he may think belongs to him I do not dispute; but he is not justifiable in imputing to me an offence, degrading (if there were the slightest foundation for the charge) alike to my moral and scientific character, and in doing so, he has himself offended against the rules of candour and of justice.

I am, Sir,

Your obedient servant,

WILLIAM HENRY.

Manchester, April 5, 1832.

1 *Vide* "Looking Back" in THE LANCET of March 19th, 1910, p. 817.

2 Mr. William Huskisson, President of the Board of Trade, died as the result of being run over by a locomotive at the opening of the Liverpool and Manchester Railway in 1830, just after being greeted by the Duke of Wellington. In his early days he was intended for a medical career.

THE LANCET.

LONDON: SATURDAY, APRIL 23, 1910.

Antisepsis and Asepsis in Midwifery Practice.

THE efficient safeguarding of the mother during childbirth from the danger of septic infection is a problem which presents many difficulties from the practical point of view. If we accept the teaching that all cases of puerperal septicæmia are due to the introduction of pathogenic organisms or their toxins into the patient's body from without, then in uncomplicated cases of labour the danger can be averted to a large extent by the avoidance, as far as possible, of any manipulation, such as a vaginal examination, which might result in the contamination of the patient. While this is usually easy in a normal case it is impossible in any case of difficulty, and at least one vaginal examination must be made, as a rule, in every case of labour, even of the most uncomplicated and straightforward type. Since the conduct of a case of labour without any vaginal examinations requires a greater degree of training and practice in abdominal palpation than fall to the lot of many students and most nurses, we must of necessity take care that internal examinations, which must be made, shall be as little dangerous as is consistent with the exigencies of private practice. How this end is to be attained best is a problem which teachers are by no means unanimous in answering. In a letter to the Master of the Rotunda Hospital, Dublin,[1] a correspondent puts the very pertinent question as to what procedure the former would recommend with a view of preventing most certainly the occurrence of any septic trouble if called upon single-handed to deliver a patient of a fœtus or placenta and at the same time to keep the patient fully anæsthetised. He also asks for some suggestion as to keeping forceps sterile after they have been boiled when they are not required for immediate use.

It is obvious, in attempting to give a practical answer to such a query that we must first decide very clearly whether we intend to practise asepsis or antisepsis. Is the aseptic treatment of a case of labour in private practice possible, or even desirable, and if it is, does it in these circumstances present any advantages over the antiseptic method of treatment? It appears to us that no profitable discussion of this question can be carried on unless to start with a clear distinction is made between these two methods of treatment. In our opinion, perfect asepsis is more difficult to maintain than perfect antisepsis, and the former method is more likely to break down in unfavourable surroundings, while if any failure takes place the consequences are more likely to be serious. When we consider the large amount of care and the elaborate precautions which are required for the successful practice of aseptic surgery, and when we contrast the surroundings of the modern operating-room with those met with in most cases of midwifery in private practice, it is obvious that there can be no real analogy between the two. Further than this, if we were asked which required the greater degree of surgical training and the highest development of the so-called surgical conscience, we would at once answer the practice of aseptic surgery. For these reasons in attempting to answer the questions put to the Master of the Rotunda we would regard the maintenance of strict aseptic precautions in ordinary midwifery practice as a matter of considerable difficulty, in which view we believe we should have the concurrence of the great majority of the teachers of midwifery in this country. Asepsis is superior to antisepsis if it can be maintained, but in the present circumstances we are concerned not with surgical operations carried out under the best conditions but with operative midwifery carried out only too often under very bad conditions. Dr. E. HASTINGS TWEEDY in his answer to his correspondent describes a most ingenious method of conducting a labour, with the least possible danger to the mother of septic infection, in the circumstances indicated, which, however, depends for its success upon the practice of strict asepsis. He relies upon the use of sterile rubber gloves and of sterilised instruments if we understand him rightly, and apparently lays but little stress upon the employment of antiseptic lotions either for the hands, the gloves, or the instruments used. Rubber gloves in the conduct of labour cases are very useful, always provided that sufficient care is taken to render the hands as sterile as possible, that the rubber gloves themselves are protected by the use during the confinement of antiseptic lotions, and that the further precaution is taken, which is insisted upon in most lying-in hospitals, of never touching the patient except with hands wet with an efficient antiseptic lotion, even if covered with rubber gloves. It is, however, a debateable question whether midwives should use rubber gloves or not; they are even at the present day costly articles, they rapidly deteriorate, require careful cleansing and sterilisation, and a careless nurse or midwife is not likely to take any more care of her rubber gloves than she does of her hands. They are especially liable to be torn in midwifery practice if instruments are employed, and if used as part of an aseptic technique require a greater amount of care to prevent them from contamination than is the case if they are worn in conjunction with the use of efficient antiseptics. Dr. TWEEDY considers that a benefit to humanity would be conferred if the Central Midwives Board compelled the universal adoption of rubber gloves among midwives. If there was any means of ensuring that such gloves would only be worn when intact and after a careful preparation of the hands by washing and the proper use of antiseptics, then certainly we would agree with this suggestion, but when we see how the habitual use of rubber gloves only too often produces a certain degree of carelessness in the proper cleansing and disinfection of the hands on the part of dressers and even of some surgeons, we shudder to think of the condition of the ordinary midwife's hands if she thought that she could always safeguard her patient from

[1] THE LANCET, April 9th, p. 1026.

infection by the use of rubber gloves. We admire the very ingenious manner in which the Master of the Rotunda arranges for the carrying out of the various manipulations, first with one gloved hand and then with the other, during the course of a labour lasting perhaps for some hours, but at the same time we wish that he had laid greater stress upon the use of antiseptics, since we believe that in this way the safety of the patient still more certainly would be assured. The chief reason for substituting aseptic surgery for antiseptic surgery is the injury inflicted upon the living tissues by the use of strong antiseptics, but this reason is of little importance in the conduct of a case of labour where the lotions are applied mainly to intact skin or mucous membranes; and since it is easier for a person with but little training in unfavourable surroundings to carry out the practice of antisepsis rather than that of asepsis, we regard the practice of asepsis as more difficult than that of antisepsis and therefore less likely to be certainly accomplished in private midwifery practice. The protection of the patient in these cases should be assured by means of the most certain and the most simple measures, and by such means as are least likely to fail in the emergencies which may occur in this class of practice. The use, therefore, of measures which, when properly and intelligently applied, are of the greatest value, but which present special difficulties and dangers unless practised in this most thorough manner, appears to us to require safeguarding. This can be readily accomplished, not only by the wearing of rubber gloves, the most important safeguard of all, but further by the intelligent and conscientious use of antiseptic lotions and the observance of strict surgical cleanliness. In this respect alone would we wish to amend a little the advice given by the Master of the Rotunda Hospital. To surgeons accustomed to operating in hospitals, surrounded by all the highly organised technique of aseptic surgery, and assisted by workers all trained to the highest degree in the observance of the necessary details, it is often a little difficult to realise how easily such a system may break down in other surroundings. For our part, while we cordially agree with Dr. HASTINGS TWEEDY'S methods, we would like to render the likelihood of any failure on the part of the practitioner more remote by advocating the employment in all such circumstances of both asepsis and antisepsis. In this way he will doubly safeguard his methods from any risk of failure and his patient from the danger of infection. At a recent discussion on the treatment of labour in contracted pelves one of the speakers expressed the opinion that the use of rubber gloves was merely a passing fad and one not likely to survive. This is a view with which we cannot agree. When used intelligently, and with due regard to the surgical cleanliness of the hands, rubber gloves are undoubtedly a most valuable addition to the surgeon's outfit; it must be remembered, however, that their cleansing and preparation requires special care, and must be done with extreme conscientiousness if they are not to prove an actual danger to the patient. If the gloves are torn the gloved hand may be a more potent factor in the production of sepsis than if no glove at all is worn, and for this reason some of the strongest upholders of the principles of asepsis do not wear them. In operative midwifery, as we have said, they are extremely likely to be torn, and unless they fit well are a hindrance to the introduction of the hand into the genital passages.

Dr. HASTINGS TWEEDY has given further a long list of all the things to be done when a case of midwifery is undertaken single-handed. Now although it is true that there are many things to be attended to, yet there is ample time, fortunately, in most cases, in which to carry them out, provided that the attendant makes proper preparations beforehand, for the various emergencies which may occur. Just as in the preparation of the hands we must depend upon antisepsis as well as asepsis, so in the disinfection of the instruments used asepsis alone is not sufficient. After boiling, the safest plan is to immerse the instruments in some efficient antiseptic lotion such as lysol, and to use them direct from that. The chances of contamination in a midwifery case are many, and no other plan is so safe in all instances. For the easy administration of chloroform in these cases the use of a Junker's inhaler is found by many to be the most convenient, and the method is simpler and in some respects safer than the administration of chloroform on a mask. In such details, however, every practitioner will follow the routine recommended to him by his experience. The main point which we wish to make is that the first essential in every case is the conscientious and efficient use of a combination of asepsis and antisepsis, as far as possible, in all conditions, and above all the avoidance of meddlesome midwifery. As to the manner of carrying out the details of such treatment no doubt there is room for a legitimate difference of opinion, but so long as this principle is strictly adhered to we do not think a patient would run any undue risk of infection, even when a difficult case of labour had to be undertaken without any assistance.

The Surgery of the Lymphatics.

THE lymphatic system has been, as it were, the Cinderella of anatomy, and surgery has thought it of but small importance. The student in his dissection learns little of the lymphatic vessels and he pays no attention to lymphatic glands unless they happen to be enlarged. Yet many years ago much work had been done on this subject, and SAPPEY'S monumental treatise suffices to show how extensive has been our knowledge of the lymphatic system for many years. Up to a very recent date surgery has contented itself with excising enlarged lymphatic glands, especially when the cause of enlargement has been tuberculosis or malignant disease. A definite change of view is now to be seen. Our knowledge of many obscure points in the minute, and even in the gross, anatomy of the lymphatics has been increased, and Professor STARLING, in his work on the fluids of the body, has advanced our knowledge of lymphatic physiology. Much has also been done of recent years in the pathology and surgery of the lymphatics, and to this advance Mr. W. SAMPSON HANDLEY has contributed in no small degree; while his recent Hunterian lectures at the Royal College of Surgeons of England on the Surgery of the Lymphatic System will bring the whole subject forcibly before the medical profession.

Mr. HANDLEY dealt mainly with the subject of the surgical

treatment of the brawny arm which occurs in a certain percentage of cases of cancer of the breast. His first contribution to the subject went to prove that this intensely painful condition is caused, not by pressure on the axillary vein, as was generally believed, but by obstruction of the lymphatics. This was an important step, for until a correct knowledge of the pathology was attained treatment would probably be of little avail. To the operation which he devised he gave the somewhat uncouth name of lymphangioplasty. It consists in the introduction of silk threads longitudinally in the subcutaneous tissue of the affected limb, which were intended to serve as new lymphatic channels. Mr. HANDLEY, before he first employed the method, had convinced himself that silk might lie in the tissues unabsorbed for as long a period as ten years, and the examination of a piece of silk removed after a prolonged sojourn in the tissues showed that though superficially eroded the main substance of the material was intact, and that the interspaces between the ultimate fibrils of the silk had not been obstructed by wander cells or so far as could be seen by any clotting of the tissue fluids. When, therefore, two years ago Mr. HANDLEY was asked to amputate an arm which had become dropsical as a result of carcinoma of the breast, he suggested the burying in the subcutaneous tissue of the arm of strands of silk which should act as new lymph-channels. This operation he performed, and thus he succeeded in relieving the pain and the swelling during the remainder of the patient's life. This was a very distinct advance, for, though the operation is purely palliative and cannot prolong life or modify the downward course of the disease, it can relieve all the pain which is not due to pressure on the nerves. This relief from pain is generally complete within twenty-four hours of the operation, and soon there is a marked and rapid diminution in the tension of the tissues of the whole area drained by the silk threads, so that the arm is soft in place of being hard and brawny, being also much diminished in size. If the operation has not been deferred too long there is a return of power to the paralysed arm, and the general condition is improved, for no longer is the patient tormented by the constant pain and loss of sleep, so that sedatives and hypnotics are but little required. The technique of the operation is simple: it consists merely in passing the threads by means of long probes from incisions near the wrist; when the probe has carried the thread as far as it can the surgeon cuts down upon its end, and through this opening the probe is reintroduced, and the thread is carried still higher in the limb. The upper ends of the pieces of silk are left embedded in the subcutaneous tissue of the back, a little below the scapula. Four double threads are inserted, one on each margin of the limb, both in front and behind. The most essential point in the treatment is the maintenance of a perfect asepsis in the silk used, and this is not easy, for there is risk of contamination at each opening in the skin.

Lymphangioplasty has been employed by Mr. HANDLEY in 15 cases, and the results have necessarily varied according to the conditions present. The most satisfactory results are obtained where the malignant disease has been of long duration, no discoverable mass of carcinoma is present, and no ulceration exists. When masses of new growth are present it is difficult to decide how much of the pain is due to nerve pressure and how much to the œdema. The mere presence of a growth in the axilla or above the clavicle is no bar to the operation, but relief was obtained in only half these cases. Even the presence of ulceration does not negative lymphangioplasty, but it is necessary to clean the ulcers and to shut them off from the field of operation. Even when pleural effusion is present and the balance of life remaining is likely to be short, lymphangioplasty may prove of service by relief of pain. In one case the patient was almost moribund, with thoracic cancer and pleural effusion, and suppuration occurred along the line of silk. Death followed a week later, and it is doubtful if her life was at all shortened by the operation. Lymphangioplasty has also been employed with success by Mr. A. B. MITCHELL of Belfast in cases of lymphatic œdema of the eyelids following erysipelas. Mr. HANDLEY has also employed the operation devised by him in cases of elephantiasis, but without success, yet his attempt has not been wholly in vain, for he has obtained evidence pointing to the probability of a microbic infection being a contributory cause of the production of this condition, and a vaccine may prove useful if employed at an early stage.

Another portion of the lectures dealt with the operative treatment of ascites. The Talma Morison operation, though of immense value in some cases, often fails. Dr. ESSEX WYNTER suggested the drainage of the ascitic fluid into the tissues, and Mr. HANDLEY performed drainage through the femoral canal, and in some of the cases success followed, but there are many difficulties to be overcome yet, and it cannot be said that up to the present the best method of operating has been settled. In Mr. HANDLEY'S lectures there was much that was new, and though time is needed to test the value of his operations we can at least feel sure that he has made contributions to surgery which will prove of permanent value by advancing our knowledge and our power of dealing with the lymphatic system.

A National Dental Scheme.

A LARGE sum of money has been placed at the disposal of Mr. B. C. RAYNER, secretary of the British Dental Association, in order that that body may put upon a working basis a scheme of dental treatment which is to be national in its scope. We briefly announced the fact last week. Under this scheme those classes of the community who are able to pay certain fees for dental care, but who cannot afford the charges of private dentists, are to obtain assistance of good quality at a moderate rate; and the scheme would be an example of private philanthropy coming to the assistance of the State at the time when the need of the State has been very clearly revealed, if it could be made certain that the benefits could be confined to those whom it was designed to aid. The inspection of school children has shown that the dental conditions prevalent in this country are extremely bad. Those who have inspected the children at the State schools have reported in different parts of the country even 80 or 90 per cent. of the children as having decayed teeth; and

without taking these appalling instances into account we shall be quite safe in believing that systematic dental inspection has already shown that nearly half of the class which receives State education have a certain number of carious teeth. Some large plan of therapeutics was therefore indicated, but it remains to be seen if the scheme now under consideration will meet the case. We understand that the sum placed at the disposal of the British Dental Association amounts to £200,000, and that the donor believes that the establishment of dental clinics, at which small fees will be paid, in course of time would turn into a self-supporting affair, realising interest at 5 per cent. while discharging work of incalculable value to the country. Such is the amount of dental work to be done, and such is the economy that can be practised by doing it on a large scale, that we believe the forecast of a pecuniary profit to be a safe one, but what are the guarantees that care will be taken lest persons should obtain the advantages of the scheme who could very well afford to pay the fees of a private practitioner? The dental hospitals already treat a considerable number of patients whom they feel to be no proper recipients of charity, but here there is the enormously important educational side to be remembered. The hospitals might welcome the assistance to their work which is implied by the possibility of drafting to other establishments an appreciable part of their *clientèle*, for throughout the country they require their space to meet the increased activity of the public with regard to the care of the teeth. But the practising dentist will see a good deal in the scheme to make him very thoughtful. In fact, we think it quite likely that there will be difficulty in obtaining the necessary qualified staffs, for many dentists will feel, and rightly, that the institution of such clinics is a blow at professional life. The dentists will become the servants of an institution which is to be made to pay. To run a large organisation of dental clinics a large number of dental mechanics will be required, and many of these will eventually swell the army of dental quacks. And lastly, what is to prevent that section of the public which can pay full and proper fees to private practitioners from seeking the dental clinics? We hope that the British Dental Association will look at the proposal very carefully before they accept the money.

Annotations.

"Ne quid nimis."

RECENT BIRTH-RATE AND INFANT MORTALITY IN THE LARGEST ENGLISH TOWNS.

NINE years having elapsed since the last census in the United Kingdom, considerable doubt now exists as to the population figures that should be adopted as the indispensable basis for vital statistics, as there are good grounds for doubting the trustworthiness of the official assumption that the rate of increase of population that prevailed in the United Kingdom between 1891 and 1901 has since been maintained. Until the results of next year's census are available there is, however, practically no option but to accept the Registrar-General's estimates of population, based on this assumption, trusting that our national vital statistics are not seriously invalidated by the probable over-estimate of the present population. In the 76 largest English towns the annual birth-rate during the first quarter of this year was equal to 25·3 per 1000 of the estimated population, showing a further considerable decline from the rate that prevailed in these towns during the first quarters of 1908 and 1909, which was equal to 28·3 and 26·7 per 1000 respectively. The birth-rate last quarter showed a decline of nearly 10 per cent. from the mean rate in the first quarters of the three preceding years. The present birth-rate in these towns may, however, be slightly understated through an over-estimate of the population. The deaths of infants under one year of age in these 76 towns during the first three months of this year did not exceed 115 per 1000 registered births, against 128, the mean rate of infant mortality in these towns in the corresponding period of the three preceding years, 1907–8–9. Infant mortality during last quarter in these towns showed, therefore, a decline of 10·2 per cent. from the mean rate in the same period of the three preceding years. This continued decline of infant mortality in our large towns is distinctly satisfactory, and suggests the inquiry whether, in view of recent very general administrative action for promoting increased care of infant life, it can be attributed, for instance, to the early notification of births to sanitary authorities. It is a fact, however, that the recent decline of infant mortality has not kept pace with the decline in the rate of mortality at all ages. During the first quarter of this year the annual rate of mortality in the 76 towns from all causes and at all ages did not exceed 15·0 per 1000, and was no less than 18·9 per cent. below the mean rate in the same towns in the corresponding period of the three years 1907–8–9; whereas the decline of infant mortality, as we have seen, did not exceed 10·2 per cent. While it is impossible to question the value of administrative action for checking the undoubted waste of infant life, it is unfortunately a fact that infant mortality is still declining at a slower rate than the death-rate at all ages.

ALCOHOL AND ALPINISM.

ABSTINENCE from, or a most moderate use of, alcoholic liquors has within the last 20 years become a marked feature of nearly all classes of society, and in none more markedly than in that composed of persons devoted to hard muscular exercise. Dr. L. Schnyder of Berne recently published in vol. vi. of the *Archives de Psychologie* the results of an inquiry set on foot by him amongst mountaineers as to their use of alcohol. This report has now appeared in an authorised English translation[1] by E. G. Richards, and it is a document of much interest. In 1903 Dr. Schnyder addressed a series of questions to about 1200 members of Alpine clubs, both Swiss and foreign, and received 573 answers. Of the members answering the question as to the use of alcohol in daily life, 573 in all, 446 habitually took alcohol in some form and 54 were total abstainers. Between these two lots came 73 who only took alcoholic beverages very occasionally. When mountaineering 412 carried alcohol and 161 carried none. Nearly all those who carried alcohol added that it should only be used at the latest possible moment, and then only very moderately. Dr. Schnyder's sixth question was, "Summarise your general impressions as to the rôle of alcohol in mountain climbing. Do you prefer another substance to it?" To this question he received 578 answers, of which 254 were distinctly unfavourable, 224 rather favourable than unfavourable, and 100 distinctly favourable.

[1] Alcohol and Alpinism. By Dr. L. Schnyder, Berne. Authorised translation by E. G. Richards. London and Edinburgh: William Green and Sons. 1910. Pp. 83. Price 2s. net.

Almost all the trained mountaineers are unfavourable to the use of alcohol in any form or at any time on the mountain, one notable exception being Mr. W. B. Coolidge. But even he only says that a small quantity of wine is a better restorative than tea or coffee and that cognac is indispensable as a reserve in case of exhaustion. Mr. Coolidge is an accomplished mountaineer and not a medical man, but his experience agrees closely with that given by Mr. Clinton T. Dent, who rarely takes alcohol with him, but says that the chief value of alcohol lies in its stimulating power to the appetite. "Let the man who can eat without alcohol not use it! But in the case of one who has no desire for food alcohol can stimulate that desire; and, what is more important, improve the power of assimilation at the same time." This action of alcohol was noticed in particular, we remember, during the Ashanti war of 1874. It was then found that alcohol on the march, though it gave rise to temporary stimulation, yet produced greater fatigue after the stimulation had passed off. On reaching camp at night the older men found that a small ration of rum increased their appetite and made it possible for them to enjoy their food. Beef tea was found to be a better stimulant for marching than alcohol, while it was not followed by secondary depression. Dr. Schnyder comes to the conclusion that alcohol is harmful during the climb, that it may be used to enable the climber to overcome *the last* obstacle as a final stimulus, and that it is useful as an aid to appetite and digestion. He suggests as a substitute for alcohol some substance containing caffeine, and has devised the following powder: kola and cocoa of each 5 grammes; sugar, 10 grammes; to be taken in a little water.

JONNESCO'S METHOD OF SPINAL ANÆSTHESIA.

Professor Thomas Jonnesco has been visiting the principal European capitals and America to demonstrate his views. In reporting his demonstration in London [1] we stated that the results did not bear out all his claims, for in two out of the three cases the anæsthesia was far from satisfactory. However, it was thought possible that this was due to the fact that the stovaine was sterilised, which is contrary to Professor Jonnesco's directions. In the *Montreal Medical Journal* for February Dr. W. W. Chapman reports a demonstration given by Professor Jonnesco at the Mount Sinai Hospital, New York, which confirms our criticisms. The operating theatre, it seems, was crowded by the New York profession. Professor Jonnesco was accompanied by his own assistant, who carried an ordinary Pravaz exploring syringe with a needle about 4 inches long, and two sealed bottles of strychnine solution of different strengths, a tube of stovaine crystals, and mixing tube. In the first case a man, aged 25 years, had his right breast removed for chronic mastitis. The patient was placed in the sitting posture with the chin flexed on the sternum. Having sterilised the skin and prepared the solution, Professor Jonnesco plunged the needle between the first two dorsal vertebræ to a depth of 3 inches, but no cerebro-spinal fluid appeared, even after aspiration, only blood. The needle was withdrawn and introduced a second time. Aspiration again yielded only blood, but afterwards a drop of clear fluid appeared and the solution was injected. After ten minutes the incision was made. The patient bitterly complained of the pain and begged for ether. Encouraged by the surgeon he allowed the operation to be completed. He afterwards stated that he felt every cut but one. An operation for inguinal hernia was performed under satisfactory anæsthesia, but after the operation the face was pale and there was some sweating. In a case of operation for tuberculous cervical glands upper dorsal puncture was performed, but after three attempts the spinal canal could not be found and spinal anæsthesia was abandoned. In an operation for appendicitis the anæsthesia was satisfactory, but the patient almost at once began to complain of headache. It is noteworthy that Professor Jonnesco considered the anæsthesia in the first case satisfactory. This appears to show that his success may be partly due to the fact that his Roumanian patients are more stolid than those in English-speaking countries. His other claim for his method—perfect safety—also requires more support. In the *Indian Medical Gazette* for February the death is reported of a native, aged 41 years, who was anæsthetised for removal of a large elephantiasis of the scrotum. The patient seemed to be in good health otherwise, though he was very stout. Three cubic centimetres of distilled water containing 1 milligramme of strychnine hydrochloride and 1 decigramme of novocaine were injected between the last two dorsal vertebræ and anæsthesia was rapidly induced. During the operation the patient complained of difficulty of breathing, which was attributed to the weight of the tumour which was turned up on the abdomen. When the operation was almost completed and the pedicle about to be severed respiration stopped and all attempts at resuscitation failed. In performing artificial respiration it was noticed that the arms were rigid. This was thought to indicate that death was due to the action of the strychnine on the medulla. A death has also been reported from the General Hospital, Birmingham.

THE CENTENARY OF BENEDIKT STILLING'S BIRTH.

ON Feb. 22nd, 1810, Benedikt Stilling was born at Kirchhain, near Marburg, of Jewish parents. In memory of the centenary of his birth the *Münchener Medizinische Wochenschrift* of March 29th publishes a brief notice of his career, together with his portrait. According to Dr. L. Strauss of Biebrich, who contributes his memorial notice, the remarkable researches of this great worker, whom Kussmaul described as "the pioneer and Columbus of a new world," have not received sufficient recognition even in Germany, although his name survives in the sacral nucleus of Stilling of the spinal cord. He was educated in the Gymnasium at Marburg and graduated in the university of the same town, shortly afterwards being appointed provincial surgeon at Cassel. Here he appears to have obtained distinction as an operating surgeon and soon to have acquired an European reputation. In spite of the demands made upon him by a very large practice, he was assiduous in research, for, as he himself said, there glowed hot within him the desire for scientific knowledge. His best known work is that dealing with the structure of the brain and spinal cord, at which he worked for nearly 40 years. He was the first to prepare complete serial sections and to trace groups of fibres in the nervous system by this means. He also demonstrated the cranial nerve nuclei situated between the corpora quadrigemina and the medulla oblongata, and in particular he described the nuclei of the hypoglossal, the vagus, and the facial nerves, the motor nucleus of the fifth, the nuclei of the fourth and the third nerves, and the upper nucleus of the spinal accessory. He established by experiment the nature of the vaso-motor mechanism and its relation to the sympathetic system. He also showed that an active dilatation of the blood-vessels as well as an active contraction occurred. His observations on conduction in the spinal cord were for the most part confirmed by later observers. Great as were Stilling's contributions to scientific medicine he did not neglect the practical side. He was one of the early ovariotomists, performing his first operation of that kind in 1837. He

improved the technique by introducing a so-called extra-peritoneal method and by his manner of dealing with the pedicles, which Nélaton characterised as the greatest advance made in regard to ovariotomy. He was one of the first in Germany to crush vesical stones, and he introduced new methods and instruments for the treatment of strictures of the urethra. This record of work achieved is truly remarkable in a man without the facilities of a professorial chair or of a public hospital. Dr. Strauss concludes his article by hoping that it may serve to render the name of Stilling more familiar to medical practitioners of the present day. A record of pioneer work carried through under difficulties is always stimulating, and we may hope that Dr. Strauss's interesting note will be widely read and achieve the purpose for which it was written.

IDIOPATHIC DILATATION OF THE COLON, OR HIRSCHSPRUNG'S DISEASE.

SINCE Hirschsprung in 1886 described the condition of dilatation of the colon to which his name has been applied a very considerable literature has grown concerning it. This was collected in an interesting review of the subject by Dr. C. Löwenstein[1] of Zürich in 1907. Dr. Johannes Lorenz has described an interesting case in which surgical treatment proved successful and given a review of the general characters of the affection and of the results of different forms of treatment.[2] The patient was a young man, aged 18 years, who was healthy until the second year of life, after which he suffered from children's ailments and from digestive disturbances. From his third year onwards he was subject to constipation and his abdomen was frequently distended. At the age of 13 years a severe attack of paralytic atony or ileus developed and each year he suffered from obstinate obstruction, lasting eight days and followed by prolonged diarrhœa. In November of 1908 a similar attack occurred more severe than usual, and associated with recurring pain. The patient was admitted to hospital, and the dilatation of the sigmoid flexure was established by the use of bismuth and the Roentgen rays. On examination the liver dulness was found to be obliterated, the heart pushed upwards, and the lower margins of the lungs in front were difficult to localise. The abdomen was greatly distended, especially in the upper part. The percussion note over the whole abdomen was tympanitic. To relieve the symptoms a cæcal fistula was made, but severe colicky pains in the left side persisted. On Feb. 6th, 1909, Professor Trendelenburg performed a radical operation. An incision was made below the umbilicus, when the greatly distended sigmoid flexure presented. Its length was 65 centimetres and its diameter 13 centimetres, while its wall was half a centimetre in thickness. The whole loop was excised, the cut ends of the colon were closed, and a lateral anastomosis was effected. The patient left the hospital cured on May 26th. The characteristic clinical features of this condition are meteorism and obstinate constipation, and these may commence very early in life. It frequently happens that purgatives and enemata fail entirely to relieve the bowels; indeed, enormous quantities of the latter may be retained. When an action is obtained the fæces often consist of friable masses not very hard in consistence and associated with very large quantities of offensive flatus. Often in the course of a few weeks the patient, who has previously been in apparently good health with a normal appetite, becomes rapidly ill, anorexia develops, severe colicky pains occur, the pulse becomes small and rapid, and paralytic distension of the small intestine develops. The abdomen under such conditions will be found to be greatly distended, the coils of bowel are visible, and peristaltic waves can be seen passing along them. The thoracic viscera and the diaphragm are pushed upwards and breathing is much impeded. Sometimes the passage of an intestinal tube enables flatus and fæces to escape, and afterwards, by means of enemata and digital manipulation, the distended bowel may be evacuated. Death may occur from general cachexia and cardiac failure, from peritonitis after perforation of a stercoral ulcer, from paralytic obstruction, and occasionally from collapse after too rapid emptying of the distended bowel. Of 90 cases in which the anatomical condition was investigated in 85 the sigmoid flexure was involved. The transverse colon was involved next in frequency. The ascending colon was dilated in 30 of the cases, and in 12 the lower part of the ileum showed changes. The pathogenesis of the affection is as yet obscure; by most authors it is regarded as congenital or as the sequel of congenital defects in muscular tone and innervation. In regard to treatment the results of medical measures are described as merely palliative. Dr. Lorenz describes the results of operative treatment in 41 cases: as death in 18, negative result in 1, improvement in 6, cure in 16. The procedure he recommends is resection of the distended part of the large intestine. Anastomosis appears to give less satisfactory results, and colotomy can only be advised as a preparatory operation to excision. Plication of the colon has been employed in two cases, in both with good results. Dr. Arthur F. Hertz in his interesting book on "Constipation and Allied Intestinal Disorders" states that in early cases medical treatment can cure the condition, but when surgical treatment is necessary he advises colostomy, which is occasionally sufficient to effect a cure. When this fails he recommends anastomosis between the ileum and the rectum, and finally colectomy, if necessary.

[2] Inaugural Dissertation, Leipzig, 1909, abstracted in Allgemeine Medizinische Centralzeitung, March 12th, 1910.

THE STABILITY OF THE PHYSIOLOGICAL PROPERTIES OF COLIFORM ORGANISMS.

THIS question of the stability of the physiological properties of micro-organisms is of considerable importance and of wide interest. The failure of morphological and cultural characters to provide sufficient criteria for the certain differentiation of microbes led the bacteriologist to resort for this purpose to a study of their physiological properties, and especially of their capacity to produce fermentative changes in various sugars, alcohols, and glucosides. These chemical actions have been of special importance in the study of organisms of the colon group and of the streptococci. It is obviously, therefore, a matter of great importance to systematic bacteriology to determine whether these properties are stable, or whether they may be lost or acquired by an organism when the conditions of its environment are modified. The importance of the problem, however, extends much beyond questions of differentiation of micro-organisms and concerns intimately our knowledge of the life-history of microbes in the periods of saprophytic existence, which with the majority of pathogenic germs alternate with the parasitic periods; these latter are, as a rule, much the better known. It is from this point of view that Mr. Cecil Revis studies the question of "stability" in the colon group in an investigation of much interest carried out in the laboratories of Messrs. Welford and Sons. In a series of well-devised experiments he examined the effect of prolonged growth in various media which were designed to simulate probable conditions met with during life external to the body; in contaminated and uncontaminated soil; in media deprived of proteid; and in media where sugars of various kinds were the sole source of carbon. The investigation was a difficult one,

and we are inclined to agree with the views of Burri, who holds that it is necessary to work with cultures derived from single organisms if absolutely reliable results are to be obtained, though we recognise the great practical difficulties involved. The facts that the search for colon bacilli is usually made in certain limited materials, the isolation of the germ secured by the use of severely eliminating media, and its culture conducted on a few media and under limited and fixed conditions, make the stability of their properties appear greater than it really is, as the variants are crushed out. It is the existence of these conditions which makes the instability of less importance than it would otherwise be in differentiating members of the colon group, and, as Houston has shown, secures a reasonable permanence of type. At the same time it is recognised that the properties are not stable or that the chemical activities possessed by a microbe are not always exercised. Indol formation is very variable and may be artificially checked or encouraged; fermentative power may be acquired, as has been shown by Twort in relation to dulcitol, and though in the research here considered the results are regarded by the author as negative, yet great modifications in the rapidity and amount of fermentation and other alterations were produced, so that strains quite unrecognisable as colon bacilli were obtained.

TOWN PLANNING IN GREATER LONDON.

A CONFERENCE of local authorities to consider the question of town planning in Greater London will be held, under the auspices of the National Housing and Town Planning Council, at Caxton Hall, Westminster, London, on Friday, May 6th, at 10.30 A.M. Invitations to attend the conference are being sent to the London County Council and to 88 local authorities in the Home Counties possessing statutory town planning powers in the Greater London area. It is desired to impress upon the conference the great importance of the new powers granted under the Housing and Town Planning Act, 1909, and to secure harmonious action between all the authorities in regard to those features of town planning which affect the development and amenities of Greater London as a whole. Further particulars may be obtained from the secretary, Mr. Henry R. Aldridge, National Housing and Town Planning Council, 4, Tavistock-square, London, W.C. The questions involved under the inclusive heading of town planning are many of them of the greatest medical importance, as we have pointed out on several occasions, and we hope that the professional voice will make itself heard at this conference.

THE USE OF TUBERCULIN IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

IN another column we publish an article by Dr. H. Warren Crowe on a New Method of Treating Acute Phthisis by the Alternate Use of Human and Bovine Tuberculin. His paper may be divided into two parts, the first detailing his method of treatment, and the second certain theoretical considerations which require careful study and comparison with the results of other observers before they can be fully accepted. Dr. Crowe adopts the plan followed by other physicians in employing very small doses of tuberculin (1/100,000th milligramme). He expresses his opinion that in "active phthisis," with a rectal temperature ranging above 100° F., a further rise of temperature, commencing sooner or later, and lasting a longer or a shorter time, is the most usual result of the smallest efficient dose of tuberculin. This is, however, contrary to the opinions of several English and foreign observers, who maintain that tuberculin given in small doses has an antipyretic action. It would be difficult to distinguish the subsequent rise described by Dr. Crowe from the effect of the disease. The use of bovine tuberculin has been described from time to time, but Dr. Crowe states that a prolonged reaction resulting from the use of either human or bovine tuberculin can be cut short by a dose of the other provided that there has been developed some degree of hypersensitiveness to the form of tuberculin which excites the reaction. He then describes the method in detail, and offers three theoretical considerations: 1. "Auto-inoculations theoretically must have a greater curative action than therapeutic inoculations of tuberculin in the treatment of phthisis (whether acute or chronic)." This opens up a large field of conjecture, for auto-inoculation as a therapeutic measure has not yet had a sufficiently long trial to afford a definite answer to this proposition. 2. "Tuberculin treatment causes hyperæmia at the lesion." This is generally accepted. 3. Inoculation of tuberculin causes auto-inoculation. Dr. Crowe's remarks raise interesting questions which cannot be settled in the space devoted to the subject in his paper. His observations are suggestive, but we believe that the subject has already received attention on the Continent. The tuberculin treatment has been carried out in such different ways that time alone can settle the most advantageous manner in which it can be administered.

ACUTE ARTHRITIS OF DOUBTFUL ORIGIN.

MANY cases occur in which acute inflammation of a joint appears without any obvious cause and without any definite indications as to the exact nature of the condition present. Dr. G. Burnside Buchanan of Glasgow has contributed a paper to this issue of THE LANCET in which he has related a number of these cases and has detailed the course of the disease and the treatment which he adopted. In many cases such as these there is no little risk that a diagnosis of rheumatism may be made, and often the greatest care is required to ensure that this mistake is not committed. Acute epiphysitis is one of the commoner of the conditions leading to acute arthritis arising without obvious cause, and a timely diagnosis of the site of the lesion, followed by incision and drainage of the focus of disease, will often result in a rapid and complete healing. When it is possible to recognise early, and with certainty, whether an inflammation is rheumatic in origin or not, surgeons will be in a better position to deal satisfactorily with the obscure forms of arthritis ably discussed in Dr. Buchanan's paper.

ON PUERPERAL AMAUROSIS.

IN a recent number of the *Ophthalmoscope* (March, 1910) Mr. Sydney Stephenson and Dr. W. P. Herringham record two cases of temporary blindness without ophthalmoscopic signs, associated with albuminuria in primiparæ. In one case there was eclampsia, but not in the other. Such cases have commonly been reported as uræmic, but to this designation the writers offer potent objections. In an exhaustive and critical review of the literature of the subject, which is to be commended strongly to the notice both of obstetricians and ophthalmologists, cases of amaurosis or amblyopia reported as occurring in pregnancy, during labour, and post partum are described. Well-reasoned comments upon the material thus collected lead the writers to the following conclusions:—1. A form of amaurosis or amblyopia, not accompanied by ophthalmoscopic signs, or, at least, by none adequate to account for the condition, may supervene during pregnancy, parturition, or the puerperium. 2. Rarely it may assume the form of an hemianopic defect or of a central scotoma in the fields of vision, or still more rarely of night-blindness. (The writers use the term "hemeralopia" for night-blindness. Owing

to the diametrically opposite meanings which are attached by authors to the terms "hemeralopia" and "nyctalopia" it is much to be desired that all ambiguity should be avoided by employing "night-blindness" and "day-blindness" in their stead.) 3. The condition is often associated with such signs and symptoms of toxæmia as headache, œdema, eclampsia, and scanty urine containing albumin, casts, and blood. 4. It appears to form one of the rarer manifestations of toxæmia poisoning. 5. It is not proved to be dependent upon uræmia, although it has usually been confused with so-called "uræmic amaurosis." 6. As a rule, the visual defect is recovered from completely in a few hours or days.

THE SUPPLY OF MIDWIVES IN LONDON.

THE Midwives Act Committee of the London County Council on April 19th drew the attention of the Council to the Order in Council issued on March 14th last authorising the Central Midwives Board to enrol, without examination, any women entitled under Section 2 of the Act of 1902 to be certified, but who failed to make application, provided that no one is admitted to the roll in this manner after Sept. 30th next. (The section referred to makes it illegal for uncertified midwives to practise unless they are able to show that they have been in practice for at least a year prior to July 31st, 1902.) From evidence given before the Departmental Committee appointed to consider the working of the Act of 1902 it appeared probable (said the committee) that the number of midwives at present certified under the Act would be insufficient in a few districts. It was to meet this difficulty, apparently, that the Order in Council had been made. In London, however, so far as could be ascertained, the number of midwives was in excess of requirements, and for this reason the Council had discontinued for some time the award of scholarships in midwifery. In these circumstances it seemed very undesirable that any addition of insufficiently trained persons should be made to the ranks of women permitted by law to engage in practice in London, and the committee recommended that the Central Midwives Board should be asked to refrain from admitting to the roll of midwives in London any person unqualified by examination. The recommendation was agreed to.

PAROTITIS COMPLICATING ACUTE RHEUMATISM.

INFLAMMATION of the parotid gland is well known to owe its origin in a majority of instances to an infective process. Even in the case of mumps, the precise etiology of which is as yet undiscovered, the general features are of such a kind as to leave little room for doubt as to the bacterial origin of the disorder; while those parotid inflammations which complicate pneumonia, peritonitis, enteric fever, and the process of rectal feeding, are traceable in each case to micro-organisms. The latest addition to the list of causes of parotitis is acute rheumatism, which is generally acknowledged to be an infective disorder, although there is disagreement as to the actual micro-organism concerned. M. Courtois-Suffit and M. Beaufumé [1] have brought together three cases of parotitis complicating acute rheumatism, two observed by themselves and one recorded by Gouget.[2] They have been unable to find other examples in the literature. These three cases are remarkably similar to each other. In each instance the attack was acute and affected many joints; the parotitis occurred either at or just after the period of maximum intensity of articular inflammation, and in all three cases it was the right parotid gland which suffered. With the appearance of swelling and discomfort in the parotid region a slight rise of temperature occurred; but in no case did suppuration occur, and in the worst of the three all evidence of parotitis had disappeared by the sixth day. The briefness of the inflammatory process and its complete disappearance under treatment with salicylate of soda suggest a directly rheumatic origin in the opinion of M. Courtois-Suffit and M. Beaufumé, thus contrasting with those types of parotitis already referred to, in which some micro-organism other than that responsible for the underlying disease is probably concerned.

[1] Gazette des Hôpitaux, March 8th, 1910.
[2] Ibid., Nov. 24th, 1904.

A NEW session of lectures and demonstrations at the Hospital for Sick Children, Great Ormond-street, will commence on Thursday, May 5th next, at 4 P.M., when Dr. F. J. Poynton will make "Some Observations upon Pericarditis." On May 12th Mr. Arbuthnot Lane will speak on the subject of Fractures. The lectures, which are free to all medical practitioners, will be continued each Thursday at the same hour, and the names of subsequent lecturers and the titles of their papers will be found in the diary columns of THE LANCET as the dates approach more nearly. Further particulars concerning the lectures and the clinical clerkships in the wards of the hospital may be obtained from the Dean, Dr. A. F. Voelcker, at the hospital.

Mr. Walter Runciman, President of the Board of Education, has appointed a Departmental Committee to consider and report upon the functions and constitution of the Royal College of Art and its relations to the Schools of Art in London and throughout the country. The committee is constituted as follows: Mr. E. K. Chambers, one of the principle assistant secretaries of the Board of Education (chairman); Sir Kenneth S. Anderson, K.C.M.G., Professor Frederick Brown, Mr. William Burton, M.A., F.C.S., Mr. Douglas Cockerell, Sir George J. Frampton, R.A., Sir Charles Holroyd, Hon. Litt.D., Mr. Halsey Ralph Ricardo, F.R.I.B.A., and Mr. Frank Warner; with Mr. A. H. Sidgwick, a junior examiner of the Board of Education, as secretary.

THE London and Counties Medical Protection Society, Limited, will hold its annual general meeting at 31, Craven-street, Strand, London, on Wednesday, April 27th, at 4 P.M. to receive and adopt the annual report and balance sheet, to elect the president, vice-presidents, council, officers, and auditors, and to transact other business.

THE annual general meeting of the Medical Defence Union will be held at the Royal Station Hotel, Hull, on Thursday, May 19th, at 5 P.M., when the annual report and audited balance-sheet of accounts will be presented and the statutory resolutions brought forward.

THE FACTORY AND WORKSHOP ACT.—A summary of reports on the administration of the Factory and Workshop Act, 1901, by local authorities during the year 1908 has just been issued in the form of a Parliamentary paper. Up to March 14th, 1910, out of 1847 reports due from England and Wales 1803 were received, while from Scotland of 325 reports due 317 were received. In Ireland 769 were due and 149 received. The Factory and Workshop Act requires medical officers of health to report annually to their local authorities, and it is explained that the number of reports outstanding from Ireland is probably due to the fact that only 20 superintendent medical officers of health are under obligation to make an annual report to the local authorities on the administration of the Public Health Acts. The recorded inspections of home-workers' premises are 93,443, as compared with 102,549 in 1907, and there were 1616 notices forbidding work in unwholesome premises, as against 1948 in 1907. The number of orders relating to infected premises was 640, as against 466. The fact that more reports are outstanding, as compared with 1907, may account for, in part, a decrease which appears in most of the statistics.

RABELAIS THE PHYSICIAN.

BY SIR HENRY MORRIS, BART., F.R.C.S., M.A. LOND.

THE interesting announcement under this heading which appeared in last week's issue of THE LANCET will be read with pleasure by everyone who finds enjoyment in good literature. The indelible renown of the author of "Pantagruel" and his giant father "Gargantua" rests on a much wider foundation than the fact that he was at once both a divine and a great physician—an association of two professions in the same person quite common at the epoch of Rabelais and for centuries before. Having received his first schooling in a Benedictine foundation, Rabelais became a novice, and took the vows of a novitiate in a Franciscan convent, which in turn he left to enter a Benedictine abbey and thus became a Benedictine monk instead of a Franciscan friar. He was guilty of apostacy from the rules of the Church by abandoning without the permission of his superior the garb of a monk for that of a secular priest, and travelling about the country from one university to another. He entered as a law student first at Bourges, next at Orleans, and afterwards as a medical student in Paris. He took his medical degrees in the University of Montpellier in 1530 and 1537. He gave anatomical demonstrations on the human body in the medical theatre at Montpellier (1537) and in the following year at Lyons. He invented surgical instruments for the reduction of fractures of the femur and for operating in cases of strangulated hernia. He was mentioned by Dolet as the "honour and sure glory of the healing art," and Salmon Macrin described him in a Latin ode as the most eminent physician, of whose skill "Paris, Narbonne, the banks of the Aude, and Lyons" were witnesses. He besought the Holy Father to grant him absolution from his apostacy, to allow him to hold any benefice that might canonically be conferred on him, and to practise the art of medicine "*in the way of Charity, without expectation of lucre or gain, and without the use of the cautery or knife.*" And the Pope granted all that his "beloved son" had requested. Then we hear of him at one time as a chaplain to a Bishop, at another time as travelling physician to a French Cardinal, at another as holding medical appointments at hospitals, and finally as a pluralist in Church preferment holding two livings, one at Meudon, near Paris, and that of Saint Christophe du Jambet, in the diocese of Le Mans. But above and beyond all this, Rabelais is principally famous because of his influence on the Renaissance, not in France only, but throughout the civilised world. Up to nearly the end, certainly till after the middle, of the fifteenth century, Greek was not understood in France. It was not until the arrival of a learned Greek, Janus Lascaris, in 1495 that the Greek language began to be studied in Paris. Soon after this a small coterie of Greek scholars was formed there, amongst the members of which were two physicians—viz., Guillaume Cop and Jean Ruel. Rabelais and a fellow monk, Pierre Amy, began to learn Greek about 1520, but under difficulties. If owing to prejudice and the scarcity of Greek texts the study was difficult in Paris, still more so was it in a Franciscan convent in a provincial town, where "*vows of ignorance*" as well as "*religious vows*" were required to be taken. But by getting into communication with several of the members of the circle of Greek scholars in Paris and with Erasmus the leading scholar in Europe, and by obtaining permission to exchange the Franciscan convent for a neighbouring Benedictine abbey, Rabelais found his difficulties diminished. A result of the revival of the study of Greek in Rabelais's case was that when lecturing at Montpellier in 1530 on the "Aphorisms" of Hippocrates, and the "Little Art" of Galen, he was able to base his lectures on a very ancient Greek manuscript of Hippocrates and on his own copy of Galen's complete works (now in the library of University College, Sheffield [1]), instead of on imperfect, mutilated, clericalised Latin translations, as other lecturers hitherto had done; and again in 1537, after he had been appointed one of the ordinary professors of the Faculty of Medicine, he used a Greek text for his lectures on the "Prognostics" of Hippocrates. Rabelais had broad-minded views on education. He propounded a scheme which aimed at stimulating the memory as well as the faculties of observation and reflection. It was practical as well as comprehensive. It embraced what to-day we call the modern or science and classical sides of our schools, and it included physical, and what is more hygienic, training as well. The student was never to be idle; rest ensues from change not from cessation of employment. Rabelais's relations to the Church were influenced by the teaching of his contemporaries, Luther and Calvin. He hated the monks and fell foul of the Sorbonne, yet he escaped the "*Chambre ardente*" of the Parliament of Paris, which was a criminal court specially erected for the trial of heretics. He favoured many of the doctrines and practices of Protestantism because they favoured principles of free inquiry and individualism, yet he rejected the French Protestantism as a creed. He never wrote anything against the principal doctrines and leading features of the Roman Catholic faith, and he celebrated mass and performed other offices in, and continued to be a member of, the Church of his forefathers. Moreover, Rabelais was deeply impressed with the great importance of the study of the Bible, whereas his illustrious countryman Montaigne, who lived a generation later, went a long way beyond him in his independence of, and opposition to, the Church, and regarded the teaching of the Holy Scriptures in the vernacular as not only not "helpful but dangerous." But Rabelais was a humanist first, and a theologian in the second place; he attached greater importance to national unity than to any particular creed or any form of ritual. He possessed an active imagination and a sceptical and an inquiring mind, but was consistent, not dogmatical, in regard to matters beyond the scope of actual experience and human knowledge. Without sacrificing sincerity or exercising hypocrisy he was guarded in his hostility to the Sorbonne. Though he sometimes used risky phrases in attacking the ignorance of the clergy and the prevalent evils of the Church and its ritual he sheltered himself behind "a privilege" which he obtained from the French kings, François I. and Henry II., for his books; or, agitated by the burning at the stake of some contemporary writer, he thought it advisable to leave France from time to time and sojourn at Rome or elsewhere as physician to Cardinal du Bellay until the first bitterness aroused by the jests and satires in his new books had had time to be forgotten or tolerated.

Undoubtedly the monument which it is proposed to erect in commemoration of Rabelais's connexion with the ancient and illustrious Faculty of Medicine of the University will find its appropriate place at Montpellier. But considering the universality and the greatness of his fame one is led to ask, with the writer of the article in THE LANCET which I have referred to, why a more ambitious project should not be undertaken. There is, or there was, if my memory does not deceive me, a statue of Rabelais near the bridge over the river Vienne at Chinon in Touraine. At Chinon, "the famous and noble Chinon, the first town in the world," with its ancient fortress, now in ruins, standing on a rock 300 feet above the river, Rabelais is said to have been born, and certainly his father had a house there. At Chinon Henry II. of England breathed his last in 1189, after crying shame upon himself as a beaten king. At Chinon in 1429 Jeanne d'Arc awakened in Charles VII. that spirit of enterprise and patriotism which led to his surname of L'Indolent being changed into that of Le Victorieux, and resulted in the expulsion of the armies of Henry VI. of England, who at his accession possessed nearly the whole of France, from territory after territory of that fair country till Calais alone remained to the English. With Chinon is associated also the name of the celebrated favourite Agnes Sorel, who exercised so great and beneficial an influence over Charles VII., and on account of whom and of the services of Jeanne d'Arc history has also given him the sobriquet of Le Bien Servi. But neither at Chinon his birthplace nor at Montpellier the University where he graduated, will a statue commemorate Rabelais so worthily as a fine monument in the metropolis of his native land would do. As the embodiment of the early French Renaissance, as the "Great Jester of France" as Bacon called him, as the greatest of French humourists and one of the greatest humourists of the world, and as the man "who has

[1] I am informed by Mr. Loveday, the librarian, that the Galen is the property of the Weekly Board of the Sheffield Royal Infirmary. It is the Aldine edition of the Greek published in Venice in 1525.

brought Aristophanes back to life and who imitates so well the satirical art of Lucian" as Joachim du Bellay said of him, Rabelais merits the grateful remembrance of the Frenchmen of to-day as much as he enjoyed popularity amongst and the love of those of his own time.

MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

The 15 h.p. Straker-Squire Car.

MOTOR-CARS are costly objects for medical men to invest in, and some of our readers do not seem to pay as much attention to the record of the firms with which they deal as they would with respect to, say, surgical instruments. The family history of a car is worth considering. Now everyone knows the name of Straker-Squire, for half the motor omnibuses bear that signature as a mark of their parentage, and motor omnibuses are nowadays tested severely and tried highly, so that the products of the firm which produces them must be able to stand a good deal of knocking about. This is a conclusion which a fairly long test of their one and only carriage model has confirmed in my mind. That they have specialised in the production of one model is to the advantage of the purchaser in the matter of quality and price, while it is another advantage that the car is English made, so that the owner can go to the place of manufacture and can see the component parts prior to their being put together, as well as watch sister cars being built and tested. It is true that nowadays a car may go, and probably will go, many thousand miles without an involuntary stop, still some mechanical tort may arise, so that it is as well to acquire by demonstration the anatomy and physiology of one's mount. With the 15 h.p. Straker-Squire car this is easily done, as the car is built throughout at Bristol. There are many opinions as to what constitutes a good doctor's car, but all admit, as being essential, sufficient power, smoothness and reliability, and quiet in running. A cheap car is dear if it constantly breaks down. With a view of ascertaining if the car in question possessed the necessary qualifications for medical needs I recently spent a day in driving one.

The chassis is fitted with four types of body—two-seater, four-seater, landaulette, and light runabout. I wanted to put the engine to as severe a test as possible, so as Messrs. Straker-Squire kindly left the choice to me I elected to carry out my trial run on the heaviest—that is, on the four-seater—with a Cape-cart hood and front glass, and in addition I loaded the car up with its full complement of passengers. Thus burdened the car did a short professional round in wet weather along the tram-lined narrow Woolwich road. It was on a Saturday, and Woolwich streets were thronged, so I had an ample opportunity to really test the brakes and control. Both answered perfectly to the slightest touch, and the way the car pulled up in traffic and started again, even on the top gear, was most satisfactory; while I may say that having all the brakes acting on the rear-wheel hubs answers just as well as the orthodox method of having one on the cardan shaft, and of course the former plan must save the transmission gear. Then we essayed a long run, and made for Sussex, over Shooter's Hill, which was done on the second speed easily, through Dickens's land, across country to Tonbridge, on to Battle, and then by rough lanes beside forests and on roads that showed what our car could do. Once we pulled badly, but the fault was mine, not the car's. We had stopped to admire a piece of scenery, and I dismantled the carburettor to find out its special features, in doing which I learnt that unknown carburettors need a little care in putting together, for in replacing the hollow spindle regulator, which controls the quantity of petrol, I neglected to adjust it at its former point, with the consequence that the mixture was too rich. So the car did not pull well, but as soon as the cause was diagnosed and the defect rectified the speed on the level was more than legal limit, and hills were easily negotiated, and mostly, even when they were bad ones, on the second gear.

The chief aim of the constructor of the car has been accessibility for inspection combined with simplicity. The engine has four cylinders cast in pairs, 87 mm. bore by 100 mm. stroke. The inlet and exhaust valves are on the same side and are operated from the cam shaft through the medium of a finger and extra light valve tappets, thus ensuring very quiet running. The cams are solid with the shaft, cut from the bar, and the design permits of the easy withdrawal of the cam shaft for inspection. The frame is of pressed steel, and the engine is hung directly on to it. An easily detachable steel undershield effectively protects the engine and transmission gear. The springs are semi-elliptic, and the shackles are provided with proper oilers, these being parts which usually escape lubrication. The water-pipes and cylinder passages are of generous dimensions, and the circulation, which is by thermo-syphon, is efficient. After a run of over 100 miles, which ended with a stiff hill climb, I found the engine cool, and I was able to hold my hand easily against the radiator. This latter is of the vertical gilled tube type, and a fan at the back, driven off the crank shaft, maintains the air circulation. The tension of the fan belt can be easily adjusted, as the fan spindle is eccentric and can be moved upwards or downwards by undoing a set screw. Ignition is by the now popular and satisfactory Bosch high-tension magneto, which is mounted in an accessible place in front of the engine and is driven by skew wheels off the two to one gear. The Bosch dual ignition can be had as an extra. Lubrication is by splash dippers at the end of the connecting-rods, picking up the correct amount of oil for the big ends and at the same time distributing it to the cylinder walls and gudgeon pins. The level in the crank case is maintained by a positively driven gear wheel pump; an indicator on the dash shows that the oil is circulating and when more should be added. The carburettor is fed by pressure from the exhaust. An auxiliary hand pump on the dash is fitted to permit of starting the supply to the float chamber. The carburettor is known as the "Ware," the feature of which is a simple contrivance whereby the amount of petrol passing to the jet can be varied. This method is simple and efficient, gives a correct mixture when properly set at all engine speeds, and acts without the use of any automatic spring or air valve, while from my experience during the day's journey I came to the conclusion that it was most economical. The clutch is of the old-fashioned, leather-faced cone type, and as springs are fitted under the leather the engagement is very gentle. The clutch and gear-box are connected by a double universal joint, and a good feature is that it can be dismantled without disturbing any other portion of the chassis. The gear box provides three speeds forward and a reverse, all operated by a single lever working in a quadrant, and the third speed is a direct drive from the engine to the differential. The transmission from the gear box to the back axle is by the usual cardan shaft and bevel gearing, the shaft being fitted with universal joints at either end. The live axle is designed so that the driving axle carries no portion of the weight of the vehicle. A particular feature is that the differential bevels can be removed without disconnecting the axle from the springs, and, in fact, without even the jacking-up of the road wheels; all that is necessary is to remove the hub caps, withdraw the driving shafts and dogs, take off the door at the back of the case, and then the bevels can be slipped out. The control consists of a hand control on the steering column, and the now universal foot accelerator pedal, coupled to the throttle on the carburettor, and there is no doubt that at times it is useful to have the two methods of regulating the throttle. The brakes, both the hand-controlled and foot, each act on drums integral with the road wheels. These are of the band type, are protected from mud and dust by an effective metal shield, and the back wheels can be removed without upsetting the adjustment of the brakes or removing the bands. They were separately tested on really steep hills and found to hold well and, what is more, to be soft and noiseless in action.

The foregoing description, I trust, shows that the Straker-Squire car has many interesting features, and should appeal to a large circle of motorists.

The Responsibility of "Back-fires."

In a recent case, in which the owners of a horse claimed compensation for damage done by an animal frightened by a back-fire of a car his honour Judge Lindley held that if a machine, from some cause or other, does make a noise calculated to frighten a horse of ordinary nerve, while the machine is on the highway, then the machine for the time

being is a "nuisance," and the owner is responsible for any damage thus caused. The moral naturally is to take care in starting that a back-fire does not occur in the exhaust, and in stopping to shut the throttle prior to switching off the ignition. Care should also be taken that the exhaust pipe joint is gas-tight and that the silencer is in a similar condition.

The Hooded Vehicle By-law.

A by-law which came into force in the counties of London, Middlesex, and Surrey at the end of the last month provides that the driver should have an unobstructed view through an arc of not less than 180°. Probably most owners of cars with Cape-cart hoods and side curtains have had mica or celluloid windows fitted in the curtain on the driving side of the car. Those who have not done so should have the same put in on account of the enforcement of this new and necessary by-law.

One of the Little Things that Count.

The other day I saw a motorist struggling with an old type of jack on the road and vainly attempting to lift a wheel with a punctured tyre with a tommy which was too small for the holes in the elevating part. It must have been bad for the temper to have to kneel in the mud; and then the tommy would slip out, and the jack thus not lift. These trying moments would have been avoided if a jack had been carried the top of which could be simply lifted to the height of the axle, the working handle being sufficiently long to permit of raising the car without having to bend down. Jacks of this type are made by Messrs. Tangye, Messrs. Lake and Elliot of Braintree, Essex, and Messrs. Lucas, and can be obtained of most dealers in motor sundries.

The Cost of Motoring Guaranteed.

The London Motor Garage Company, Limited, of 33–37, Wardour-street, W., to whose hire-purchase agreement I referred in the Motoring Notes of April 2nd, have drawn my attention to the fact that the prices which I mentioned included the cost of the car. The rates of the company for upkeep, maintenance, garage, including wages and board and lodging of competent driver, are £225 per annum for their 8-h.p. and 15-h.p. landaulettes. An allowance is made to such customers as provide stabling for their cars. Their terms include insurance against damage by accident or fire, theft of car or accessories, and unlimited third-party risks. The terms permit of a mileage of 6000 in the year, beyond which an excess of 4*d.* on the 8-h.p. car and 5*d.* on the 15-h.p. car is charged per mile. I take the opportunity of saying that I inspected their premises and found therein every convenience for garage, as well as repair of cars. As I mentioned in my previous notice, the company are prepared to enter into an agreement for hire and purchase, in which case the cost of the car is spread over three years, one-third being added to each year's maintenance charge.

POOR-LAW REFORM.

THE SCHEME PROPOSED BY THE RIGHT HONOURABLE CHARLES BOOTH: HIS VIEWS ON THE CARE OF THE SICK.

IN our recent leading article[1] on the debate in the House of Commons on Poor-law reform we referred to the proposal made by Mr. Charles Booth for the utilisation and adaptation of existing Poor-law areas, and of the present system of boards of guardians elected for that purpose, as an alternative for the schemes contained in the Majority and Minority Reports of the Royal Commission on the Poor-laws. His recommendations, in so far as they differ essentially from those of both sections of his brother Commissioners, are based upon the opinions: (1) That the administration of the relief of destitution should be in the hands of an *ad hoc* authority directly elected by the ratepayers; (2) that county and county borough areas are not large enough in many instances for the classification of the objects of relief and the provision of suitable special institutions under the desirable condition that these should have a constant supply of inmates numerous enough to enable economy to be combined with efficiency.

With regard to (1), Mr. Booth holds the view that the local authority has already enough to do, and he points out that the work of administering the Poor-law differs from that connected with sanitation, public health, police, and education in that these functions are carried out under powers of compulsory enforcement, whereas "the Poor-law, although it stands ready to assist, waits to be asked."

With regard to (2), he is in accord with Dr. Arthur Downes, who in his memorandum criticising the Majority Report[2] refers to Mr. Booth's opinions and dwells upon the insufficiency of many of the proposed areas. Mr. Booth objects also to the breaking up and rearrangement of areas of responsibility which would result from the adoption of the county borough as an administrative unit, as, for example, where now an urban union may conveniently include districts outside the boundary of a borough. We give below in outline the scheme of division of areas which he suggests, and also some observations which are of considerable interest upon the subject of the authority which should be responsible for the treatment of the sick under the Poor-law, particularly with reference to the proposal to transfer them to a health committee. His proposals, involving as they do no recourse to county or county borough councils, as under both the Majority and Minority Report, no transfer of the Poor-law Medical Service to the health committee as under the Minority Report, and no reference to the enlarged provident dispensary system as recommended by the Majority, are for the serious consideration of such members of the medical profession who would be most affected by these suggested changes. With regard to their patients, improvement in their treatment and the obtaining of better results with economy and increased certainty are the objects common to all the recommendations made, and the medical man, whether engaged in the Poor-law service or outside it, is entitled to study questions relating to the administrative authority and the area to be administered from a personal as well as from a public point of view.

In the first place, Mr. Booth divides the areas to be administered into two classes—viz., (1) urban groups, to be such as comprise a conterminous population socially and industrially inter-connected of not less than 250,000; (2) the remaining unions, which would obviously not be, in most cases, either entirely rural or urban, to be arranged in convenient groups to contain about 500,000. The effect of the groupings thus recommended is very clearly summarised by the author in two maps, to which reference should be made by all who desire fully to understand his proposals.[3] One of them gives a bird's-eye view of the existing county and borough areas of England and Wales, and the other of the areas suggested by Mr. Booth for the grouped unions. A glance will show the nature of the proposed areas and the great difference between them and those ruled by county and borough councils. Attention may be called in particular to Wales and to the north-western corner of England. Wales under Mr. Booth's scheme would be divided into one urban area (in the extreme south) and two non-urban areas, each having a population of less than 500,000, would suffice for the rest of the country. Under the county and borough council system there would be three county boroughs as self-contained independent areas and 13 counties. In the northern district referred to Mr. Booth would convert into four areas (three urban and one non-urban) the whole of the counties of Northumberland, Cumberland, Westmorland, and Lancashire, the urban groups being confined to the southern portion of Lancashire. Under the other system there would be four areas under county councils and about a dozen under borough councils. From these two examples, and still more from a study of the maps, it will be seen that the question has to be considered whether the advantage of larger areas, involving greater economy of administration and greater ease in classifying, may not be counterbalanced by the disadvantage of greater distances to be traversed (*a*) by the objects of assistance on their way to and from special institutions, and (*b*) by those engaged in administration, as members of the Poor-law boards of grouped non-urban unions.

The election of the Poor-law authorities in the areas described above might, according to Mr. Booth's suggestion, be as follows. The existing parish areas to be retained as the units of the unions, and the existing unions as the units

[1] THE LANCET, April 16th, p. 1076.

[2] Report of the Royal Commission on the Poor-laws, p. 672.

[3] Mr. Booth's scheme will shortly be published by Messrs. Macmillan and Co. at 1s. net in an octavo volume which will contain these maps.

to be grouped under Poor-law boards. A Poor-law board to be formed for each group of unions, but with difference of constitution as between the great urban groups and the others. The Local Government Board to be represented on the Poor-law boards by nominees proportionate in numbers to the exchequer grants given, otherwise the boards to consist (1) in the urban groups, of members elected for the purpose, the existing union areas being accepted as electoral areas; and (2) in non-urban groups, the chairman or vice-chairman of each union, with one other guardian (if the total number to compose the board will permit of it) to constitute the joint Poor-law board of the group. Mr. Booth is in favour of the boards being as small in numbers as may be consistent with efficiency. In urban unions the management of all institutions to be centralised, and detailed administration of relief to be by local committees composed of members of the board, and of co-opted nominees. In non-urban areas the institutions to be classified and managed by the joint board, and the out-relief to be administered by the guardians of the individual union under rules made by the joint board and approved by the Local Government Board. Under the jurisdiction of the Poor-law boards of the grouped unions Mr. Booth would bring all the destitute now dealt with by the unions acting singly, with the exception of those mentally deranged or suffering from any degree of feeble-mindedness that results in destitution. These, he suggests, might be removed from the Poor-law, but he questions whether any such course need have been contemplated if a strong and uniform administration of the Poor-law extended over large areas could have been relied upon.

This outline will suffice to indicate the nature of Mr. Booth's scheme and to enable members of the Poor-law medical service to form opinions as to how it would be likely to develop in matters of detail. The author of it himself presents it briefly and without any of the elaboration to be found in the Majority Report or of the advocacy which distinguishes that of the Minority. He puts it forward, as he says, in the form of suggestions only, republishing memoranda already included in Vol. XII. of the Appendix to the report of the Royal Commission with the addition of a few notes. We have not referred to the elaborate table of statistics included in the volume now before us, which, we understand, will not be found in the shilling volume already mentioned. They are instructive and of great value in making a complete study of the points dealt with in them, but are not necessary to those seeking to grasp the general principle of the plan proposed.

With regard to the treatment of the sick, Mr. Booth is not inclined to support the recommendation that they should be removed from the Poor-law and should be entrusted entirely to the authority already responsible for the public health. He asks whether treatment by the public health authorities is to be entirely gratuitous, and suggests that the system of aid apparently desired should be compulsory if it is to be effective, calling attention to the sacrifice of liberty which it would demand and the difficulty of recovering payment for the treatment afforded. Mr. Booth is of the opinion that whatever it may be possible to do in the direction of assigning the sick poor to the public health authority, and so preventing destitution and eliminating the Poor-law, a residue will remain that cannot properly be thus dealt with; that there must be Poor-law institutions, and that if there is to be only one authority it must be that of the Poor-law reorganised in sufficiently large areas and able to deal with every kind of need according to its character. He questions the material advantages claimed for a single authority, and asks whether the divided action of the three systems (Public Health, Poor-law, and voluntary effort) is necessarily injurious, expressing the hope of a harmonious coördination of them. In a memorandum which follows his statistical tables (Memorandum C. I.) Mr. Booth observes that it is in supplementing the general medical system of the country and not in supplanting it that the Poor-law finds its proper sphere, and he suggests that organisation and coöperation will meet difficulties of overlapping between the Poor-law, voluntary agencies, provident dispensaries, and sick clubs. He considers that the Poor-law must give relief to those who, needing it, fail to obtain assistance in any other way, and that conferences between the representatives of voluntary institutions and Poor-law representatives would tend to make clear the position of the Poor-law on the medical side. In short, Mr. Booth is not anxious to make any drastic change. His scheme is one having for its object the utilisation of existing agencies and the increase of their efficiency rather than the substitution of new ones for them, and he does not aim at or favour the enlargement of the sphere of the Poor-law either in the matter of aid to the sick or of the other subjects with which it is concerned. Coming as they do now, after the public has accustomed itself to the demands for drastic change made in the Majority Report, and still more so in that of the Minority, Mr. Booth's proposals will not, perhaps, meet with the amount of attention which assuredly they would have enjoyed if they had been incorporated in the original Blue-book. In their retention of much that has been vigorously denounced, in their claim for the adaptation of existing machinery and their obvious tendency to render unnecessary "the breaking up of the Poor-law," they would meet in the form of a Bill presented to Parliament with a very hostile reception from a large section of the political world. In their present form, moreover, they are perhaps undesirably destitute of detail and free from elaboration of fact and argument. They constitute, however, a notable contribution to the great question at issue and one particularly interesting to the medical profession, when the more radical changes proposed in the other two schemes are taken into consideration.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

A QUARTERLY meeting of the Council was held on April 14th, the PRESIDENT, Mr. BUTLIN, being in the chair.

A letter, dated March 3rd, 1910, from the Privy Council was considered. It communicated a resolution of the Executive Committee of the General Medical Council adverse to the proposal of this College to omit certain words from the conclusions adopted by the General Medical Council in regard to the Anæsthetics Bill, 1909. It was resolved to reply as follows:—

That the receipt of the letter from the Privy Council communicating the resolution of the Executive Committee of the General Medical Council be acknowledged, and that the Lord President be informed that the Council of the Royal College of Surgeons of England do not regard the contingency put forward by the Executive Committee of the General Medical Council as likely to arise. The Council of the College does not contemplate, and their experience as operating surgeons does not lead them to suppose, that dentists will be asked to administer an anæsthetic in general surgical practice other than in slight operations and on rare occasions, but they do think it will be opposed to the advantage of the public and prejudicial to the convenience of medical practitioners, especially in country districts, if it is made illegal for dentists to administer nitrous-oxide gas (and the other anæsthetics, if any, to be specified as employable by them) for operations performed by qualified medical practitioners. The Council desire to draw the attention of the Lord President to the fact that their body consists of surgeons actively engaged in operative surgical practice, whereas the Executive Committee of the General Medical Council, which dissented from the alteration proposed by the Council of the Royal College of Surgeons, consisted, with only two exceptions, of members not engaged in the practice of surgery.

The Jacksonian Prize for the year 1909 was awarded to Mr. W. Girling Ball, F.R.C.S., for his dissertation on "The Treatment of Surgical Affections by Vaccines and Antitoxins." It was resolved that the subject for the Jacksonian Prize for the year 1911 should be "The Diseases of the Pancreas, with Special Reference to their Surgical Treatment."

The Triennial Prize was not awarded. It was resolved that the subject for the next Triennial Prize should be "The Anatomy and Physiology of the Pituitary Body, and the Relationship with Disease of its Abnormal and Morbid Conditions."

The two following Members of 20 years' standing were elected Fellows. Mr. John Reuben Lunn, resident medical superintendent of the St. Marylebone Infirmary; and Mr. Andrew Melville Paterson, professor of anatomy, University College, Liverpool.

It was resolved to award the honorary medal of the College to Dr. Robert Fletcher, M.R.C.S., of Washington, U.S.A., in recognition of his distinguished labours in connexion with the publication of the Index Medicus and the Index Catalogue of the Library of the Surgeon-General's Office, Washington.

The PRESIDENT reported the delivery of two Hunterian

Lectures by Dr. C. Bolton and two by Mr. George Coats, and one Arris and Gale Lecture by Mr. Sidney Scott.

Diplomas of Member were conferred upon the undermentioned gentlemen, who have now complied with the necessary byelaws, having previously passed the examinations of the Conjoint Board:—Noel Leicester Clarke, B.A. Cantab., Cambridge University and London Hospital; Andrew Samuel Moorhead, M.B. Toronto, Toronto University and London Hospital; and George Ernest Vilvandré, A.C.P., London Hospital.

WOMEN RESIDENTS IN GENERAL HOSPITALS.

A MANCHESTER DISCUSSION.

THE Medico-Ethical Society of Manchester had as visitors at its session of Tuesday (April 12th) some 20 members of the Northern Association of Medical Women (Manchester branch) to discuss the question of the admission of women to resident posts in general hospitals. The topic has a special interest for Manchester, of course, in view of the recent refusal of the Manchester Royal Infirmary Board to admit women graduates to resident posts in that institution—a refusal that has brought upon that body criticisms from many sources, medical and other. Sir WILLIAM J. SINCLAIR presided over a very good muster of members, for it was expected that the debate would prove lively.

The case in favour of the admission of women was "led" by Dr. MARGARET MERRY SMITH, inspector of midwives in Manchester, who dealt with the subject very fully in a paper. First she outlined the history of medicine as a profession for women, mentioning that there was a woman on the first Medical Register—so far back as 1859. It was no new thing, therefore. Dr. Merry Smith then went on to deal with the present position of women in medicine, first as students, next as graduates. She described the "facilities" offered at various medical schools for the study of medicine by women, and, summing up, expressed the opinion that on the whole they compared favourably with those open to men. It was not till after graduation that the medical woman's difficulties began. At this point her opportunities, which so far had been virtually equal to a man's, became less good, though, fortunately, they were improving. Her attempts to get general experience in the form of general hospital work brought her face to face with such objections as "lack of accommodation," "woman's inability to agree with ward sisters," and so on—objections which she thought might be put at their true worth in one word—prejudice. The whole question as to the admission of a woman to a resident post in a general hospital rested on this: Was she a fit and proper person? Did she possess the same qualities as would entitle a man to hold such a position? This depended on three things—record of work, experience, and the personal character of the individual. As to the record of work, women's college records might be, and were often, just as good as men's; as to experience, they were handicapped for senior posts, but for junior posts they had equal experience with men—namely, *nil;* and as to personal character, women had the same common-sense, kindness, and physical capacity for the work as men had. Women had been found to get on with their colleagues just as well as men—neither better nor worse. Relations with ward sisters were not always so strained as was suggested. Surely it was personality and not sex that mattered. As to the argument that women themselves object to a woman doctor, it was a fact that however they might do so in theory, in practice they accepted her. And as to the suggestion that for a woman to attend to a male patient was shocking to male modesty, it must not be forgotten that the argument cut both ways. Ability and special skill were, after all, the whole basis upon which medical attendance, by man or woman, depended. Women doctors had come to stay, said Dr. Merry Smith in conclusion, and that being accepted it was only right and proper they should be given ample opportunities for fitting themselves for their work.

Dr. C. MACFIE, speaking in support of the principle, made the same point as Sir William Sinclair had made in introducing Dr. Merry Smith. He said that in admitting women to medical schools they admitted them to all positions a male medical student might occupy. Dr. Macfie added that the only argument he had heard against women doctors, or one of the few that had attracted his attention, was based on the ground of the "neurotic element" in women. He fully supported the admission of women doctors to all positions that men doctors might occupy, but he thought it was a fact that women were less able to rise to an emergency than men.

Dr. C. G. L. SKINNER thought that where the highest courage was wanted women were the equal of men, though they might not show up so well in minor emergencies. History supported his contention. Calmness in emergency was an acquired thing—acquired by training, experience, and heredity even. With the greater opportunities for development that women now had he did not doubt that they would soon be in every way man's equal in this respect, if not his superior.

Sir WILLIAM SINCLAIR then called for any views there might be in opposition to those put forward. None were forthcoming and it was gathered that all the people present, both men and women, were in favour of the proposition. This seemed to take the gathering by surprise and to cause some disappointment, particularly to the ladies, who had come in numbers to champion their cause, some of them well primed with facts and modern instances.

As the debate was in danger of petering out altogether, Sir WILLIAM SINCLAIR called on one member after another by name, and each under mild protest attested his full agreement with the case put forward by Dr. Merry Smith. But this they did in various picturesque ways.

Dr. E. VIPONT BROWN, whom Sir W. Sinclair facetiously styled "the leader of the opposition," said that to admit women to the fuller training of a general hospital after admitting them to medical schools was the only logical position that anyone could take up. To defy the logic of this was "absolute cheek."

Mr. W. F. DEARDEN said that if the suggestion that women should be confined to hospitals for women and children was adopted it would be only logical to suggest a similar restriction for men; and that, a subsequent speaker, Mr. F. FARROW, pointed out, would mean the limitation of men to men and, say, old women, who would be about an equivalent for the children.

Sir WILLIAM SINCLAIR here remarked that the suggestion made in "a certain place" that women doctors should stick to diseases of woman was to him appalling.

Mr. FARROW also attributed the prejudices of lay boards to medical women to the "arrant conservatism" of the nation, and he thought it behoved the medical profession to educate people "out of it."

Dr. A. W. W. LEA spoke of that meeting as an instance of the change that had come over medical men in their attitude towards medical women since the day when Sir William Jenner resigned from the Council of the British Medical Association rather than agree to the admittance of women.

Mr. L. SAVATARD differed from Dr. Macfie in thinking the neurotic element was more common in women. For his own part he had come across just as much of it in men.

Dr. OLIVE CLAYDON, Dr. CATHERINE CHISHOLM, Mr. C. R. O. GARRARD, Dr. FRANCES HARPER, and Dr. A. C. GEORGE also spoke.

THE MEDICAL CURRICULUM OF THE UNIVERSITY OF BRISTOL.—Concurrently with the introduction of examinations for degrees, consequent on the change from a university college to a university, it has been found advisable to make certain changes in the arrangements for teaching medicine and the allied subjects in the Bristol school. Whole-time demonstrators of anatomy and physiology have for the first time been appointed. Arrangements for clinical teaching at the Royal Infirmary and General Hospital have been devised in order to bring these two institutions into closer coördination than before, and to provide students with a series of clinical demonstrations in the wards and in the general and special out-patient departments. The practice of these latter departments has been further thrown open to students by the institution of various clerkships and dresserships, and the Children's Hospital receives a more definite status as a teaching centre than heretofore.

Public Health.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Borough of Sutton Coldfield.—The facilities which exist in this borough for the gratuitous examination at Birmingham University of swabs from suspected cases of diphtheria are being appreciated by the medical practitioners, but Dr. A. Bostock Hill utters a word of caution as to the importance of securing at least two negative reports before a case is regarded either as not diphtheria or as free from infection. This is certainly a wise precaution, as it is to be feared that in many places practitioners are content with one negative report. Dr. Hill also draws attention to the importance of making use of the free provision of antitoxin. As we have on several occasions pointed out in these columns, it is astonishing that many cases of diphtheria in different parts of the country are found on admission to isolation hospitals not to have had antitoxin administered to them, a fact which is a very serious criticism upon the attending practitioner. Dr. Hill is not in favour of the promiscuous closing of schools in connexion with the spread of infectious diseases, and as a general rule he only regards closure as necessary with the view of preventing the spread of measles in the case of infant schools. He thinks it best to close such a school for a fortnight on the appearance of the first two or three cases in the hope that any children then infected will develop the disease before the school is reopened.

Chelmsford Rural District.—During 1909 a complaint was made by one of the parish councils in this district that there was a deficiency of cottage accommodation. The district council being asked to provide cottages under the Housing of the Working Classes Act, Dr. J. C. Thresh made an inquiry into the circumstances of the parish, but was unable to report that there was serious lack of cottages. The existing rents appeared low—some at £5 and even £4—and the labourers alleged that if new houses were provided they could not afford to occupy them. But Dr. Thresh reported that in the interests of morality larger cottages are desirable, and that the existing conditions drive all the brighter young adults out of the parish. He also reminds the district council that cottages erected by sanitary authorities cost much more than those erected by private persons, although he is unable to explain why this is so. He clearly thinks, and there is much to be said for the view, that the farmers should provide cottages for their labourers, and he gives an example of farms in another parish where, with a total acreage of 950 acres belonging to one owner, there is not a single cottage belonging to the farms. In this connexion he observes that so long as there is no legal power to compel landowners to provide their quota of cottages so long will Housing Acts prove inefficient, since the parishes naturally object to being asked to provide cottages for the benefit of the landlords. This lack of decent cottages drives, Dr. Thresh adds, all the best blood out of the villages and leads to the farmers preferring to employ unmarried men or men with small families. In his opinion it is to be regretted that tents and sheds do not come under the new Housing Act, since a family may be turned out of an old cottage and occupy a tent, thus accentuating difficulties which have already arisen in connexion with these tent dwellers.

Borough of Reigate.—Dr. A. E. Porter furnishes in his current annual report a useful illustration of the difficulty of administering small isolation hospitals in the absence of a resident medical officer. He points out that in the Reigate Hospital there is no observation ward and no provision for cases of mixed infection. This hospital is now used, not for the isolation of all cases, but for cases selected for admission on the basis of their home conditions. In connexion with the cases of scarlet fever discharged last year from this hospital, 76 in number, there were 10 "return" cases, while among the 22 cases treated at home but 1 "return" occurred, this patient having been allowed, against instructions, to sleep in the same room as his brother on the night after he left the sick room. Apparently all these "return" cases occurred before the selective method of admission referred to above was practised, and Dr. Porter is curious to see how far the "return" case incidence will be affected by the change. The bacteriological examination of the throats of school-children is carried out in a very systematic manner in this district and some instructive results have been obtained. For example, one child who was treated at home had a mild attack of diphtheria on Oct. 8th, 1908, and swabs were found to yield the typical bacillus until July 25th, 1909, notwithstanding all kinds of local treatment. There seems to have been no doubt as to the identity of the bacillus, which on March 5th was virulent for guinea-pigs at the Lister Institute. Some administrative trouble was caused at the hospital in the early part of 1909 by diphtheria infection in the scarlet fever wards, which was regarded as due to the admission of scarlet fever patients with the double infection. Unfortunately, the fact was only discovered when several of the patients had been discharged, and consequently the throats of all the 31 patients who had returned home within the previous two or three months were examined, with the result that 10 were found to be infectious while 8 more had Hofmann's bacillus in either the throat or the nose. The other inmates of the invaded houses were also examined and three were found to be harbouring the diphtheria bacillus. Nine of the healthy infectious persons were removed to the diphtheria wards, and it is not clear whether any of them developed the disease either from the bacilli they were carrying on admission or from any which they may have acquired afterwards. It is now the practice at this hospital to examine bacteriologically all scarlet fever patients on admission, those having a double infection being isolated in the small block designed for enteric fever. Dr. Porter is to be congratulated on having set out the facts so candidly, and everyone who has had experience of the matter will agree with him that "the administration of a hospital for infectious diseases is not so simple a matter as might appear on the surface," and it is probable that the more bacteriological examination is made use of the more difficult administration will become.

Borough of Southend.—Dr. C. G. Pugh estimates the population of this borough at the middle of 1909 at 61,268, but the average resident population during the summer months is considerably above this figure owing to the influx of visitors, excursionists, and servants. The birth-rate for 1909, calculated on the above estimate, was 18·59 per 1000, and the death-rate 10·29 per 1000. The number of uncertified deaths was 6·9 per cent. of the total deaths, and Dr. Pugh finds it difficult to explain satisfactorily this high rate. He thinks that inquests should be held as to the cause of death of all children unless a medical certificate is forthcoming, and he furnishes details as regards the death of an adult which show how easy it may be for people to die from negligence or poisoning when no inquest is insisted upon. The infantile mortality, which, as is the case of so many other towns, has shown a marked decrease during quite recent years, amounted in 1909 to only 74·62 per 1000 births, a circumstance which was almost entirely due to the non-occurrence of summer diarrhœa. There were nine deaths amongst illegitimate children—i.e., a rate of 243 per 1000, as compared with a rate of 69 per 1000 amongst legitimate births. Only one of the nine children who died was breast-fed. For the first time in the history of the borough there was no death from enteric fever, while only one indigenous case of this disease was notified. In 1908 there were 20 cases with one death, and Dr. Pugh points out that as the result of modernising the drainage in the older portion of the town, and of the care to prevent the consumption of polluted shell-fish, a marked fall in the prevalence of enteric fever took place between 1893 and 1904, the indigenous case-rate having been 9·7 per 1000 in the former year as against 0·23 in the latter. Since then the incidence of the disease has remained approximately constant, the majority of cases which have occurred being associated with the consumption of oysters either picked up by the patient or his friends from the foreshore of the Thames or bought from street hawkers who have obtained them in a similar fashion. At Dr. Pugh's suggestion watchers were employed by the corporation in 1908 to prevent unauthorised persons from collecting shell-fish either for their own consumption or for purposes of sale, but as this precaution proved ineffectual the pier committee leased the foreshore to the Southend Shell-fish Company at a rental of £10 per annum, it being one of the conditions of the lease that no shell-fish, except cockles, should be removed from the foreshore by the tenants except for being placed in suitable beds for cleansing; while as regards cockles it was stipulated that

they should be boiled, steamed, or otherwise treated by the tenants so as to render them sterile from a bacteriological point of view. It appears that the company are faithfully carrying out their obligations, and they have on several occasions taken proceedings against offenders. The inference would seem to be that steamed cockles are without danger to the consumers, and it would be instructive to learn what bacteriological tests have been applied, and the locality of the approved beds to which the other shell-fish are removed for cleansing purposes, as well as the findings of the bacteriologists in connexion with shell-fish removed from such beds. Much of the credit for dealing with the Southend shell-fish difficulty is due, Dr. Pugh adds, to the efforts of the previous medical officers of health, Dr. A. Clough Waters and Dr. J. T. C. Nash. Reviewing the past prevalence of enteric fever in Southend Dr. Pugh thinks that although the consumption of polluted shell-fish was unquestionably the main cause of its excessive prevalence, it is possible that other factors, even now not definitely recognised, may have assisted towards the same end, but whether this was so or not such factors are certainly not now operative.

ANNUAL REPORTS OF SCHOOL MEDICAL OFFICERS.

Borough of Richmond.—The school medical officer in this district is the medical officer of health, Dr. J. H. Crocker, an assistant school medical officer having been appointed for the purpose of the medical inspection of the children. During 1909 there were 885 children inspected in the infants' department and 318 in the upper departments, i.e., 1203 in all. The total number found with some defect and not undergoing any treatment was 27 per cent. of those examined, or, excluding the children with defective teeth, 10 per cent. The facilities which obtain in Richmond for the treatment of the defects discovered are considerable, and they embrace the out-patient department of the Richmond Royal Hospital, which includes an ophthalmic department, general practitioners who have devoted special attention to vision estimation and who examine for a small fee, and other medical institutions, such as the Richmond Dispensary and the Petersham Dispensary. With all these facilities for treatment it is not surprising to find that, excluding cases of defective teeth, at least 50 per cent. of the defective conditions were immediately attended to by the parents. As regards the dental conditions the results were less satisfactory, as out of 206 children with defective teeth 89 could not be accounted for owing to the fact of their having left school, while of the remaining 117 only 18 had been to a dentist. Systematic arrangements are made in Richmond for the disinfection of the elementary schools, each school being supplied with a spraying apparatus and a quantity of formalin. At least once a term the rooms, desks, and suchlike are sprayed, and a similar disinfection is carried out after the occurrence of any case of infectious disease amongst the scholars.

County Borough of Bournemouth.—Dr. A. D. Edwards, who is the deputy school medical officer, in presenting his report for 1909, states that as regards medical treatment it was found upon visiting the homes of the patients that 382 out of the 770 defects requiring treatment had already received attention and that arrangements for treatment had been made in the case of an additional 75. As he claims, these conditions are by no means unsatisfactory at this early stage. Dr. Edwards reserves judgment as to the quality of the treatment received and is content to state that 59·3 per cent. of the cases have received attention from qualified men. With reference to the question of tuberculosis and school children Dr. Edwards states that although he was unable to detect much definite tuberculosis amongst the children there were many whom he considered to be in the incipient stage of the disease, and these children he has marked for repeated examination. As he points out, these are the children who in Germany—and, we may add, largely in France too—would be drafted off to open-air schools or seaside sanatoriums. We should, however, be interested to learn what are the signs and symptoms of the condition which Dr. Edwards regards as incipient tuberculosis. As is well known, some of the French authorities claim to have discovered a pre-tuberculous condition in a large number of Parisian children, but English practitioners cannot recognise this condition as so definite a one that rules for its diagnosis can be laid down.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8696 births and 4872 deaths were registered during the week ending April 16th. The annual rate of mortality in these towns, which had steadily increased in the four preceding weeks from 13·5 to 14·9 per 1000, further rose to 15·0 in the week under notice. During the 13 weeks of last quarter the annual death-rate in these towns did not exceed 15·0 per 1000, and was no less than 3·0 below the average rate in these towns in the four preceding corresponding quarters; in London the mean rate during last quarter was only equal to 14·9 per 1000. The lowest reported annual rates of mortality in the 77 towns during last week were 4·2 in Hornsey, 6·8 in King's Norton, 7·6 in Burton-on-Trent, and 8·3 in East Ham and in Tynemouth; the rates in the other towns ranged upwards, however, to 20·3 in Newport, 20·7 in Liverpool, 21·0 in Merthyr Tydfil, and 23·3 in Stockport. In London the recorded death-rate last week did not exceed 14·8 per 1000. The 4872 deaths registered in the 77 towns during the week showed a further slight increase of 15 upon the numbers returned in the four preceding weeks, and included 383 which were referred to the principal epidemic diseases, against 317, 332, and 362 in the three previous weeks; of these 383 deaths, 143 resulted from whooping-cough, 117 from measles, 39 from diphtheria, 35 from scarlet fever, 34 from diarrhœa, and 15 from enteric fever, but not one from small-pox. The mean annual rate of mortality in the 77 towns during the week from these epidemic diseases was equal to 1·2 per 1000, against 1·0 and 1·1 in the two preceding weeks. No death from any of these epidemic diseases was registered last week in Leicester, Walsall, Hornsey, Northampton, or in nine other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·0 in Hastings and in Bootle, 4·3 in Devonport, and 5·2 in Merthyr Tydfil. The fatal cases of whooping-cough in the 77 towns, which had steadily increased in the seven preceding weeks from 100 to 151, declined again last week to 143, but caused annual death-rates equal to 1·4 per 1000 in Liverpool and in Grimsby, 2·3 in Hastings, and 2·5 in Devonport. The deaths from measles, which had been 78, 93, and 104 in the three preceding weeks, further rose last week to 117; the highest death-rates from this disease during the week were 1·2 in Bradford, 1·7 in Burton-on-Trent, 2·2 in Bootle, and 5·2 in Merthyr Tydfil. The 39 deaths referred to diphtheria showed an increase of 4 upon the number returned in each of the two preceding weeks, and included 13 in London and its suburban districts, 5 in Birmingham and King's Norton, 7 in Manchester and Salford, 3 in Sheffield, and 2 both in Leeds and in Sunderland. The 35 fatal cases of scarlet fever also somewhat exceeded the numbers in recent weeks; 4 occurred in Birmingham and in Liverpool, 3 in Leeds, and 2 in Walthamstow, in Portsmouth, and in Nottingham. The deaths attributed to diarrhœa during the week were 34, against 30 and 27 in the two previous weeks. The 15 deaths referred to enteric fever were fewer by 2 than the number in the preceding week; 8 were returned in London and 2 in Derby. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily declined in the 26 preceding weeks from 2819 to 1554, had further fallen to 1535 on April 16th; 197 new cases of this disease were admitted to these hospitals during last week, against 158 and 166 in the two preceding weeks. The Metropolitan Asylums Hospitals contained no small-pox patient on Saturday last. Of the 1387 deaths registered in London during the week under notice 312 were referred to pneumonia and other diseases of the respiratory system, showing an increase of 31 upon the number in the previous week; they were, however, 23 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 42, or 0·9 per cent., of the deaths registered in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during the week were duly certified in Leeds, Sheffield, Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 51 other smaller towns;

the 42 uncertified causes of death in the 77 towns included 10 in Liverpool, 4 in Gateshead, and 3 each in Coventry, Stoke-on-Trent, St. Helens, and Rochdale.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 934 births and 669 deaths were registered during the week ending April 16th. The annual rate of mortality in these towns, which had been equal to 15·3, 18·1, and 18·2 per 1000 in the three preceding weeks, further rose to 18·5 in the week under notice. During the 13 weeks of last quarter the annual death-rate in these towns averaged 17·5 per 1000, and exceeded by 2·5 the mean rate during the same period in the largest English towns. The annual death-rates during last week in these eight Scotch towns ranged from 5·6 and 9·0 in Perth and Aberdeen, to 26·9 in Greenock and 28·5 in Dundee. The 669 deaths from all causes in the eight towns during the week showed a further increase of 10 upon the numbers in the two previous weeks, and included 97 which were referred to the principal epidemic diseases, against 77, 82, and 123 in the three preceding weeks. These 97 deaths were equal to an annual rate of 2·7 per 1000; the mean death-rate from the same diseases in the 77 English towns last week did not exceed 1·2 per 1000. These 97 deaths in the Scotch towns last week included 64 from measles, 15 from diarrhœa, 8 from diphtheria, 6 from whooping-cough, 2 from scarlet fever, and 2 from "fever," but not one from small-pox. The fatal cases of measles, which had been 43 and 74 in the two preceding weeks, declined again to 64 last week; they included 29 in Dundee, 17 in Glasgow, 9 in Greenock, 6 in Edinburgh, and 2 in Leith. The 15 deaths attributed to diarrhœa showed a further decline from the high numbers in the two previous weeks; 6 were returned both in Glasgow and in Dundee. The 8 fatal cases of diphtheria showed a decline, but included 4 in Glasgow and 2 in Paisley. Of the 6 deaths from whooping-cough, corresponding with the number in the previous week, 4 occurred in Glasgow. The 2 fatal cases of scarlet fever were fewer than in any recent week. The 2 deaths referred to "fever" were both returned in Edinburgh, one being certified as enteric and one as cerebro-spinal meningitis. The deaths in the eight towns referred to diseases of the respiratory system, which had been 122 and 114 in the two preceding weeks, rose again to 126 in the week under notice, but were 9 below the number in the corresponding week of last year. The causes of 18, or 2·7 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death did not exceed 0·9 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 644 births and 512 deaths were registered during the week ending April 16th. The mean annual rate of mortality in these towns, which had been equal to 20·7 and 23·2 per 1000 in the two preceding weeks, was again 23·2 in the week under notice. During the 13 weeks of last quarter the annual death-rate in these Irish towns averaged 21·8 per 1000, whereas the mean rate during the same period did not exceed 15·0 in the 76 largest English towns, and 17·5 in the eight principal Scotch towns. The annual death-rate during last week was equal to 21·5 in Dublin, 24·9 in Belfast, 22·6 in Cork, 20 4 in Londonderry, 20·5 in Limerick, and 33·1 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish town districts was equal to 23·8 per 1000. The 512 deaths from all causes in the 22 town districts last week corresponded with the number in the previous week, and included 39 which were referred to the principal epidemic diseases, against 26 and 34 in the two preceding weeks; these 39 deaths were equal to an annual rate of 1·8 per 1000; in the 77 English towns the mean rate during last week from the same diseases did not exceed 1·2 per 1000, but in the eight Scotch towns it was equal to 2·7. The 39 deaths from these diseases in the Irish towns last week included 17 from measles, 9 from whooping-cough, 5 from diarrhœa, 5 from typhus, 2 from other forms of "fever," and 1 from diphtheria, but not one either from scarlet fever or small-pox. The fatal cases of measles, which had been 6 and 11 in the two previous weeks, further rose to 17 last week, all of which occurred in Belfast. The 9 fatal cases of whooping-cough, however, were fewer by 6 than the number in the previous week, but included 5 in Belfast and 2 in Dublin. Of the 5 deaths from typhus, 2 occurred in Dublin, 2 in Waterford, and 1 in Galway. Two of the 5 deaths from diarrhœa and a fatal case of enteric fever were returned in Dublin. The deaths in the 22 town districts referred to pneumonia and other diseases of the respiratory system, which had been 102 and 129 in the two preceding weeks, declined again to 121 last week. The causes of 30, or 5·9 per cent., of the deaths registered in the Irish towns last week were not certified; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent., and in the eight principal Scotch towns it was equal to 2·7 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: E. R. Dimsey, D.S.O., to the *St. Vincent*, on commissioning; G. G. Borrett, to the *Lord Nelson*; L. Bidwell, to the *Crescent*; J. Andrews, to the *Exmouth*; W. J. Colborne, to Pembroke Dockyard; C. S. Woodwright, to the *Leviathan*; and C. Bradley, to the *Roxburgh*. Staff-Surgeons: F. F. Lobb, to the *Ganges*, for Shotley Training Establishments and for duties in connexion with physical training; J. Boyan, to the *Pembroke*, for R.N. Barracks, temporary; R. M. Richards, to the *Vivid*, additional, for the *Theseus*; and H. C. Whiteside, to the *Vivid*, additional, for disposal. Surgeons: A. T. Rivers, to the *St. Vincent*, on commissioning; H. S. Turner, to the *Lord Nelson*; and J. E. Johnston, to the *Ringdove*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant Wilfrid W. Treves is seconded under the provisions of Article 300, Royal Warrant for Pay and Promotion, 1909 (dated April 1st, 1910).

Lieutenant-Colonel H. Cocks, on return from a tour of service in India, has been appointed to the Western Command. Lieutenant-Colonel S. R. Wills has been posted to the Seventh (Meerut) Division, India, and appointed to command the station hospital at Agra, United Provinces. Lieutenant-Colonel H. W. Austin has been transferred from Glasgow to Aldershot. Lieutenant-Colonel F. G. W. Gordon-Hall, from Muttra, has joined at Glasgow for duty. Lieutenant-Colonel C. H. Burtchaell, Staff Officer to the Principal Medical Officer, Irish Command, has been selected for the appointment of Assistant Director-General, Medical Department, War Office. Lieutenant-Colonel D. M. Saunders, Sanitary Officer, Dublin District, has been posted to Cork, with effect from April 13th. Lieutenant-Colonel H. A. Haines, from Fyzabad, has been posted for duty to the Southern Command, and Lieutenant-Colonel H. P. G. Elkington, from Jhansi, has been appointed to the Irish Command. Major C. Dalton has been selected to officiate as Staff Officer to the Principal Medical Officer, Irish Command. Major W. D. Erskine has been transferred from York to Strensall. Major J. D. Macpherson, from Meerut, has been appointed to command the station hospital at Pachmari. Major A. F. Tyrrell, from Cork, has been posted to Queenstown. Major T. W. Gibbard, from Dagshai, has been appointed to London District and placed in charge of the Military Hospital at Rochester-row. Major T. B. Beach, from the Royal Arsenal, Woolwich, has been transferred for duty in the Aldershot Command. Major John M. Buist, on arrival from Wynberg, Cape Colony, has been posted to the Southern Command. Major G. E. F. Stammers, Sanitary Officer, Southern Command, has had his appointment extended by six months. Major E. B. Steel has been transferred from Neemuch to Jhansi. Major C. H. Hopkins has been transferred from the Indian to the Home establishment. Major G. B. Riddick has been appointed a specialist in electrical science to the Burma Division. Captain O. L. A. Webb, from the Royal Army Medical College, has embarked for West Africa. Captain E. G. Ford, from Bradford, has been posted to Rawalpindi for duty. Captain J. H. Campbell has been transferred from Allahabad to Lucknow. Captain W. Riach has arrived home on leave from West Africa. Captain F. M. M. Ommanney, from Aden, has been posted to the Eastern Command. Captain H. H. Norman has been granted six months' leave from India.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel E. Jennings, Superintendent of the Central Prison at Bareilly, has been transferred to Fategarh, United Provinces. Lieutenant-Colonel C. N. Bensley has arrived home on leave. Lieutenant-Colonel H. Greany, Senior Medical Officer, Ceylon, has been granted two years' furlough. Major W. W. Clemesha has been confirmed in his appointment as Sanitary Commissioner of Bengal Presidency. Major C. B. Prall, superintendent of the Central Prison at Lucknow, has been transferred to Bareilly and appointed superintendent of the central prison at that station. Major G. H. Frost, in medical charge of the Fourth Gurkha Rifles, Bakloh, has arrived home on leave. Captain D. McCay has been granted one year's leave from India. Captain A. M. Fleming, Civil Surgeon at Raipur, has been placed in medical charge of the Bilaspur District. Captain J. F. Boyd has been appointed medical officer in charge of the 57th Wilde's Rifles, Frontier Force, at Bannu, vice Captain C. E. Southon. Captain H. H. Thorburn, attached to the 82nd Punjabis in the Malakand, has been granted one year's leave out of India. Captain E. C. C. Maunsell, 94th Russell's Infantry, has arrived home on leave. Lieutenant J. J. H. Nelson, medical officer attached to the 88th Carnatic Infantry, has been appointed a specialist in the Prevention of Disease at Bangalore.

TERRITORIAL FORCE.

Yeomanry.

Westmorland and Cumberland: Surgeon-Major Joseph E. Bowser resigns his commission and is granted permission to retain his rank and to wear the prescribed uniform (dated Feb. 22nd, 1910).

Royal Army Medical Corps.

3rd East Anglian Field Ambulance: Major and Honorary Surgeon-Lieutenant-Colonel Harry Thornton Challis, from the list of officers attached to units other than medical units, to be Major, with the honorary rank of Surgeon-Lieutenant-Colonel (dated Feb. 1st, 1910).

1st South-Western Mounted Brigade Field Ambulance: Robert Pounden Beatty to be Lieutenant (dated Feb. 15th, 1910).

1st West Riding Field Ambulance: Lieutenant Alexander B. S. Stewart to be Captain (dated Feb. 15th, 1910).

2nd London (City of London) General Hospital: Hugh Mallinson Rigby to be Captain, whose services will be available on mobilisation (dated March 19th, 1910).

For attachment to Units other than Medical Units.—James Leonard Joyce to be Lieutenant (dated Jan. 5th, 1910). James Mathieson Kirkness to be Lieutenant (dated Feb. 1st, 1910). Stanley Fox Linton to be Lieutenant (dated Feb. 9th, 1910). Frederick William Sydenham to be Lieutenant (dated Feb. 11th, 1910).

Attached to Units other than Medical Units.—Lieutenant David Westwood to be Captain (dated Jan. 28th, 1910). Captain Alexander Roxburgh resigns his commission (dated Feb. 22nd, 1910). Lieutenant John Allan to be Captain (dated Oct. 7th, 1909). Lieutenant Horatio W. A. Cowan resigns his commission (dated Feb. 23rd, 1910).

THE BRITISH RED CROSS SOCIETY.

The Hon. Mrs. Charles White presided at a meeting held at Aldershot on April 15th, when Sir Frederick Treves gave an address in which he urged the necessity of forming a first-aid branch of the Red Cross Society at Aldershot and Farnborough. On the proposal of Lord Winchester it was unanimously decided to form a voluntary first-aid detachment.

A meeting was held at Penarth on April 14th in support of the objects of voluntary first-aid detachments, when an address was delivered by Mr. J. Lynn Thomas, C.B. He pointed out that in the county of Glamorgan the movement had spread very rapidly, mainly owing to the active part taken in the work by Lady Plymouth. In the event of an invasion the only base hospital in the whole of Wales during mobilisation would be located at Cardiff, and it might be assumed that the rich coal-fields of the district would be the chief objective of an invading force. He had no hesitation in saying that in case of need a fully equipped hospital would be provided for the district in six days.

Correspondence.

"Audi alteram partem."

THE MIDWIVES BILL AND POOR-LAW RELIEF.

To the Editor of THE LANCET.

SIR,—Mrs. Sidney Webb, indefatigable in her advocacy of the Minority Report, sees a lost opportunity in the amending Midwives Bill now before Parliament. Mrs. Webb objects to the guardians as the channel by which the fee is paid to any medical man summoned on the advice of a midwife in a case of emergency under Rule 18 of the Central Midwives Board. The Government, she says, proposes to make these mothers into paupers; "their homes will be visited by the relieving officer with his hated inquiries; often to the detriment (as any nurse or midwife will testify) to the woman's health." She suggests that the payment be made by the sanitary authorities, meaning presumably the local supervising authorities under the Midwives Act, 1902, the councils of counties and county boroughs, for she cannot mean the local sanitary authorities, which in all rural districts are the guardians in fact under another name. The county and county borough councils, then, should decide the patient's capacity to pay.

But is it conceivable that a county council should institute new and independent machinery for the investigation of the resources of about 200 cases in a year, when these resources are already known in most cases to the relieving officers? Would it not almost certainly employ the same relieving officers for the purpose? If not, would not the inquiries, in order to be efficient, be every bit as much hated as those of the relieving officers? What, then, would be the advantage of dualising existing procedure for determining the resources of those who benefit by public medical relief?

No, Sir; the fact is that Mrs. Webb's argument is opposed to inquiries of any kind. And although the Minority Report proposes the appointment of a public assistance officer with a staff of inquiry and recovery officers—for which posts I have a shrewd idea that the present relieving officers would be successful applicants—its fundamental and logical idea is that medical relief should be free, in order that there may be no hindrance to its being invoked on every possible occasion to the benefit of the patient and so of the public health. This has been, in fact, except in a few large towns, the virtual result of every Act or regulation that has entrusted the recovery of charges to any authority other than the guardians; the cost and worry of the machinery were not equal to the sum recovered; recovery has been a dead letter.

The profession must consider the advantages and disadvantages of indiscriminate relief. But if discrimination is to be made the inquiries are bound to be hated; they must be limited to one set of officials, and if they are to be efficient they should be entrusted, as the Departmental Committee recommended (Report, Sec. 75), to "the authority primarily invested with the functions of public assistance." That authority at present is the board of guardians. In any case, if Clause 17 of the Bill becomes law the medical practitioner "shall be entitled to recover" his fee and the main obstacle to the smooth working of the 1902 Act is removed.

I am, Sirs, yours faithfully,

April 13th, 1910. F. E. FREMANTLE.

To the Editor of THE LANCET.

SIR,—I gather from the correspondence that is appearing in many newspapers that there is some misunderstanding as to the effect of Clause 17 of Lord Wolverhampton's Bill, which proposes to place upon the board of guardians the obligation of paying the fee of the doctor whom the midwife is under definite obligation to summon in case of danger. At present there is no statutory provision for the payment of the doctor. For an ordinary accident case, when he is summoned by the police, his fee is paid from municipal funds (Watch Committee). When summoned by the midwife his fee is, in Manchester, Liverpool, and some other places (under Section 133 of the Public Health Act), also paid from municipal funds (Health Committee). In neither case does the patient thereby become a pauper.

Meanwhile, on the suggestion of the Local Government Board, various boards of guardians have, under an Act of 1848, been paying the doctor's fee when he has been called in under the Midwives Act and applies to the board for his fee, though no board of guardians has yet presumed to pay the fee of the doctor called to an accident case by the police. Yet where the board of guardians makes this payment it is entered as parochial relief to the woman and her husband (who have not applied for assistance at all); the relieving officer is sent to make inquiries; the woman (and her husband) become paupers; their names are recorded as paupers; they are included in the statistics of pauperism; and they incur certain voting and other legal disabilities. Some people innocently deny this, because an Act of Parliament has said that the receipt of medical relief only shall not prevent a man from having his name entered on the register of Parliamentary electors. But all the other legal incidents of pauperism remain, together with its bad psychological reaction. Moreover, what has the Parliamentary Register to do with women?

Let no man imagine that the wrong which the Government is proposing to do to women is an imaginary one or a sentimental evil. I append a report of a recent meeting of midwives:—

A meeting was held at the East End Mothers' Home on March 8th, at which Miss Paget presided, and there was a good attendance of midwives. The question of doctors' fees was discussed. The chairman spoke on the question and then asked the midwives present to give their experience. All agreed that since the guardians of both boroughs had promised the fee when the patient was too poor to do so they had not much to complain of with regard to the doctor, but a great many of those present spoke of the way in which the relieving officer went (in some cases the same day) and worried the patients with questions as to their power to pay the fee themselves. One midwife said her patient had been so upset by the officer's visit that her temperature went up and the midwife feared she would have to send for the doctor again. In one case the father lost half a day's work because he was summoned before the board, when he said that it was impossible to pay both doctor and midwife out of his weekly wage of 21s.

The worst feature of the case yet remains to be stated. At present, even if the board of guardians does pay the doctor, the woman (and her husband) need not, if they knew their rights, give any heed to this officious action. It is, indeed, admitted by some unions that payments made under the Act of 1848 are not parochial relief, and are not recoverable. The patients cannot be forced to accept parochial relief. They need not accept it "on loan," and they are under no legal liability to reimburse the guardians at all. They could even successfully restrain the board of guardians from entering their names as paupers. The Local Government Board is aware of this. Now the Government is proposing compulsorily to make these poor people paupers, merely because the board of guardians has chosen to pay (not to them) a fee to a doctor whom Parliament (not they) has chosen to have called in.

I hope that the words "local supervising authority" (i.e., county or borough council) will be substituted for "board of guardians," and all reference to Poor-law relief omitted, thus assimilating the case to that of the doctor called in by the police to accident cases. Why should women be treated differently from men?

I am, Sir, yours faithfully,

BEATRICE WEBB.
(Mrs. Sidney Webb.)

Grosvenor-road, S.W., April 16th, 1910.

THE COMMON COLD: ITS MODERN TREATMENT.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Nov. 28th and Dec. 5th, 1908, a paper was published by Dr. R. W. Allen dealing with the treatment of the "common cold" which, happily for me, I was fortunate enough to read. Subsequently you published a letter from Mr. Brudenell Carter giving his personal experiences of this method of treatment under Dr. Allen. The perusal of the above led me to consult Dr. Allen on June 20th, 1909. The history I gave him then was that for nearly 20 years I had been a martyr to catching catarrhs at the slightest provocation. Almost every change of weather affected me. My trouble almost invariably began in the post-nasal space, and within a short time spread to the larynx and trachea. I usually had a copious secretion from the nasal mucosa and the catarrh there had spread into the Eustachian tubes. The turbinates and post-nasal space had been cauterised frequently, but without any benefit from this or any other form of treatment. I could not sit before an open window or get into the smallest draught, or attend a night-call without the inevitable cold coming on. No one could have suffered more or more continuously from those annoying chills than I did.

Dr. Allen at once made a culture from my mixed nasal and laryngeal secretions, and on June 22nd gave me an injection of—

M. catarrhalis	75 millions.
B. influenzæ	25 ,,

As this and subsequent injections were given at about 6 P.M. the after-effects of one will answer for a description of the rest. I had a commencing "cold" when the first injection was given. About 3 A.M. I woke with a headache and some feverishness. After three or four hours this passed off, and during that afternoon I found my cold had wonderfully cleared up. I had never had such an experience before, as my trouble usually hung about me for a week or two. Thereafter I received the following injections at the dates mentioned:—

2/7/09	M. catarrhalis	75 millions.
	B. influenzæ	25 ,,
20/7/09	Repeated above.	
12/8/09	M. catarrhalis	250 ,,
	B. influenzæ	100 ,,
2/9/09	M. catarrhalis	375 ,,
	B. influenzæ	150 ,,
	B. septus	125 ,,
15/9/09 27/9/09 12/10/09 2/11/09	Repeated above.	

No more injections were then given until Feb. 17th, 1910, when I received an injection of—

B. influenzæ	250 millions.
M. catarrhalis	500 ,,
Pneumococcus	100 ,,
B. septus	125 ,,

Up to Feb. 17th I had not one cold during the winter and the slight cold coming on then was quickly cut short by the last injection. In reality, then, the injections had given me four months of complete immunity, a unique experience for me, and Dr. Allen's experience leads him to believe that, at first at least, this period of immunity is as much as can be hoped for. I have had no injection since February and no cold, and the great comfort and improvement I have experienced through the treatment impels me to write this letter.

Without the least intention of being unduly optimistic, I am, from my personal experience, a ready believer in the doctrine that "the immunizer is the physician of the future."

I am, Sir, yours faithfully,

M. S. HARFORD.

Mile End, E., April 15th, 1910.

EXERCISE IN EDUCATION AND MEDICINE.

To the Editor of THE LANCET.

SIR,—In your review of Dr. Tait McKenzie's book on this subject you take exception to his explanation of "second wind," and, in my opinion, quite properly, criticise his theory. You go on to say that "second wind" is a "cardiac phenomenon." Now, Sir, while I allow that the heart is nervously excited in sympathy with any unusual muscular exertion, yet I hold that the primary cause of the sense of discomfort lies rather in interference with the circulation in the lung, and this in its turn is brought about by *want of attention* to the working of the breathing apparatus. The mind is set upon the action of the limbs and neglects, unconsciously, that of the respiratory muscles, above all, the most important, that of the diaphragm. By-and-bye the machine "finds itself." Each set of muscles does its own work and "second wind" is established.

As far as the extraordinary muscles connected with breathing are concerned, a very little consideration will show that for their free working certain fixed points are required, while in relation to movements of the limbs the converse is equally true. In this way it is plain that there is necessarily opposition between them and each has to learn how to get on without hurting its neighbour. I have made the experiment on my own person and have found if I consciously bring the extraordinary muscles into action by taking

stave off, est as I h is r,

the country is ripe for the change, it may come in the natural course of progress. The introduction of a municipal sterilised milk-supply would be an eminently satisfactory solution of the difficulty. Wherever this has been tried it has been found that the concern was a financial loss to the community. To make this business pay, the price of milk would have to be raised to such an extent that the poorer sses of the population could not afford this necessity of The strenuous opposition of the wholesale and retail llers would have to be overcome, and altogether we ider this method as being outside the pale of y.

ture to throw out one or two suggestions for n of medical officers of health.

rts could be covered and have glass panels the sides. This very simple plan would outlay, but not only would it protect ans and the measures, but it would mfort and protection of the milk- ather. ith a small can, ed on it. The sured into the and delivered proceeding e necessary it reaches to give t not so g of the would be se of the easured. r is the uld not mpared rity his ed the unt of ly this ng the

There he top e milk would s is a prose- from orities any, taken can. the —the rence, richer getting a case usually, rt of the under the eaking, no am will rise some time. lers quiescence ility. There is f the milk going ds, and this will prevent the cream that the sediment in

the milk would all come away when milk was drawn off for the first few customers. Similar arguments apply to this objection as were used in the case of the cream. The constant movement of the milk would prevent sediment to any extent taking place. Further, the tap would have to be fixed at least an inch from the bottom of the can, and any sediment that did happen to be present would have no more chance of being unfairly distributed amongst the various customers than it has at present. Education of the general public would, I am convinced, soon overcome their objections. When they found that their milk contained as much cream and as little (if not less) deposit as formerly, they would appreciate that while they were not losing anything they were gaining by getting a purer milk.

Suggestion No. 4 might be criticised on the ground that the washing of the milk cans, as already done by the farmer, is apt to be perfunctory, and that any increase in the number of cans to be washed is to be deprecated. This is an objection which, I think, can be readily and satisfactorily dealt with. If the cans were not properly and thoroughly cleaned every day, the milk put into them would soon sour. Complaints would then be made by customers to the milkman, and in his own interests he would very soon see that due care and attention were paid to this important part of his work. Irrespectively of this, the local authority, under the Dairies, Cowsheds, and Milkshops Orders, has power to make and enforce regulations for, amongst other things, securing the cleanliness of milk vessels. This being the case, efficient inspection of the dairies would ensure due attention to the cleanliness of the milk cans.

I do not claim that any of the methods suggested would give a supply of sterile milk, but it would diminish the risks of contamination and enable us to get a milk which would keep longer than the milk as at present supplied keeps. Farmers, on the whole, are a reasonable body of men, and I feel sure that if their attention was drawn to the risks associated with their present methods, and some suggestions or recommendations, on the lines indicated, were drawn up by medical officers of health on behalf of their sanitary authorities, there would be a general acquiescence on the part of the farmers with these recommendations.

I am, Sir, yours faithfully,

Blackburn. D. FENTON, M.B., Ch.B. Edin. D.P.H.

STERILISATION OF THE SKIN BY THE USE OF AN ALCOHOLIC SOLUTION OF IODINE.

To the Editor of THE LANCET.

SIR,—I was deeply interested in the paper by Mr. Waterhouse and Mr. Fenwick which appeared in THE LANCET of April 16th, because I have for several months employed the iodine method in *all* my operations and accidents. In the latter I have found it particularly useful, because most of the patients come with a dirty skin, and yet healing by first intention is the rule. A woodcutter came to me with a very extensive injury to his right hand produced by a circular saw, which had stripped up all the tissues of the palm of the hand, necessitating the insertion of 20 metal clips; the whole length of the cut healed by first intention. Mr. Waterhouse's note about the usual preliminary dressing is very true, and only those who have been through the process can appreciate the awful discomfort of having the skin of the abdomen thoroughly scrubbed by a nurse, then shaved (also by a nurse), and finally a wet biniodide dressing applied, covered with guttapercha tissue, and left for the long weary hours of the night before an operation. To me it was as though a million ants were crawling over the skin of my abdomen, and sleep was impossible until at 3 A.M. I got out of bed and walked round the room until the skin was thoroughly chilled, then relief came, followed by sleep. I began by using a mixture composed of two parts of lin. iod. with six parts of the tincture. This, however, produced in some patients a definite peeling of the epidermis about the seventh or eighth day, though none of them complained of any pain when it was applied. Now I am employing a solution of iodine in chloroform 15 grs. to the ounce. This has the merit of drying very quickly and not producing any dermatitis. That this method is efficacious is proved by the fact that I performed hysterectomy on a patient without shaving the pubic hairs, the extensive incision necessary healing without the slightest moisture round any of the sutures. I also operated on a patient aged 89 years, who was suffering from senile gangrene of his big toe and also from incontinence of urine, for strangulated hernia. The operation was performed two hours after I was called in to see the patient, perfect union resulting. Lastly, a patient with large pelvic cysts which required drainage was prepared by this method, and the sutures remained perfectly dry until they were removed, a very severe test. So satisfied am I of the advantages of this method of preparation that I shall never return to the old cumbersome one of a wet compress.

I am, Sir, yours faithfully,

Lincoln, April 18th, 1910. STANLEY GREEN.

AMATEUR PRINTING.

To the Editor of THE LANCET.

SIR,—Doctors are so often likely to find a field for usefulness of one kind or another in a printing press that I am surprised that more of the faculty do not take up printing, not merely as a most delightful hobby, but as a means to professional ends. The "Amateur Printers' Association" was founded by a medical man in 1895 (Dr. T. Maxwell of Woolwich) in order to popularise the craft. If any of your readers would care to have particulars of that asscciation I shall be glad to correspond with them (if only they will be good enough to enclose a stamped and addressed envelope for a reply).—I am, Sir, yours faithfully,

E. H. BLAKENEY, M.A.,
Honorary Secretary, Amateur Printers' Association.

Ely, Cambs, April 19th, 1910.

THE LATE DR. SAVILL.

To the Editor of THE LANCET.

SIR,—In view of the valuable work which has been done by the late Dr. Savill in connexion with nervous diseases, a scheme has been inaugurated, in furtherance of a wish frequently expressed by him during his life, to found a scholarship at the West End Hospital for Diseases of the Nervous System.

A considerable sum has already been received, and any further donations from professional friends and others will be gratefully accepted. Contributions should be sent addressed to Savill Memorial Fund, London County and Westminster Bank, 1, Connaught-street, Hyde Park, W.

We are, Sir, yours faithfully,

HARRY CAMPBELL
J. HENRY CHALDECOTT } Hon. Trustees to the fund.

April 19th, 1910.

THE PETROL REBATE.

To the Editor of THE LANCET.

SIR,—I should be glad to learn if any of my medical motoring brethren have applied for and obtained the rebate on the petrol tax for the period ending Dec. 31st last or for the three months since then. Personally, I have applied to the local Excise officer for the printed form which is said to have been issued, but I am met with the reply that nothing has been heard of it.—I am, Sir, yours faithfully,

April 18th, 1910. R. S. T.

*** The Finance Bill in its present form leaves untouched the abatement in this respect.—ED. L.

THE RECENT EPIDEMIC OF TYPHOID FEVER IN MONTREAL.

(FROM A CORRESPONDENT.)

NO official accounts of the epidemic of typhoid fever which commenced in Montreal and its suburbs in September of last year, and which virtually came to an end with January of this year, have been published. Nor is it likely that any correct figures showing the extent of the outbreak or the mortality-rate will be available, as owing to a variety of reasons a very large number of cases were not reported. Dr. J. E. Laberge, medical officer of health of the city of Montreal, recently read a paper on the organisation of the health department, in which he deplored the laxity of

medical practitioners in failing to report cases of different infectious and contagious diseases. He stated confidently that less than half of the infectious and contagious diseases occurring in the city were reported to the Health Department, and alluded to the fact that in one district alone in the period from Oct. 15th to Jan. 1st last the officers of the Health Department had discovered 625 cases of typhoid fever, of which only 35 had been reported. Not only in the epidemic of typhoid fever just passed, but in former outbreaks of the disease, it has been very difficult to estimate the number of typhoid cases in Montreal and its suburbs, because the law in regard to the reporting of typhoid patients has been practically ignored by medical men, and the provincial and local boards of health have acquiesced in their disregard.

The report of the Health Department on typhoid fever for the year 1909 gives the number of cases reported in the city itself and districts under its jurisdiction as 1892. In September there were reported 66 cases, in October 279 cases, in November 213 cases, and in December 704 cases. Figures obtained from the Health Department denoting the number of cases reported from Jan. 3rd to 15th are 339. Consequently the number of cases officially reported from Sept. 1st, the commencement of the epidemic, to Jan. 15th is 1601. Although the epidemic began to wane in the middle of January, and after that time died out somewhat suddenly, there was a large number of cases both reported and unreported from that time up to the middle of February, when the disease as an epidemic was to all intents and purposes over. From the middle of January to the end of the epidemic there were probably at least 200 more cases reported, which would bring up the total of reported cases to 1800. As it seems to be universally allowed that there were quite as many cases unreported as reported, a moderate estimate of the number of cases which occurred in the course of the epidemic will be 3600. The disease was most prevalent in the outskirts of Montreal. For instance, in December, in 17 wards of what may be termed Montreal proper there were 231 cases reported, while in five suburban wards there were reported in the same period 467 cases. From Jan. 3rd to 15th in Montreal there were reported 117 cases, while in six suburban wards 222 cases were reported. If population be considered, then the ratio of cases occurring in the suburbs to those in the city was nearly 4 to 1.

The difficulties in the way of arriving at an accurate presentation of the mortality-rate of the whole epidemic are insurmountable. The deaths from typhoid fever in Montreal for 1909 were, according to figures procured from the Health Department, 212. Taking the number of cases reported for 1909 as 1892, this will give a death-rate of more than 11 per cent. But if the number of reported cases be doubled, as it is believed that they should be, the death-rate will be brought down to under 6 per cent., which is by far the more likely figure. The Health Department in the statistics as to typhoid fever given from Jan. 3rd to 15th supply the number of cases and deaths. The cases reported were 339 and the deaths 41, a death-rate of between 11 and 12 per cent. The hospitals of Montreal, however, in January published the following tables. The figures cover the period from Sept. 1st to Dec. 31st:—

Hospital.	Total cases admitted.	Deaths.
General	147	9
Royal Victoria	237	9
Western	74	6
Homœopathic	80	3
Notre Dame	114	15
Hôtel Dieu	134	8
	786	50

This gives a death-rate of between 6 and 7 per cent.

In the first week of the epidemic the type of the disease was mild, but at the end of October it became far more virulent. In the Emergency Hospital, which was opened in the early part of January, 112 cases of typhoid fever were treated with 7 deaths, 2 deaths from perforation, and 1 recovery from the same, giving a death-rate of 6·25 per cent. The high death-rate at Notre Dame Hospital is attributed partly to the fact that at that institution several cases were taken in which were almost hopeless from the first.

Outbreaks of typhoid fever occur with comparative frequency in Montreal and its suburbs, a winter never passing in which there are not a very considerable number of cases of the disease. As in former outbreaks of typhoid in Montreal, there have been in the one just over numerous cases of paratyphoid and of intestinal disturbances with high fever which have led some at first to deny the existence of typhoid fever on a large scale. The lax methods in vogue in Montreal as to reporting cases of infectious and contagious disease tend to retard remedial measures.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Aberdeen University General Council: The New Medical Ordinance.

THE half-yearly meeting of the General Council of the University of Aberdeen was held on April 16th in the Mitchell Hall, Marischal College, Principal George Adam Smith presiding. At a meeting of the business committee on March 30th a subcommittee, consisting of Colonel W. Johnston, C.B., Professor John G. McKendrick, Dr. Ashley W. Mackintosh (members of the business committee), and Dr. G. M. Edmond, Dr. H. W. M. Gray, and Dr. J. Scott Riddell (members of the council, with Professor McKendrick as convener), was appointed to consider the new medical ordinance and report upon it. Dr. McKendrick submitted the report of this subcommittee. Several interesting points are dealt with in this report:—

1. *Degrees.*—The committee are of opinion that diplomas in special branches of medical and surgical practice should be conferred only on those who are graduates in medicine of the University of Aberdeen, or of any other university in the United Kingdom.

2. *Professional education (inter alia).*—(1) The committee note with satisfaction that in the case of anatomy, physiology, and pathology the distinction that has long existed between systematic and practical teaching has, in a sense, disappeared, the professor in each of these subjects having allotted to him not so much time for systematic lectures and so much for practical teaching, but so many terms to be used for the teaching of his subject at his discretion, subject, of course, to the approval of the Senatus, on the information sent to them by the boards of studies. (2) The committee recommend that "biology" should be struck out of Subsection 4 as a proposed optional substitution for "botany and zoology." (3) The committee suggest that the phrase "conduct" 20 cases of labour, although that used by the General Medical Council, is misleading and inept, and that the word "attend" is more suitable. (4) The committee also suggest that Subsection 9 relating to practical pharmacy might with advantage be omitted, and that there be substituted for it a course of such practical instruction in pharmacy during one term by the professor of materia medica and therapeutics as he may deem expedient. In these days it has become less and less necessary for a medical man in practice to be a practical pharmacist, capable of making pills, powders, and potions. These can be supplied to him in better form by highly educated chemists and druggists, and, even if he should be obliged to supply in country districts the medicine he prescribes to his patients, he can obtain these wholesale from chemists who devote themselves to this branch of trade. The time allotted in the new ordinance to practical pharmacy may, in a heavily loaded curriculum, be more profitably employed. (5) The committee point out the omission of operative surgery from the list of extra courses, and recommend that a course of one term should be devoted to it, as it has been found to be a most valuable part of surgical training.

5. *Professional examinations.*—The subcommittee draw attention to the following important powers conferred on the Senatus with approval of the University Court. They can determine (1) the interval of time that shall elapse between the time when a candidate passes the examinations in the subjects of one division and the time of his admission to examination in the subjects of a subsequent division; (2) that if a candidate fails to pass in one or more of the subjects of one division he may be prevented from attending the classes in the subjects of the subsequent division; (3) that, under prescribed conditions, a candidate may pass the examinations in the subjects of any division singly or together; and (4) that the examinations in the subjects of any division shall be taken in a prescribed order.

These arrangements will prevent students who fail in an examination from going on to other classes while they are still preparing for another examination in the subject or subjects in which they failed. Many students are severely handicapped by endeavouring to attend classes while they are preparing for an examination in subjects on which they should have passed before entering on new courses of study. The committee are of opinion that no student should pass on to the study of another group of subjects until he has passed examinations on the group immediately previous. After a reference to the times at which the various examinations may be passed, the subcommittee remark that it will thus be seen that students may, and, indeed, are expected to, pass on ten important and extensive subjects by the close of the third year of medical study. It may be questioned whether this will not prove beyond the capacity of the average student. Other two years are allowed for the final subjects. The subcommittee fear that

with such a constant stream of examinations the student would have little time to pay attention to work at hospitals, where even in his earlier years he is expected to learn the elements of clinical practice. It seems to the committee next to impossible that students can attend all these classes and pass all these examinations in the time contemplated, while on the other hand, if they do, they cannot be expected to pay sufficient attention to clinical study. The result will be that clinical study, along with attendance on the all important subjects of medicine, surgery, and midwifery, will be crushed into the final three terms, or the so-called fifth year. All clinical teachers will agree that this is far from being satisfactory—indeed, an impossible position. The committee suggest two alternatives: (*a*) that if students are to be subjected to the constant harassment of so many examinations, two terms at least should be added to the period of medical study; or (*b*) that botany, zoology, physics, and chemistry be removed from the medical curriculum, which would then begin with the subjects of anatomy and physiology. Were the latter alternative adopted there must be a preliminary scientific examination to be passed before the student begins the study of medicine, and such preliminary examination in science would be quite independent of the present preliminary examination in general knowledge. The committee favour the latter alternative.

6. *Professional examinations for degrees of M.D. and Ch.M.*—The committee do not agree with the proviso in which it is stated that under certain conditions candidates for the degrees of M.D. or Ch.M. may be exempted from the whole or part of the examination. They consider that in all cases the examinations should be thorough.

Dr. Mackintosh went over the ordinance in detail and moved that, subject to the alterations adopted by the council, the report be adopted and the recommendations sent to the University Court. Dr. W. Bruce of Dingwall seconded, and the motion was unanimously adopted.

Perthshire School Medical Inspectorship.

The Subcommittee on Secondary Education for the County of Perth has appointed as medical inspector of school children Lieutenant-Colonel Grenville E. Moffet, R.A.M.C. (retired). Colonel Moffet during his curriculum at Aberdeen held the appointment of assistant to the professors of practice of medicine and of midwifery and diseases of women and children. He also acted as senior clinical clerk to the former at the Royal Infirmary, and attended practice at the Children's Hospital under the latter. Before entering the army he acquired experience in general practice by acting as assistant and locum tenens to several men in Scotland and England. In 1893, as a surgeon-captain, he was selected by the then Director-General of the Army Medical Service for the appointment of recruiting medical officer at Glasgow, and after promotion to his present rank he voluntarily retired from the service in 1905. Since then he has been employed as medical officer in charge of the troops in the military hospital at Perth.

April 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Medical Association.

THE Council of the Irish Medical Association has adopted the report of its special committee on Poor-law reform, and the secretary has sent a copy of it to each of the members in order to take a *plébiscite* vote. In this report the establishment of a national medical service in Ireland to replace the present workhouse, county infirmary, and dispensary system, as suggested in the report of the Vice-Regal Commission, is recommended. This service would be a national medical service, entered by competitive examination, with graded salaries paid out of the Consolidated Fund and with pensions, the officers being under a board of control, which would administer the scheme. By this plan whole-time officers, wherever possible, would be appointed, and whole-time county medical officers of health with special diplomas in public health and with analytical and bacteriological experience, while only members of this national service would be eligible for appointment as medical inspectors. The authorities of the Irish Medical Association object to making the county into the unit of administration by replacing the boards of guardians, as the possibilities of promotion would be limited to each county, and the aggregate potential advantage to the members of the service would be less than if the whole service—county, Poor-law and dispensary, and public health—were coördinated as they would be in the national scheme. They point out that the recommendations might have many points of advantage in amending English Poor-law which would be unsuitable from an Irish standpoint, as the conditions in the two countries are so dissimilar. The difficulty is, and this is contained in the "Report on Ireland" by the Royal Commission on the Poor-laws, "that so long as the local rates bear the greater part of the cost of the medical service, as at present, it would be difficult to carry through Parliament a proposal depriving local authorities of any voice in the selection of their medical men;" and, further, that the Irish local authorities would "no doubt desire to retain in their hands the appointment of their medical officers" (p. 61 of Report). Again, the Royal Commissioners say (p. 62): "The Vice-Regal Commission's alternative of a service wholly charged on State funds, therefore, seems to us to be the only practicable solution of this problem, if the service is to be free from local control; but it is clear that a very strong case would have to be made out to prove the necessity for throwing this portion of the Poor-law service in Ireland wholly upon the Exchequer." The Irish Committee of the British Medical Association is also taking a *plébiscite* of the dispensary and workhouse medical officers, asking them to indicate which of these schemes (the National Medical Service as recommended by the Vice-Regal Commission, the County Medical Service as suggested by the Royal Commission on the Poor-laws, or the present system with the addition of compulsory superannuation on retirement) they prefer. When these two *plébiscites* are taken we shall be in a better position to know the mind of the medical profession in Ireland. That a national medical service would be the best solution for the medical men and also for the country is a widely held view. Such a service would command better payment and so would probably attract abler men and lead to progress in public health, which is so far behind in Ireland. But this scheme will probably be opposed by the Treasury on the ground of increased cost, and by the local authorities, who will not like to give up their present patronage.

The Queen's University of Belfast: Meeting of Convocation.

The first meeting of Convocation of the Queen's University was held on Saturday last, April 16th, Lord Shaftesbury, the Chancellor, presiding. The Examination Hall of the University, in which the members assembled, was packed to the doors. The Right Hon. Thomas Sinclair was elected chairman of Convocation, and Dr. John Campbell vice-chairman. A committee of 15 having been appointed to draw up standing orders and regulations, the chairman of convocation proposed a series of motions expressing an earnest desire for the prosperity and usefulness of the University, apart from individual views as to the merits of the general scheme of higher education in Ireland, of which it is a part. The motions also condemned any departure from the non-sectarian principles and traditions of Queen's College, Belfast, which, it was alleged, were violated by the establishment within the University of separate lectureships for the teaching of scholastic philosophy. Dr. Benjamin Moore, late dean of the Medical Faculty of the University of Liverpool and professor of bio-chemistry in Liverpool, seconded the motions. An amendment leaving out all the condemnatory portions was proposed by Rev. J. B. Armour and seconded by Professor R. B. Henry. A lively debate took place, and on a division the motions were carried by 238 to 56 votes. Dr. Moore then moved:—

That Convocation of the University desires to urge upon the Senate the need for greater development of post-graduate teaching and research and for adapting the University to the requirements of the city and district in which it is situated, for which purpose Convocation would welcome the endowment of research on a more liberal basis and free from teaching of an under-graduate type.

Mr. J. R. Fisher seconded the motion, which was carried. A notice of motion was given in by Dr. R. W. Leslie, but, at the request of the Chancellor, was held over until a future meeting of Convocation:—

That we, Convocation of the Queen's University of Belfast, emphatically protest against the prohibition imposed on the University by the Statutes against the conferring of honorary degrees in the Faculty of Medicine.

At a subsequent meeting of the Senate Sir William Whitla

was appointed representative of the University on the General Medical Council for a term of three years.

The Beri-Beri Outbreak.

Another member of the crew of the vessel *Sterling*, on which an outbreak of beri-beri took place on a voyage from Rangoon to Belfast, has died at the Belfast Union Hospital on April 17th. This is the second death amongst the crew of the ship, and there are still three ill of the malady in the Union Hospital.

The late Mr. J. G. Jefferson.

The death occurred on April 16th at his residence, Lisburn, of Mr. J. G. Jefferson, medical officer of health of Lisburn, consulting sanitary officer to the urban council, medical officer of the Lisburn dispensary district and medical attendant to the police. He was a most conscientious public officer and greatly esteemed by numerous professional and private friends. He leaves a widow and small family for whom the utmost sympathy is felt.

April 19th.

WALES.

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Port Sanitary Authority.

THE number of vessels entering the Port of Cardiff in 1909 was 11,246, compared with 12,564 in 1899. In spite of this decrease the requirements of the present day necessitate a much larger staff in the department of the medical officer of health than was the case 10 years ago, when one inspector and two assistant inspectors were deemed to be sufficient. In addition to an assistant medical officer of health there are now nine inspectors, one of whom is employed entirely in the inspection of foods. During 1909 a large quantity of unsound food was destroyed under the Unsound Food and Foreign Meat Regulations of the Local Government Board. In no single instance was it necessary to resort to legal proceedings. The total weight of the condemned foodstuffs was 1396 tons, and this included a single consignment of 1226 tons of wheat. Very little meat was destroyed under the regulations, the majority of the articles dealt with being wheat, fruit, and potatoes. In his annual report the medical officer of health (Dr. E. Walford) states that systematic inspections were made during 1909 of 8477 ships, and 933 were found to be defective. In 1899, out of 7170 ships inspected 1597 were found defective. It is satisfactory to find that the British ships were in a better condition in 1909 than the foreign. In the former defects were found in 7 per cent. compared with 23 per cent. in the latter. The bacteriological examination of samples of drinking water from vessels entering the Port of Cardiff, which has now been made for some years, was continued during 1909 at the Cardiff and County Public Health Laboratory by Dr. H. A. Schölberg, who reported upon 63 samples. In 19 instances the water was found to be good and in 27 to be distinctly contaminated.

A Poor-law Sanatorium for Merthyr.

The board of guardians of the Merthyr union has been congratulated more than once by the Poor-law inspectors of the Local Government Board upon the admirable manner in which the Poor-law institutions in the district are administered. The arrangements for the treatment of the sick have received special commendation. The Earl of Plymouth having offered the freehold of a site it is now proposed to erect a sanatorium for consumptives who are chargeable to the union. The accommodation suggested is for 50 patients —30 men and 20 women and children. There is to be a central administrative building of two storeys containing five bedrooms, and on either side a one-storey building. The central block will be constructed of stone and the remaining portion of the building of corrugated iron with a tiled roof.

Fees to Medical Practitioners under the Midwives Act.

The Hay board of guardians has decided to pay a fee of £2 to medical practitioners who are called in by a midwife under Rule 18 of the Central Midwives Board. At the meeting of the board at which this decision was arrived at the members of the board seemed to be singularly ignorant of the circumstances under which this fee might have to be paid. One member suggested that a maximum fee should be offered and that it should be left to the medical man's honour to accept a smaller sum in the event of the case being a light one, while another member suggested that the cases in which a medical man would be called in would not occur very often as midwives were now required to be qualified and would only call in a medical man when absolutely necessary. No one seemed to be aware that the conditions under which medical help must be sent for are very precisely defined by the Central Midwives Board, and that those conditions are all such as would involve anxious and very frequently tedious attendance. There is no question, therefore, as was suggested by one member, of taking the heavy work with the light, for there will be no light work.

April 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Congress of Medical Practitioners.

THE Congress of Medical Practitioners, a brief note of which was given by our Paris Correspondent in our issue of April 16th, was held at Paris from April 7th to 9th. This was the third Congress of the kind. The first was held at Paris in 1907 and gave rise to some very lively discussions. Many professors of the faculty attended and engaged in hot warfare with those members who attacked the official methods of medical teaching. The Congress resulted in the appointment of a permanent committee on which was laid the duty of studying in a more thorough manner the many very complex questions which had been inserted in the programme of the Congress. The second Congress was held at Lille and was of a more exclusively professional character. The provincial professional element prevailed and the main discussions were of a financial nature, dealing with insurance societies and benefit clubs which are in the habit of exploiting medical men. The Congress which has just concluded returned to problems of a more general and somewhat higher kind. The labours of the permanent committee have resulted in the publication of two volumes of reports containing the results of various inquiries and many tables of much interest. The following are the principal points and the resolutions which the Congress passed concerning them.

One interesting inquiry dealt with the question of the right of insured workmen and affiliated members of benefit societies to choose their own medical man when they were ill. It is well known that insurance societies and benefit societies put forward a claim to make their members be attended by a medical man appointed by the society, to whom they give a definite fixed salary. Such a medical man was prone to reduce the indemnity payable, for if he did not the society might see that he was replaced by another medical man. The syndicates of medical men undertook a very active campaign for the maintenance of the right of free choice. To this the benefit societies retorted that when free choice was allowed certain venal medical men, with a view to keeping in with the patient, used to exaggerate the gravity of his illness, the length of sick leave necessary, and the amount of the damages. Finally, the question of free choice became merged in a general war against the pretensions of the benefit societies as a whole.

The Congress having listened to an admirable report laid before it by Dr. Boillet of Lyons, adopted all its conclusions, of which the following are the most noteworthy :—

1. That the benefit societies be asked to raise the amount of their subscription, which as a rule is 5 francs, and is obviously too small to allow them to give proper remuneration to the medical man, whether he be appointed by themselves or not.

2. The Congress further demand that the law of 1898 as to benefit societies should be modified in such sort that qualification as a benefit society, and the legal advantages which such societies enjoy, should not be granted to any society which did not demand a sufficiently large subscription, which did not give equal advantages to all their members, and which did not guarantee the right of free choice, but that nevertheless a maximum fee should be agreed upon for each case.

This solution is obviously of the nature of a compromise.

Dr. Bresselle of Vésinet presented a report upon the raising of medical fees throughout France. The report showed how the returns from professional work are diminishing among all classes and in all districts. The causes of this are the exaggerated development of gratuitous advice, of various philanthropic agencies, of public lectures on medicine and hygiene, and of advertisements in the lay press of

remedies which their readers can take for themselves, to say nothing of the old grievance, of advice given by nearly every pharmaceutical chemist under the plea of urgency. The Congress decided that a committee should be appointed to draw up an appeal to the public, for insertion in the press, which should make them acquainted with, and admit the necessity for raising medical fees, a course which from certain signs would not appear to meet with any grave difficulty.

A very important paper was read by Dr. Levassort of Paris on illegal medical practice, especially as regards cases in which medical men were replaced by medical students. Dr. Lafontaine of Paris discussed the question of medical education. He wished the essential machinery of education to be in the hands of the medical syndicates, and demanded that theoretical instruction alone should be in the hands of the faculty, while the technical and practical teaching should be given in the hospitals, every pupil being at liberty to choose his own master. The office of agrégé of the faculty should be done away with, and a reform committee should be appointed, the members of which should be chosen in equal numbers from the representatives of official teaching and delegates chosen by practitioners. Dr. Le Fur wished a superior medical council organised on a similar plan to be appointed. M. Tourtourat proposed to limit the number of medical students by not allowing more students to enter each year than just sufficient to fill the vacancies really existing in the *corps médical*. M. Delpeut asked that admission to the Faculty should not be granted except by open competition. These last two propositions were referred to the watching committee for further consideration.

Dr. Léon Archambault presented a lengthy report upon the administration of hospitals at home and abroad. Among the reforms he suggested were that the direction of a hospital should always be in the hands of a medical man, assisted by an administrative colleague; that the medical officers of a hospital should form a committee to guarantee the whole direction of the institution; and that the assistant medical officers should give their whole time to the service of the patients and should live in the hospital without being allowed to take private practice. Finally, a hospital should be a real centre for the instruction of both medical men and medical students. M. Louis Regis spoke on the necessity for confining hospital benefits to the really needy, and discussed the means whereby this regulation might be carried out. M. Declercq of Lille read a careful study of the application of the law of 1902, which deals with public health. The burning question was the notification of infectious diseases, which the law says is obligatory and which brings in its train disinfection at the public expense. Medical men in general protested against this, and the whole Academy of Medicine in particular, regarding the law as a violation of professional secrecy, and one which brought them into bad odour with the family of the patient, to whom the proceedings of the municipal disinfecting staff were by no means always agreeable. It was demanded that the obligation to notify should rest with the head of the family, who should also be liable to any penalty provided for omission of this duty. M. Declercq proposed a somewhat ingenious solution of the difficulty—namely, that the head of the family should notify to the mairie, or the health department of his district, by sending in a certificate which the medical man should give him. The counterfoil of this certificate could be put in evidence to prove that it had been given to the head of the family in case he did not perform his part.

A long discussion took place as to the means for checking the very regrettable practice of procuring abortion. French law is very severe on this practice, but it is rarely put in motion. A movement has recently been started in certain medical journals to secure that the penalties for procuring abortion, whether procured by a man or a woman, should be less severe, but should be mercilessly applied. At the same time, persons of a certain cast of mind, with a very false moral code, have argued that since abortion is generally practised in modern society in conformity with Malthusian principles, and since the main danger to the mother arises from its being brought about *sub rosâ* and under defective conditions, it would be better that medical men should be allowed to bring it about openly. The Congress naturally rose against this abominable theory, and agreed that abortion, unless brought on in conformity with strict medical indications, was an absolute crime. Various resolutions on the subject were passed, among which were the following:—

1. That the number of midwives should be limited.
2. That the calling of midwife should be under the supervision of some inspection authority.
3. That any miscarriage, whether natural or otherwise, should be obliged to be notified.

On the whole it may be said that the Third Congress of Medical Practitioners was a most interesting gathering, at which both the moral and material interests of the profession were discussed fully. It is much to be regretted that the professors of the faculty, the physicians to the hospitals, and in general more official medical men did not put in an appearance, so that the debates as a whole were entirely confined to medical men engaged in practice. Consequently certain risky views put forward met with no authoritative contradictory arguments. Perhaps the chief value of the Congress lies in the two volumes of reports above mentioned, which constitute a collection of documents worthy of consultation by the medical men of all countries.

The Red Cross Societies.

In France there are three distinct Red Cross Societies—the Union of Women of France, the Association of French Ladies, and the Society for the Aid of the Wounded in War. These three societies have almost identical objects, and their original intention was admirable—namely, the training of female nurses who, in time of war, should be capable of assisting the medical officers in giving first aid to the wounded. A great number of society women of all ages have joined these societies. For many years they adhered to their original programme, but they are now seeking to enlarge the field of their activity and they attend courses of instruction on a great variety of medical subjects, the instruction being arranged for their special benefit and given by medical men. They also present themselves at special examinations, and when successful in passing they receive diplomas. Many content themselves with taking this diploma, but, on the other hand, some imagine that the possession of it entitles them to practise medicine to a certain extent. They practise at first in dispensaries established for them, where they make punctures, apply cupping-glasses, give injections of serum, and make use of a variety of surgical dressings. This amount of medical practice, however, does not suffice, and the ladies, no longer content with the dispensaries, now work in certain special hospitals. Several medical societies have naturally taken note of these proceedings and have raised protests. Some medical men (mostly those who are conducting the courses of instruction) having attempted to defend these irregularities, the question came before the general council of the Paris medical societies *d'arrondissement*. Dr. Chancel, representing the thirteenth arrondissement and speaking on behalf of his professional brethren, complained of the serious harm which the Red Cross hospitals had done to them, one of these hospitals being in their arrondissement. In the name of 50 medical men of the Société des Gobelins he joined his protest to that which Dr. Gibrie had made at a meeting of the society of the seventh arrondissement. He said that the Red Cross organisation was now following a wrong course, for the three societies had established in their hospitals advanced classes in which very complete practical instruction in every part of minor surgery was given to a multitude of ladies. This was an abuse which increased every day. Some ladies were already beginning to visit patients at home, carrying morphine and serum for the use of those who could not leave the house. These clinics were freely open, not only to necessitous patients, but to all comers. Touting for patients was carried on by asking employers of labour to send their workpeople to these hospitals and dispensaries, and similar requests were made to school-mistresses in respect of their pupils. These proceedings had resulted in an extraordinary diminution of the practice of the medical men in the thirteenth arrondissement. Some months ago the presiding officers of the society of that arrondissement paid a visit to the Hôpital des Peupliers for the purpose of explaining to the surgeon of the hospital, Dr. Cazin, that the local practitioners suffered severely in consequence of the advice given *gratis* at that institution. A request was made that such advice should be reserved for necessitous persons and that patients belonging

to the working classes should not be admitted indiscriminately, and in particular that cases of accident or injury sustained during employment should not be admitted because they were not necessitous individuals, either the employer or an insurance company being responsible for the cost of their medical treatment. Count d'Haussonville was present at the interview but could not give any definite promise with respect to the points which had been raised.

April 19th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Influence of the Sexual Glands on Bodily Development.

IN a paper read recently before the Gesellschaft der Aerzte in Vienna Professor Tandler explained the results of observations which he had made on a number of persons with a view of ascertaining the influence of the internal secretions of the sexual glands. He said that this influence was shown by direct changes in other organs, by changes in other glands possessing an internal secretion, and by changes of organs produced by secondary changes of complementary glands, an instance of the latter kind being the enlargement of the lips which sometimes occurs during pregnancy. The interstitial part of the sexual glands controlled the production of the internal secretion, which was morphologically influential. In cryptorchidism the testicle had only an interstitial part, but no generative part. A unilaterally cryptorchid horse became incapable of procreation if its healthy testicle was removed, but it nevertheless retained the characteristic aspect of a stallion. The influence of the testicle was manifested even in the embryo. Professor Tandler believed that the sex was determined *in ovo* and that the external sexual characteristics were developed under the influence of the internal secretion of the ovary or testicle. The mamma, formerly a conglomeration of sweat glands, was present in both sexes, but grew exceptionally in the female owing to the action of the ovary. The beard was formerly a character of species; it became a character of sex in the young male, but elderly females might also have a beard owing to atrophy of the ovary. When the sexual organs were hypoplastic or after castration the epiphyses remained open longer than in normally developed cases; hence the growth of the long bones. The local accumulation of fat was a secondary sexual characteristic in both sexes. In eunuchs the muscles contained fat. The hair, the nails, and the hypophysis were also under the influence of the sexual glands.

Removal of a Tumour of the Hypophysis by the Nasal Route.

Dr. Hirsch demonstrated quite recently in the same society his method of removing a tumour of the hypophysis through the nose, the patient being a woman, 35 years of age, who had suffered for seven years from continuous headache with loss of sight in both eyes. X ray examination showed a tumour of the hypophysis, and Dr. Hirsch resolved to remove it by a method which he had worked out about a year ago on the cadaver. The operation must be performed in four stages, the first of which consisted in the removal of the left middle turbinal under cocaine anæsthesia. A few days later the whole of the left ethmoidal labyrinth was removed in the same way, and after a further interval of a few days the anterior wall of the sphenoidal sinus was removed. In the above-mentioned patient all these three operations were performed within 14 days with a very small loss of blood and without pain. The operations were well known to all rhinologists. The ridge of the hypophysis, which reached low down into the sphenoidal sinus, was now well in sight, and after the administration of cocaine a special chisel was used with which the bone was carefully broken just below the hypophysis. Through the aperture a bent elevator was introduced, the bone gave way, and it could be removed piecemeal by means of bone forceps. The tumour of the hypophysis which then became visible was about half an inch long and a little less in breadth. Dr. Hirsch did not do anything more on this day, as he wished to see the effect of the decompression produced by this operation, but as after 10 days there was no improvement he again used cocaine (always in a solution of 20 per cent. strength), and by means of a fine knife the dura mater and the protruding tumour were incised. About two tablespoonfuls of a sanguinolent serous liquid thereupon gushed out, and a probe could be passed into a cavity. Part of the wall of the cavity was removed for examination, and then the nose was closed simply by means of a little sterilised cotton-wool. The entire operation was almost absolutely painless, and the effect was most gratifying. The headaches soon disappeared, and the visual power of the left eye was regained to the extent of $\frac{1}{10}$, but up to the present time (four weeks after the operation) there has been no recovery of vision in the other eye. The advantages of Dr. Hirsch's method over that of Schloffer were that general anæsthesia was unnecessary, and that the operation did not cause either pain, or loss of blood, or disfiguration of the face, or visible scars. Schloffer's method, on the other hand, required general anæsthesia for three-quarters of an hour, opening and temporary resection of the nose, enormous loss of blood, and permanent scarring of the face. The danger of meningitis was equal in both methods. In the discussion which followed this interesting demonstration Professor Chiari, Professor Eiselsberg, and Professor Hayek, who all have had large experience of the work involved in the new operation, did not raise any serious objections to it, although they were inclined to reserve their opinion as to its general advisability. The main argument against the method—namely, that it merely permitted a small resection of the hypophysis without giving a good view of the organ—could be easily done away with by improved instruments and increased experience.

Out-patients in the Vienna Hospitals and Dispensaries.

Dr. Hofmokl of the Vienna General Hospital has compiled an interesting statistical account of the out-patient departments of the hospitals and dispensaries of the city. He states that in 1908 no less than 650,000 persons were treated in the out-patient rooms of nine clinical wards, three private hospitals, and three children's hospitals. This is equal to 30 per cent. of the entire population of the city. During the same time 100,000 persons were admitted as in-patients. It is worthy of note that in the clinical departments there were only 350,000 out-patients, whilst in the remaining institutions there were 300,000, inclusive of 122,000 children up to the age of 14 years. The prevalence of hospital abuse is well illustrated by the fact that more than 500,000 of the patients belonged to sick clubs or other similar associations. The law now makes insurance against sickness compulsory for the majority of the working classes, and in order to save trouble the club medical officers very often advise their patients to make application to the hospitals. The patients get their sick pay and obtain treatment in the hospitals even as out-patients, for in our hospitals there is no supervision or inquiry as to the income or social position of the persons seeking advice and treatment, and various attempts which have been made to introduce a better system have proved futile. If it could be arranged that the hospitals should admit only necessitous persons the expenditure of these institutions would be reduced, while on the other hand the sick clubs would have to increase the number of their medical officers and to remunerate them better.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

Important Change in Medical Education.

THE University of Pennsylvania, whose medical school is the most ancient in this country, has just made a move of a most important character in regard to medical education, which is to come into force with the next academic year. While the strictly scientific and laboratory sides of medical education have progressed to a leading position in America, owing to the prompt realisation of the fact, by a people renowned for practicality, that the exacting nature of such studies and research is incompatible with the demands of private practice and the consequent endowment of research and laboratory specialists, the clinical branches of medical teaching and research have continued in much the same routine and with much the same methods as were in vogue a century ago. The awakening has, however, at last occurred to the fact that the clinical medicine of to-day also has changed, and that its wider reach, its more complex

methods, its more intimate association with the sciences of precision demand that the more important chairs, at least, in this division also, should command the whole, or almost the whole, time of their incumbents for teaching and research. As experts, perhaps, it might be for the public good, and even that of medical science itself, that they should be allowed to give the benefit of their special medical scholarship and erudition in consultation; but that they should be burdened with the strain and the thousand exactions of active practice has at last been recognised as incompatible with a progress in the clinical branches of medicine comparable with the strides made in laboratory medicine. In future, therefore, the chairs of medicine, pathology, and pharmacology are to be placed on this basis, while new departments are announced for physiological chemistry, comparative pathology, and research medicine. The appointments are to be as follows: Medicine, Dr. David L. Edsall (Dr. James Tyson retires after very many years of most honourable record), assisted by Dr. J. H. Musser and Dr. Alfred Stengel; pathology, Dr. Howard F. Ricketts, from the University of Chicago; physiological chemistry, Dr. Alonzo E. Taylor, from the University of California; comparative pathology, Dr. Allen J. Smith; research medicine, Dr. Richard M. Pearce, from University and Bellevue Hospital Medical College, New York. The chair of pharmacology has not yet been filled. Another important item in the programme of reconstruction is the division into three departments—social, laboratory, and clinical—of the associated Henry Phipps Institute for the Study of Tuberculosis, which will thus afford ample opportunities for clinical teaching as well as for research work in this modern cynosure of medicine. It is gratifying to learn that very generous provision has been made to support these changes. It is earnestly to be hoped that possible munificent donors of the future will follow the lead thus set and emancipate many other medical schools throughout the country from their present thraldom to the antiquated conditions of pioneer civilisation.

The Banquet to Dr. W. H. Welch.

The banquet given to Dr. W. H. Welch, professor of pathology at the Johns Hopkins University, at Baltimore on April 2nd will long stand out as a mark in the annals of American medicine, for it had a professional as well as a personal significance. Dr. Welch is perhaps better known than any other American physician to the British profession in general, if for no other reason, at least as the deliverer a few years ago of the Huxley lectures on Immunity. On this continent he stands as the acknowledged leader of the profession, and the wonder is, not that he should have been tendered a banquet, at which some 450 men and women, representative not only of the medical sciences but of science and learning in general, of industry, commerce, and politics, were present, but that he should for so long have succeeded in his persistent efforts to evade that honour. The fact that Dr. Welch is president-elect of the American Medical Association, however, was too good an occasion to let slip, and he has been fairly "corralled" into at last assenting to what he had so often refused. The honour in this case is not merely a degree *honoris causâ*, but one granted *summâ cum laude* for work done, a degree specifically earned by his constant unremitting faithful labours on behalf of the association as a member of its board of trustees. The banquet was a triumph and I make no attempt to give any detailed account of it. Suffice it to say, that many speeches were delivered—eulogistic by Dr. W. S. Thayer, who acted as toastmaster, humorous by Dr. Abraham Jacobi, poetic by Dr. Weir Mitchell, in various veins by others; but through them one and all ran the same refrain—admiration, devotion, affection. All emphasised the leadership attained by Dr. Welch among medical scientists, teachers, university administrators, and national councillors. And his work is still going on, and will continue to go on even long beyond his own personal career, through an apostolical succession of pupils, who even now hold a large proportion of the important posts that medicine, and particularly pathology, has to offer in the United States.

Legislative Control of the Cold Storage of Foods.

The public interest in the practice of wholesale dealers in foods, who collect immense quantities of perishable foods in cold-storage buildings and thus create a scarcity of such articles in the markets and a consequent increase of the prices of such articles, has culminated in the effort in many States to place these establishments under rigid Governmental control. When the cold-storage system was first undertaken there was a general belief that it would tend to meet the emergencies which often occurred through great scarcity in foods by having an ample supply on hand. It was also believed that this supply, ready at any moment to be delivered to the retail dealers, would prevent any increase in the prices of food when there was a diminished supply, as usually occurs in the changing of the seasons. But the contrary has proved to be true. By means of cold storage the wholesale dealer has been able to make a scarcity of the food in which he is interested at any time and to raise the price of the food at his will. We have just passed through such an experience. Eggs, for instance, almost disappeared from the market by concerted action of the large dealers, and yet thousands of dozens were in storage near at hand and were supplied at prices prohibitive to the masses of the people. The methods of remedying this growing evil are numerous, but all aim to place such restrictions upon the storage of foods and to provide such governmental oversight of these establishments as will prevent the abuses which have now become intolerable.

Summary of the Antituberculosis Campaign.

A review of the work done in the campaign against tuberculosis has been published which shows the following facts: In the year 1909 $8,180,621 were spent, 9,456,409 pieces of literature were distributed, and 117,312 patients were treated. There were about 300 associations engaged in the work and the capacity of the various institutions aggregated 14,208 beds, 60 per cent. being for incipient cases, 15 per cent. for moderately advanced cases, and 25 per cent. for advanced cases. The demand for institutional care is increasing and the small local hospital is becoming popular. The average daily individual expenditure of hospital and sanatoriums was $1.34. There are 250 dispensaries with 61,000 patients. Reports from all parts of the country indicate that during the present year the work will be more than doubled. Special antituberculosis appropriations, aggregating $3,976,500, have been made in the various municipalities this year, and in addition over $4,000,000 have been appropriated by State legislatures. Large numbers of new organisations are being formed and existing institutions are planning enlargement of their operations.

Medical Men as Expert Witnesses.

Mr. William Travers Jerome, ex-district attorney of New York city, recently advocated the establishment of a tribunal for the medical profession which should have power to suspend or expel members of the medical profession for gross professional misconduct, as lawyers are disbarred under corresponding circumstances. Mr. Jerome, however, seized the opportunity to say some very comforting things about the general sincerity of medical men, in view of the widespread denunciation and impugning of the profession in respect of their alleged venality as expert witnesses. "No man," he said, "has had more experience with experts than myself during the eight years I was district attorney, and during that time I recall only one man whose testimony was radically dishonest. There were many who disagreed with me honestly." And again, in speaking of one medico-legal case in which there was a miscarriage of justice with consequent scandals, he said: "I am positive in stating that the scandals arose through judicial incompetency rather than from any corrupt medical testimony."

April 12th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE plague returns for the week ending March 12th show 20,928 deaths, compared with 21,514 in the week preceding. The Bombay Presidency reported 1005, Bengal 3076, the United Provinces 8792, the Punjab 6502, Burma 303, and the Central Provinces 1095. The Central India and Rajputana returns have not yet been received. Mr. A. C. Walker, I.C.S., District Magistrate of Mainpuri, presided over a mass meeting of the citizens of Mainpuri which was called by Munshi Prem Behari, sub-judge and secretary of the Plague

Committee, to consider measures for the prevention of plague, on March 9th, at the Aikman Union Club. Captain H. B. Steen, I.M.S., civil surgeon, explained that the rat was the chief cause of plague, and therefore the houses should be kept free of them by using rat poisons, burning sulphur or naphthaline balls, and keeping cats. Captain Steen gave many other useful hints on the subject. Chaube Dammilal said he addressed the meeting as a non-official, and pointed out that in Hindu religion self-preservation was more important than the killing of animals, and there was no valid religious objection to killing rats. Maulvi Fazi Karim and Mr. Prem Behari also delivered addresses on the subject, and Mr. Asgar Hussain explained the havoc created by the plague and described the remedies.

A School of Tropical Medicine for India.

In connexion with the proposal to establish a Pasteur Institute in Assam, public interest has been quickened in the more important question of a School of Tropical Medicine for India. The subcommittee of local medical men which reported on the proposed institute urged that original research into such diseases as kala-azar, blackwater fever, &c., could be carried out with great advantage in Assam. But if India is to have its tropical school, and it certainly should have, something more must be done than the creation of an annexe to the small Pasteur Institute at Haflong. The time has come when the Government should move in the matter and no longer entirely rely upon the London and Liverpool schools for post-graduate instruction for medical officers. In no country is the necessity for a tropical school of medicine more urgent than it is in India, and the endowment of such an institution should no longer be delayed. Calcutta would seem to be the place indicated, and the school should be founded in connexion with the Medical College, where the opportunities for clinical study are unrivalled. The Government of India is being appealed to constantly for more grants for sanitation, the prevention of malaria, &c., but if there are spare funds available some portion of them could well be diverted to the scientific school, for which there is now so clear a demand. The question is one which claims immediate attention, and this it will doubtless receive at the hands of the responsible medical authorities.

Hospital Assistants.

The Government of India has approved of the effective strength of the hospital assistant branch of the Indian Subordinate Medical Service being revised as follows: Total 873, of which Bengal will have 579, Madras 110, and Bombay 184.

The Civil Medical Profession in India.

At a meeting of the Imperial Legislative Council held at Calcutta on March 18th, His Excellency the Viceroy presiding, Mr. Gokhale asked for information respecting the steps taken or in contemplation to give effect to the recommendations contained in Lord Morley's despatches on the subject of the growth of a civil medical department in India. Replying to Mr. Gokhale, Sir Harvey Adamson said:—

The Government are aware that there is a desire on the part of medical practitioners in India to be admitted to Government medical appointments, but they are not aware that any considerable dissatisfaction exists in the country on the subject. At present the chief civil surgeoncies, the hospital appointments, and the teaching appointments in the Government medical colleges are mainly held by officers of the Indian Medical Service. The Government are, however, considering the possibility of throwing open a certain number of such appointments to non-official medical men. The honourable Member is not correct in suggesting that the Secretary of State has recommended the establishment of a civil medical department in India. It was decided by Lord Morley that the time had arrived when no further increase of the civil side of the Indian Medical Service should be allowed and that efforts should be made to reduce it by gradually extending the employment of civil medical practitioners recruited in India. Effect has been given to the first portion of that decision, and, as already stated, the Government are considering what steps can be taken to give effect to the second of these principles. Local governments have been addressed on the subject, but until their replies have been received and considered, the Government are unable to state what form the decision will finally take.

The New Hospital at Coonoor.

Matters appear to be maturing satisfactorily for the construction of the new hospital at Coonoor under the auspices of Major R. Bryson, I.M.S., the present medical officer of that sanatorium. Major Bryson's tenure of office terminates in the course of a few months, and great regret is expressed locally at the prospect of losing so popular an officer, who wished to see the new institution started before he leaves. The reputation of the existing hospital, cramped and unsatisfactory as its accommodation is, is so good that the sick are flocking to it from all parts of the district. An excellent chief had the desired effect of producing an attentive and competent staff, one of the most useful of whom is the native assistant surgeon, Mr. Menon, who hails from the Western Coast and is an efficient assistant to Major Bryson. The proposed new hospital will provide a European block to comprise four wards, each containing one bed; a native male ward, containing nine medical and five surgical beds; a native female ward, containing six medical and four surgical beds; a maternity ward, containing four beds, connected by a passage with a labour ward; and an out-door patient dispensary. The plans and estimates for the institution, thus equipped, will no doubt be accepted and financially provided for, when construction will be put in hand.

March 26th.

Obituary.

FREDERICK WILLIAM JORDAN, M.D. DURH., L.R.C.P. LOND., M.R.C.S. ENG., B.SC. VICT., D.P.H.

MANCHESTER and the district round it has recently lost a well-known member of the medical profession in the person of Dr. F. W. Jordan of Heaton-Chapel, near Stockport, who died suddenly at Blackpool, where he had gone on a visit to recruit his failing health. Dr. Jordan received his medical education at Owens College, and qualified in 1873 as a Licentiate of the Royal College of Physicians of London, a Member of the Royal College of Surgeons of England, and a Licentiate of the Society of Apothecaries. For some time he was an assistant house surgeon at the Sheffield General Infirmary. In 1889 he took the public health diploma at the Owens College, and in 1897 became a Doctor of Medicine at the University of Durham, and seven years later, in 1904, he took the B.Sc. at the Victoria University of Manchester, and was also a Radcliffe student at Oxford. For 15 years he acted as medical officer of health for the Heaton Norris district, and on the completion of this period he was presented by the members of the Heaton Norris council with an illuminated address of congratulation.

Outside his professional work Dr. Jordan was keenly interested in meteorology, and for a long series of years kept careful records which he often contributed to the local press. He was also a Freemason, and the esteem in which he was held within that body was shown by the offices which he had filled. His chief literary work was a life of his uncle, Mr. Joseph Jordan, well known at one time as an honorary surgeon to the Manchester Royal Infirmary. The "Life of Joseph Jordan" contained a history of the medical schools of Manchester and many details of provincial medical education which will some day be of considerable interest. Among the papers which he contributed to various medical journals were "Notes on Diphtheria" in the *Practitioner*, 1884, "A Chapter on Sanitary Jurisprudence" in *Public Health*, 1889, and "Infective Sore Throat or Diphtheria?" in the same publication in 1894. The funeral took place at the Manchester Crematorium after a memorial service at St. Paul's Church, Heaton Moor.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. H. Kuborn, formerly president of the Royal Belgian Academy of Medicine.—Dr. Paul Moinard, formerly physician to the Paris hospitals.—Dr. Max Hirschberg, one of the most eminent surgeons in Frankfort, died suddenly from heart disease in a cab as he was returning from the Surgical Congress. He was 67 years of age and had written a good many papers on surgical subjects, especially dealing with abdominal operations.

LITERARY INTELLIGENCE.—Messrs. Constable and Co. are publishing immediately a valuable little book of pocket size, being a Guide to the Preservation of Health in West Africa, by Henry Strachan, F.L.S., C.M.G., &c., principal medical officer in Southern Nigeria. Mr. Strachan's work is so well known that this booklet should be welcomed by all whose avocations carry them to this district, where the care of health on certain definite lines is necessary.

Medical News.

UNIVERSITY OF LIVERPOOL.—The following is a list of the successful candidates in the recent examinations for the Diploma in Tropical Medicine:—

Richard Dowden, M.D. Dub.; William Robert Wallace James, L.R.C.P. & S. Edin., L.F.P.S. Glasg.; Vishnu Tatyaji Korke, M.R.C.P. Edin., L.M. & S. Bombay; John William Scott Macfie, M.B., Ch.B. Edin.; Mack Walter Manuk, M.B., C.M. Edin.; Kishavlal Balabhai Nanavati, L.M. & S. Bombay; Ralph Welty Nauss, M.D. Chicago; Thiruchelvam Sabastian, L.R.C.P. & S. Edin., L.F.P.S. Glasg., M.D. Brux.; Hugh Thomas Shaw, M.D., M.Ch. R.U.I., D.P.H. Liverp.; Antonio Bernardo de Souza, L.M. & S. Bombay; and Captain Maurice Forbes White, I.M.S., M.B., Ch.B. Aberd.

UNIVERSITY OF GLASGOW.—The following have passed the first professional examination for the degrees of M.B., Ch.B. in the subjects indicated (B., Botany; Z., Zoology; P., Physics; and C., Chemistry):—

George Kirkwood Allan (Z. and C.), Jas. Mair Anderson (P. and C.), Robert Armstrong (Z. and C.), George Flett Barr (Z. and C.), Andrew Duffield Blakely (C.), Abraham Blashky (Z.), Robert William Brander (Z.* and C.), William Hunter Brown (Z. and C.), William Edmund Alexander Buchanan (Z. and C.), James Wilson Burton (P.), James Campbell (Z. and C.), John Campbell (B. and P.), James Alexander Chrystie (C.), Allan La Barte Clark (B. and P.), Andrew Climie (Z. and C.), George Gibson Cooper (P. and C.), James Paterson Crawford (Z.), William Cullen (B. and P.), Walter Thompson Currie (Z. and C.), Fritz Vivian Daeblitz (B. and C.), Gabriel Daniel de Kock (B. and P.), Michael Devers (P.), Thomas Ingram Dun (B. and C.), Dugald Ferguson (Z.), James Bryan Fotheringham (C.), William Gibson (Z.), Thomas Gilchrist, M.A. (B., Z., and C.), John Aitken Gilfillan (Z. and C.*), Peter Gordon (Z. and C.), Robert Masson Greig (Z. and C.), Alexander Hislop Hall (Z. and C.), Eduardo Guillermo Sanchez Hall (B. and P.), David Cochrane Hanson (Z.), David Hardie (Z.), Fergus Leslie Henderson (Z. and C.), Rollo Isbister (Z.), William Yuill Jamieson (B., P., and C.), Alastair Caulfield Jebb (Z. and C.), David Johnston (Z. and C.*), Douglas Reid King (B.), William Fulton Kivlichan, M.A. (Z.), Hugh Lang (Z. and C.), Alexander Lindsay (B.), Reginald Lyon (B. and P.), Douglas M'Alpine (B.), Daniel Steel M'Bean (Z. and C.), George M'Callum (Z. and C.), Archibald Munn M'Cutcheon (Z. and C.*), Duncan Fraser Macdonald (Z. and C.), James Walter Macdonald (Z. and C.), John Bowes M'Dougall (Z.* and C.*), Gerald James M'Gorty (Z. and C.), Charles Robertson M'Intosh, M.A. (Z. and C.*), Donald M'Intyre (Z. and C.), Donald M'Donald M'Intyre (B., P., and C.), James Murdoch Mackay (Z. and C.), David Mackie (B. and Z.), Philip Stevenson Mackie, M.A. (Z. and C.), Neil MacLeod (B.), Frederick William M'Millan (Z. and C.), Robert M. M'Minn (B. and C.), David M'Neill (Z.), Jas. Kennedy Manson (B. and P.), William Martin (Z. and P.), William Moffat Matthew (Z.), Walter John May (Z.), William Meikle (Z. and C.), Alexander Dryden Moffat (Z. and C.*), James William Moffatt (Z. and C.*), Thomas Fraser Noble (B.), Thomas Augustine O'Brien (C.), James Paterson (Z. and C.), William Luddington Peacock (Z. and C.*), Andrew Picken (Z. and C.), John Stuart Prentice (Z.), Frederick Powlett Rankin (Z. and P.), Adam Rankine (P.), Robert Cecil Robertson (Z. and C.), Stanley Robertson (Z. and C.), Stuart Robertson (Z. and C.), Stuart Dewar Robertson (Z.), George William Ronaldson (B. and C.), Robert Rowan (Z. and C.), Alexander Scott (Z. and C.), James Reid Sinclair (Z. and C.), Norman M'Gaan Smith (Z. and C.), John Banks Steven (Z. and C.), John Symington Stewart (B., Z., P., and C.), Robert Tennent (Z.* and C.), Cecil Raymond Tytler Thompson (C.), Robert Mitchell Thomson (Z. and P.), Robert Noel Thomson (Z.), James Vallance (Z. and C.), Carel Johannes van Lingen (B.), James Walker (Z. and P.), Robert Bruce Wallace (B. and P), Henry Currie Watson (Z., P., and C.), John Allan White (B. and P.), Clive Alan Whittingham (Z. and C.*), Joseph Bannister Williamson (Z.* and C.*), Robert Horatio Williamson (C.), James Gordon Wilson (B. and Z.), Thomas Robert Wilson (P.), John Wylie (Z. and C.), Thomas Wilson Wylie (Z. and C.), Alexander Young (B., Z., and P.), and John Miller Young (B. and P.).

Women.—Dagmar Florence Curjel (Z. and C.), Muriel May Curtis (P.), Ethel Winifred Gompertz (Z. and C.), Lillias Beverley Hardie (B., P., and C.), Florence Scott Kirk (Z. and C.), Gladys Montgomery (Z.* and C.), Janey Lamond Munro (Z. and C.), Sara Adam Watson (Z.* and C.), Grace Birrell Whish (Z. and C.), Marguerite Wilson (Z. and C.), and Mary Ferguson Wood (C.).

* Passed with distinction.

The following have passed the second professional examination for the degrees of M.B., Ch.B., in the subjects indicated (A., Anatomy; P., Physiology; M., Materia Medica and Therapeutics):—

William Larmour Anderson (P.), James Angus (A.), Richard Archibald Barlow (A.* and P.*), Johannes Gerhardus Becker (A., P., and M.), Samuel Blumenfeld (A., P., and M.), Vynne Borland (A.), Adam Brown (A., P., and M.), Robert Archibald Brown (P.), William Brown (P. and M.), John Scouler Buchanan (A., P., and M.), William Murdoch Buchanan (M.), Edmund Tytler Burke (P.), John Joseph Burke (P. and M.), John Cameron (P.), Norman Cameron (P.), William Leonard Cassells (A. and P.), James Alphonsus Joseph Conway (A. and P.), Robert Craig, M.A. (A. and P.), Daniel Augustine Cush (P.), George Dalziel (A. and P.), Alexander Hugh Davidson (P. and M.), William Cameron Davidson (A. and P.*), William Tennent Gairdner Davidson (A., P., and M.), James Henry Dible (A. and P.), John Dickie (A.,* P.,* and M.), William Beatson Drummond (A., P., and M.*), Robert Findlay (A.), John Maitland Forsyth (P.), William Forsyth (A., P., and M.), John Erskine Fyfe (A., P., and M.), Adolph Robert Hanns Geyer (A.), John Joseph Gibb (A., P., and M.), Alexander Muir Gibson (A., P., and M.), Alexander Glen (A., P., and M.), Leopold Glushak (P.), James M'Farlane Grier, M.A. (P. and M.), John Alexander Harper, M.A. (A., P., and M.), Daniel Christopher Hayes (A., P., and M.), John Wishart Welsh Hewitt (P. and M.), Andries Johannes Joubert (A., P., and M.), Felix Arthur Kerr (M.), Charles Joseph Kirk (P.), Robert Patrick Archibald Kirkland (A., P., and M.), Johannes Arnoldus Kruger (A. and P.), Norman Veitch Lothian, B.Sc. (M.), Crawford Lundie (A. and P.), Jas. Ronald M'Curdie (P. and M.), Charles Aloysius M'Guire (A., P., and M.), Guy Dalzell M'Lean (A., P., and M.), John Malcolm Macpherson (A., P., and M.), John Henry Magoveny (P.), Malcolm Manson, M.A. (M.), Thomas Martin (A., P., and M.), John Mitchell (A.), William Montgomery (P. and M.), Michael Murphy (P. and M.), Hugh Loudon Neil (M.), John Boyd Orr, M.A. (A. and P.), Robert Parker (M.), Andrew Peden (P.), John Clark Pyper (A., P., and M.), James Francis Quigley (Lambhill) (M.), David William Reid (A. and P.), John Ritchie Richmond Ritchie (A. and P.), Alfred Leopold Robertson (A. and P.), James Gordon M'Gregor Robertson (P.), James Hinton Robertson (A.* and P.), James Inglis Robertson (A., P., and M.), Archibald Watson Russell (A. and P.), Samuel Rutherford (A., P., and M.), Frank Shearar (P. and M.), John Finlayson M'Gill Sloan (P. and M.), James Smith (A.), Alexander Robert Bogue Soga (A., P., and M.), Malcolm Sommerville (A.), Graham Stevenson (A., P., and M.), John Alexander Stewart (A. and M.), Ronald Stewart (A., P., and M.), William Patrick Andrews Stewart (P. and M.), William Taylor (A. and P.), William Rowland Taylor (A. and P.), John Cameron Thomson Teggart (A., P., and M.), Ernest Graham Young Thom, M.A. (A. and P.), Angus Walker (A.* and P.), John Cuthbertson Walker (A.), Thomas Walmsley (A. and P.*), Tom Waterhouse (A. and M.), George Milroy Whish (A., P., and M.), Matthew White, M.A. (A. and P.), William Herbert Nairne White (P.), William Whitelaw (A., P., and M.), William Brockie Wilson (A.,* P.,* and M.), William Ferguson Wood (P.), and Walter Percy Yates (A., P., and M.).

Women.—Cecilia Small Turnbull Anderson (P.), Jane Malcolm Davidson (A. and P.), Maggie Logan Kirkwood (A. and P.), Barbara Macgregor (M.), Helen Brown Orr (M.), Lucy MacBean Ross (M.), Isabel Jane Stark (M.), Petrina Stewart (P.), and Janet Morris Walker (A.).

* Passed with distinction.

The following have passed the third professional examination for the degrees of M.B., Ch.B., in the subjects indicated (P., Pathology; M., Medical Jurisprudence and Public Health):—

James Wallace Anderson (P. and M.*), Charles Averill (P. and M.*), Thomas Stewart Barrie (P. and M.), William Egon Halman Beard (P.), John Bower (M.), Charles Brash (M.), David Sands Brough (P. and M.), Alexander Hogg Brown (M.), James Turner Brown (P. and M.*), Angus Dugald Buchanan (M.), Charles Cameron, M.A. (P.* and M.*), John Campbell (P. and M.), Robert Corbett Corbett (P. and M.), Peter Drummond (P.), Alexander Moffat Dunlop (M.), Kinloch Falconer (P. and M.), James Findlay, M.A. (P.), Hugh Forrest (P. and M.), Alexander Fraser (P. and M.), Thomas Lochhead Fraser (P.), Leander Lowrie Fyfe (P. and M.), Archibald Gardner (P. and M.), Andrew Garvie (P. and M.), John Gibson, M.A. (P.* and M.), William Gordon Goudie (P. and M.), John Radcliffe Grice, M.A. (P. and M.), Charles Hope Haddow (P.), James Stewart Hall (P. and M.), Andrew Smith Hannay (P.), James Hendry, M.A., B.Sc. (P. and M.), John Richmond Herbertson (P. and M.), James Johnstone (P.), William Johnstone (P. and M.), Thomas Joseph Kirk (P.), Alexander Kirkhope (P.), John M'Callum Lang (P. and M.), Norman M'Farlane (P. and M.), James David Mackinnon (P. and M.), Murdo Mackinnon (P.), William MacMurray (P. and M.), William Wyllie MacNaught (P. and M.), Stephen Anderson MacPhee (M.), George Hanson M'Robert (M.), John Pearson M'Vey (P. and M.), Malcolm Manson, M.A. (P. and M.), Frank William Martin (P.), Farquhar Matheson (P. and M.), James Matheson (P. and M.), Donald Meek (M.), Stuart Spence Meighan, B.Sc. (P.), Andrew Muir (P. and M.), Michael John Murray (M.), Archibald Naismith (M.), Hugh Loudon Neil (P. and M.), Hugh Paterson (P. and M.), James Francis Quigley (Rutherglen) (P. and M.*), Alexander Rae (P.), Hugh Young Riddell (M.), John Livingstone Scott (P.), William Logan Scott (P.), John Ferguson Smith, M.A. (P. and M.), William Sneddon (P. and M.), Roderick Alexander Steven (P.), Lawrence Tweedie Stewart (P.), James Alexander Hamilton Telfer (P. and M.), William Tudhope (P.), Gordon Alexander Valentine (P. and M.), Alexander Gold Waddell (P. and M.), James Douglas Walker (P. and M.), Alexander Guthrie Semple Wallace (M.), Hugh Ferguson Watson, L.R.C.P. (P.*); Alexander Stewart Wilson (P. and M.), Douglas Wilson (P.), High Gilmer Wilson (M.), and Fergus Hay Young, M.A. (P. and M.).

Women.—Agnes Barr Auchencloss (P. and M.), Marie Alexina Annette Beard (M.), Louisa Emma Dodge (M.), Isabel Inglis (M.), Jeanie Walker Jones (P. and M.), Katherine Stewart Macphail (P. and M.), Barbara Grace Rutherfurd (P. and M.), and Barbara Sutherland, M.A. (P. and M.).

* Passed with distinction.

The following have passed the fourth (final) professional examination for the degrees of M.B., Ch.B.:—

Thomas Adam, M.A., M.R.C.S., David Rutherford Adams, Archibald Aitchison, Charles Auld, John Bruce Baird, B.Sc., Edgar Barnes, M.A., Charles Stewart Black, John Broadfoot, William George Clark, James Thomson Dick, James Dunlop, M.A., Robert Gilchrist, Pietro Giuliani, Allan Byars Hamilton, Saul Hyman Harris, James Walker Jones, Honoria Somerville Keer, Angus Macaulay, Ian Macdonald, Malcolm Angus MacDonald, Donald M'Dougall, William Macewen, William Maxwell M'Kie, Thomas Mackinlay, Donald Mackinnon, Agnes Mary M'Michael, Angus Millar, Margaret Muir, Mary Amelia Pilliet, Olive Robertson, Joseph Henri Napoleon Felix Savy, James M'Alpine Scott, M.A., John MacNaught Scott, M.A., William Wilkie Scott, George Rae

Spence, Edward Ernest Stewart, Andrew Edgar Struthers, B.Sc., Charles Lindsay Sutherland, Duncan Macnab Taylor, Aidan Gordon Wemyss Thomson, Jemima Wallace, William Samuel Waterhouse, Harold Edward Whittingham, William Richard Wiseman, M.A., B.Sc., Marian Aitken Wylie, M.A., and Douglas Young.

The following passed with distinction in the subjects indicated:—

In (*a*) Surgery and Clinical Surgery, (*b*) Midwifery—William Macewen. In Surgery and Clinical Surgery—Malcolm Angus MacDonald. In Practice of Medicine and Clinical Medicine—Jas. Thomson Dick, James Dunlop, M.A., and Harold Edward Whittingham. In Midwifery—David Rutherford Adams and John Broadfoot.

QUEEN'S UNIVERSITY, BELFAST.—At examinations held recently the following candidates were successful:—

FIRST MEDICAL EXAMINATION.

Botany.—A. E. M. Carleton, Vincent Magee, and V. C. Montgomery.

Zoology.—R. G. Blair, F. J. Devlin, Edmund Doherty, John Duffin, A. Fullerton, Margaret Gorman, Thomas Grimson, W. H. Hardy, W. S. B. Hay, Beattie Lyons, Walter T. McCurry, A. G. McKee, T. B. McKee, Frederick McKibbin, R. N. McKinstry, Terence P. McQuaid, Vincent Magee, R. J. Maguire, E. A. Mallon, Sylvia Marsh, V. C. Montgomery, W. N. Montgomery, J. J. Murray, G. W. Rea, E. M. Robb, J. C. Robb, J. S. Savage, A. F. L. Shields, F. A. E. Silcock, F. G. Smyth, J. Tate, R. F. Walker, and Peter P. Wright.

Experimental Physics.—R. G. Blair. Wm. M'N. Chesney, W. W. Dickson, Edmund Doherty, John Duffin, A. Fullerton, David Gaston, W. S. Gibson, Thomas Grimson, W. H. Hardy, Charles C. Humphreys, Frank Lamont, Beattie Lyons, W. T. McCurry, James McKay, Fredk. McKibbin, R. N. McKinstry, H. F. McNally, T. P. McQuaid, R. J. Maguire, E. A. Mallon, G. R. B. Purce, G. W. Rea, J. C. Robb, W. Russell, J. S. Savage, A. F. L. Shields, F. A. E. Silcock, F. G. Smyth, A. C. Taggart, J. Tate, D. B. L. Walker, R. F. Walker, D. K. Watterson, R. H. Wilson, W. R. E. Wilson, and Peter P. Wright.

Chemistry.—A. W. Bourke, A. E. M. Carleton, W. J. Carson, H. T. Chatfield, W. M'N. Chesney, Robert Condy, W. W. Dickson, S. J. W. Donald, David Gaston, Michael Gilligan, George Gordon, Charles C. Humphreys, J. F. D. Hunter, D. Jamison, L. Jefferson, W. J. Lascelles, James McKay, H. F. McNally, Vincent Magee, V. C. Montgomery, M. G. Paul, G. R. B. Purce, F. R. Sinclair, J. M. Smith, James Smyth, J. K. Stewart, D. B. L. Walker, J. C. Wilson, R. H. Wilson, W. R. E. Wilson, F. N. Woods, and Robert Woodside.

SECOND MEDICAL EXAMINATION (*Old Regulations*).

Practical Chemistry.—A. M. Berman, H. Buchanan, J. E. Finlay, Wm. Gault, H. D. Graves, S. A. Montgomery, D. K. Patterson, and D. Stevenson.

SECOND MEDICAL EXAMINATION (*New Regulations*).

Samuel Acheson, *S. R. Armstrong, *S. H. Davison, J. McI. Gibson, Fredk. Jefferson, John McFadden, Michael McGing, Edward McSorley, Ivan W. Magill, H. H. Mulholland, *W. M'N. Walker, Harold V. Walsh, J. R. Henry, and Joseph Porter.

* Passed with honours and prize awarded.

THIRD MEDICAL EXAMINATION (*Old Regulations*).

W. F. Algeo, W. W. Allison, *J. H. Beverland, David Calwell, Miss S. B. Calwell, C. L. Gaussen, N. C. Graham, J. J. Hanratty, James Hill, J. T. Kyle, James Lyons, A. L. McCreery, Richard McCulloch, †Robert Marshall, William Megaw, A. E. H. Reid, S. I. Turkington, and S. J. Yeates.

Materia Medica.—H. A. Gillespie and G. E. Hull.

* Passed with honours and gained first scholarship.

† Passed with honours and gained second scholarship.

M.B., B.CH., B.A.O. DEGREES.

J. B. Crawford, C. H. Harbinson, J. H. Harbison, *J. L. Jackson, Barkley McCullough, Hamilton Mathewson, G. E. A. Mitchell, K. F. Mulligan, John Spence, †W. W. D. Thomson, and A. W. Connolly.

* Passed with second-class honours.

† Passed with first-class honours and awarded scholarship (£40).

Pathology, Medical Jurisprudence, and Hygiene.—Samuel Campbell, S. K. McKee, T. J. Magill, and A. H. Rentoul.

Hygiene and Medical Jurisprudence.—Elliot P. Dewar.

HOSPITAL SATURDAY FUND.—The annual meeting of this Fund was held on Saturday last, April 16th, at the Mansion House, under the presidency of the Lord Mayor. The report, the adoption of which was carried unanimously, showed that the income had risen since 1897 (the year in which the street collection was discontinued) from £20,138 to £30,662 in 1909, while the expenses had fallen from 12·5 per cent. to 7·9 per cent. During the same period the convalescent home letters have increased from 1351 to 1796. Two-thirds of the patients pay 5*s.* or 6*s.* a week. In 1897 the dentistry department of the Fund assisted 174 patients, while in 1909 the number has risen to 1892. In moving a resolution approving of the action of the Fund in providing assistance to those needing dental treatment, Mr. Montagu F. Hopson said that about 86 per cent. of our poorer classes were suffering from dental disease. He dwelt on the importance of providing dental treatment for children, which, if it did not eradicate dental disease in the course of a generation or so, would do much to prevent it. But treatment should be undertaken early.

TORBAY HOSPITAL, TORQUAY.—A bazaar, which realised about £700, was recently held in Torquay in aid of the funds of the Torbay Hospital.

A CORNISH CENTENARIAN.—Mrs. Mary Matthews died at Tywardreath, Cornwall, on April 13th at the age of 106 years. She was born at High Bickington, North Devon.

THE SEWAGE OF OKEHAMPTON (DEVON).—At a meeting of the Okehampton town council held recently a tender for £3983 was accepted for the purpose of carrying out works of sewerage and sewage disposal.

LONDON COUNTY COUNCIL.—The following appointments as chairmen of committees have been made: Public Health, Major C. Skinner; Asylums, Mr. H. V. Rowe; Education, Mr. Cyril Jackson; and Midwives Act, Mr. W. F. Barrett (with Miss A. S. Gregory to the vice-chair).—Long Grove Asylum has been added to the list of asylums recognised by the Conjoint Examining Board of the Royal Colleges of Physicians of London and Surgeons of England for clinical demonstrations in lunacy.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.—The result of the final ballot for the appointment of an honorary surgeon for the Royal Southern Hospital was the election by 24 votes to 12 of Mr. Douglas Douglas-Crawford, F.R.C.S. Eng., honorary surgeon to the Liverpool Stanley Hospital and lecturer in clinical surgery and surgical anatomy in the University of Liverpool. The committee of the Royal Southern Hospital is to be congratulated upon the addition to its staff.

DEMONSTRATIONS OF MODERN METHODS.—The Bristol Medico-Chirurgical Society is indebted to its secretary, Dr. J. A. Nixon, for a very happy idea. The last meeting of the society was devoted to a demonstration of modern diagnostic appliances, including direct laryngoscopy and ophthalmoscopy, some of the newest modifications of cystoscopy, the use of the polygraph, and so on. There was a good attendance of members and ample time was provided for a brief exhibition of each of the various apparatus and the method of application.

READING PATHOLOGICAL SOCIETY.—Under the auspices of this society a lecture was given by Mr. Stephen Paget on April 14th in the Town Hall, Reading, before an appreciative audience, on the subject of "What we Owe to Experiments on Animals." The lecturer, who was introduced by Dr. J. B. Hurry, the President of the society, described in a graphic manner the great strides that had been made in our knowledge of disease during recent years owing to experimental methods of investigation. At the conclusion a local branch of the Research Defence Society was formed with a strong list of names (both medical and lay) as a provisional committee.

PROFESSOR A. M. PATERSON.—The recent conference on Professor A. M. Paterson of an honorary Fellowship of the Royal College of Surgeons of England has given much satisfaction to his numerous friends in Liverpool. Professor Paterson has been professor of anatomy in Liverpool since 1894, when he succeeded the late Sir William Mitchell Banks upon the chair of anatomy being endowed by the then Earl of Derby. Professor Paterson has held many representative positions in the University. He was dean of the medical faculty of the University for nine years, resigning in 1903, when he was elected chairman. He is treasurer of the new dental hospital, in the erection of which he has taken a leading part.

A STOCKPORT HOME FOR CONSUMPTIVES.—The Stockport board of guardians has decided to provide accommodation at the Stepping Hill Hospital estate for male patients suffering from tuberculous disease. The plans for the building have been passed by the Local Government Board with some alterations suggested by the Board's architect. The site chosen is the highest on the estate and is about 300 feet above sea level. The building is to be of one storey, with an open verandah to the south and with the exercise grounds in front. The patients can be wheeled in their beds to the verandah and the most approved methods of treatment as to food, fresh air, and isolation will be adopted. At present there are 46 consumptive patients in the hospital and their removal to the new buildings will be

a great relief to the overcrowded wards. The buildings are to cost £2400 and their equipment £480.

THE Chelsea Hospital for Women has received from the trustees of the Zunz bequest a grant of £2000 to name a ward the Annie Zunz Ward.—Lord Castlereagh has accepted the office of President of the hospital.

NORTH DEVON INFIRMARY, BARNSTAPLE.—At the quarterly meeting of the governors of the North Devon Infirmary, held on April 12th, the chairman alluded to the need of increased financial support for the institution. It is estimated that for the financial year which terminates next June there will be an unfavourable balance of about £500. Owing to want of funds one of the wards has had to be closed, and consequently the occupied beds have been reduced from 60 to 40. The North Devon Infirmary performs a most useful work in Barnstaple and the district, and it is to be hoped that the residents will subscribe generously and place the charity in a sound financial condition.

THE METROPOLITAN POLICE SURGEONS' ASSOCIATION.—The annual meeting of this association was held at the Restaurant Frascati on April 14th, when the report of the council was read. During the year many matters of importance to police surgeons were considered by the council, especially the law relating to coroners and coroners' inquests; and the honorary secretary of the association, Dr. C. Owen Fowler, gave evidence before the Departmental Committee appointed by the Home Office to inquire into this subject. An innovation was a special general meeting which was held in October in the Council Chamber of the British Medical Association, when Dr. W. H. Willcox read a most instructive paper on the Medico-Legal Importance of Wounds produced by Firearms. Forty-two members attended and several took part in the interesting discussion. It is hoped to arrange similar meetings, if the members will show their appreciation by attending. Mr. H. Bott was elected President for the ensuing year, and Mr. Walter Atkins Grogono Vice-President. The honorary secretaries, Dr. Owen Fowler and Dr. G. Nicol Henry, and the honorary treasurer, Dr. C. P. Gallie, were re-elected, and a vote of thanks was unanimously passed to these gentlemen for the able manner in which they had carried out their respective duties during the past year. The meeting was followed by the annual dinner. Mr. A. F. L. Dorin was in the chair. Among the guests were Sir Edward Henry, K.C.V.O., the Chief Commissioner of the Metropolitan Police; Mr. Clinton T. Dent, the chief surgeon; Mr. Paul Taylor, the metropolitan police magistrate; and Mr. M. H. Taylor, the coroner for Kingston. After the loyal toasts had been given from the chair, Mr. Paul Taylor proposed the health of the association, and referred to the great aid which he and his fellow magistrates had always received from divisional surgeons, especially in what he facetiously termed "cases of conflicting perjury." He drew attention to the inadequate scale of fees for professional evidence, and suggested that this was a good subject for discussion by the association, and one on which they might well make representations to the Home Office. Dr. Owen Fowler in replying mentioned the fact that out of the 170 metropolitan police surgeons 153 were members of the association. The toast of "The Commissioners, Receiver, and Chief Constables" was given by Mr. Bott, and replied to by Sir Edward Henry, who made mention of certain improvements initiated by Mr. Dent, notably the arrangements for dental treatment and the admission of any venereal case into the Guards' Hospital. He also assured all present of the sympathy which requests from the association would receive from the Scotland Yard authorities. Mr. Grogono proposed the health of Mr. Dent, and Dr. W. Beech Johnston proposed that of Mr. Dorin, the chairman. Mr. Dorin, it was stated, was making on this occasion his last appearance as an active member, he having retired from practice after a membership of the association since its beginning 22 years ago, during 15 years of which he had been the honorary secretary, scarcely ever missing a council meeting, and never sparing himself any trouble for the association, the welfare of which he had so much at heart. Dr. F. G. Crookshank, in a humorous speech, expressed the satisfaction all felt at seeing the guests, which was responded to by Mr. M. H. Taylor, who feelingly mentioned the subject of fees, and especially the need for reform in the matter of payment for post-mortem examinations and coroner's court attendances by medical officers of cottage and other hospitals who, though not paid for their hospital duty, were also unpaid for this work. Between the toasts the "Queer Quakers," under the direction of Miss Lily Pritchard, added to the enjoyment of the company by their excellent rendering of songs.

DONATIONS AND BEQUESTS.—Under the will of the late Mrs. Kate Minnie Russel, the Victoria Hospital for Children, Chelsea, will receive the freehold residence of the testatrix, Koonowla, near Cudham, Kent, for the purpose of a convalescent home, with £5000 upon trust for its maintenance. Among other bequests the testatrix left £200 to the Royal Hospital for Incurables, Putney.—By the will of the late Colonel T. J. Holland, C.B., the Eye and Ear Hospital, Tunbridge Wells, will receive £500.—Under the will of the late Miss Martha Elizabeth Gray, a sum of £1000 is left to Guy's Hospital for the endowment of a bed for males in the Queen Victoria Ward of the hospital, and a sum not exceeding £200 for the endowment of a bed in Newbury Hospital.

THE LEICESTER INFIRMARY.—The 137th annual report of the Leicester Infirmary, for the year 1909, exhibits two notable features. The first is that the income has been sufficient to meet the expenditure, and the second that the deficit of £2726 brought forward from the previous year has been extinguished. During the year 3233 in-patients were treated, an increase of 87 on the preceding year; the daily average number of patients was 209. The cost per bed occupied was £76 8*s.* 4*d.*, and the cost per patient per week £1 8*s.* In the out-patient department 12,573 new cases received treatment. The total number of out-patients was 30,131. The total income for the year was £22,935. Owing to various alterations and the necessary enlargement of the institution there will probably be an extra expenditure during 1910 of £1200.

MEMORIAL TO THE LATE MR. CONNELL WHIPPLE.—A meeting was held at the Plymouth Guildhall on April 15th to consider the question of providing some memorial to the late Mr. Connell Whipple. Mr. Whipple had been for 40 years a member of the honorary staff of the South Devon and East Cornwall Hospital, and his father had also served in a similar capacity for 29 years. Consequently it was considered desirable that the memorial should be connected with that institution. After some discussion it was determined, on the motion of Sir Joseph Bellamy, seconded by Prebendary Burroughs, that the memorial should take the form of an additional operating theatre, the cost of the undertaking being estimated at about £700. Mr. Whipple was interested in the proposal for providing another operating theatre for the hospital, and was working at a scheme for promoting it at the time of his death.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Milk Legislation.

Mr. COURTHOPE has obtained for his Milk and Dairies Bill the support of Members in all parts of the House. Amongst them are Mr. GUINNESS and Captain JESSEL, who were the tellers against Mr. COURTHOPE'S motion to delete the milk clauses of the London County Council (General Powers) Bill. Other Members who are backing the Bill are Mr. WALTER LONG, Mr. HAYES FISHER, Sir LUKE WHITE, Colonel LOCKWOOD, Mr. COURTENAY WARNER, Mr. RYLAND ADKINS, Mr. CHARLES BATHURST, Mr. DAWES, and Mr. STANIER. The object of the Bill being to promote general as opposed to piecemeal legislation, makes possible the coöperation of those who took diverse views on the advisability of extending the powers of the London County Council with regard to milk-supply in a private Bill.

The Budget and Medical Men.

The Finance Bill for the year 1909-10 is being passed through the House of Commons under a closure resolution. It contains provisions for the taxation of motor-cars and motor spirit, but certain abatements are made in respect of the duties paid by medical men. The Bill leaves these abatements intact.

Public Health (Foreign Meat) Amending Regulations, Scotland.

The amending regulations made for Scotland under the Public Health

(Regulations as to Food) Act, 1907, in relation to foreign meat have been laid on the table of the House of Commons.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 13TH.

The Importation of Chinese Pork.

Mr. PETO asked the President of the Local Government Board whether he had ascertained that a part or all of the shipment of Chinese pork that was condemned and refused landing at Liverpool and London had been transhipped to the Isle of Man; whether it was being there made into bacon; whether any of such bacon was being shipped to London and Liverpool; whether, as it was impossible for experts to determine by examination that bacon had been made from diseased carcasses or not, there were any means of preventing bacon, if made from diseased carcasses of Chinese pigs in the Isle of Man, being sold in this country as English-cured, and what steps would be taken to prevent it.—Mr. BURNS replied: The consignment of pork referred to in the question was not condemned in Liverpool and London as being unfit for food. So far as my information goes, it was subjected to careful examination by British experts in China before despatch, any doubtful carcasses being rejected. This circumstance and the ordinary inspection at the ports, to which food imports are subjected, seem sufficient to remove any apprehension.

Mr. FELL: Is it not a fact that the authorities refused to allow this pork to be landed in London and that it was then sent to the Isle of Man?

Mr. BURNS: The admission of this pork into London was refused not because it was unsound, or unclean, or diseased, but because it did not comply with the technical condition that it should be completely whole and that the backbone should not be taken out.

Mr. FELL: Is it not a fact that if the pork is not completely whole, and arrives in that condition, the authorities will not allow it to be landed in London?

Mr. BURNS: They will not allow these particular carcasses to be landed in England or Wales unless they are whole.

Mr. FLAVIN: Will the right honourable gentleman make inquiries into the nature and quality of the food on which these Chinese pigs are fed?

Mr. BURNS: These pigs are not the black razor-backed scavenger pigs, but are white pigs fed on rice in the Yang-tse Valley.

Mr. REMNANT: Is it not a fact that these rice-fed pigs are so fed for only one or two days before they are slaughtered?

Mr. KILBRIDE: Is it not a fact that a certain portion of the carcass in these pigs is removed in order to prevent the effectual detection of tuberculosis?

Mr. BURNS: No; on the contrary, we insist that the carcasses shall be landed whole, so that we shall have the opportunity of seeing whether the pigs have had that disease.

Mr. KILBRIDE: Is it not a fact that a certain portion of the carcass is removed so that tuberculosis cannot be detected?

Mr. BURNS: Oh, no. The reason for which the importers remove that portion of the pig is a commercial one, because it enables them to get a greater quantity of more profitable pork without the backbone than with it.

Mr. FELL further asked the President of the Local Government Board what steps he was taking to prevent the introduction into this country of the Chinese pork which was being converted into bacon in the Isle of Man, after having been twice rejected at ports in this country.—Mr. BURNS answered: Any bacon which is imported into this country is liable to inspection by the medical officer of health, and he is empowered to seize it, if, in his opinion, it is unsound, unwholesome, or unfit for human consumption.

Mr. FELL: Is the right honourable gentleman aware that 25 bales of this bacon made from pork which was not allowed to be landed in this country, has already been received at the Union Cold Storage in London?

Mr. BURNS: I do not know.

Mr. REES: Is it suggested that an expert can tell by examination of these carcasses whether they were rice-fed or how long they were fed?

Mr. BURNS: We took the precaution to consult the British consul in the neighbourhood where these pigs are fed and in the district from which they are despatched to this country, and we are satisfied that the suggestions made by various honourable Members are unfounded.

Mr. REMNANT: May honourable Members see a copy of the report which the right honourable gentleman has received from the British consul dealing with this question?

Mr. BURNS: In August, 1909, the consul-general at Hankow reported "that the animals exported were entirely different from the ordinary scavenger pigs, and were of a special breed and fed on rice in the valley of the Yang-tse River."

A Milk and Dairies Bill.

Mr. COURTHOPE asked leave under the "ten-minutes rule" to introduce a Bill to make better provision with respect to the sale of milk and the regulation of dairies. He said that he took this course as a sequel to the debate on the London County Council (General Powers) Bill, when the majority of the House supported his instruction to the Committee to delete from it the clauses dealing with the milk-supply. He had assured the President of the Local Government Board that if his Milk Bill of last session were reintroduced to deal in a general fashion with the milk-supply it might be treated as non-controversial. He hoped that the introduction of the Bill which he (Mr. Courthope) now brought forward would satisfy the right honourable gentleman that the members representing agricultural constituencies would not offer strenuous opposition to general milk legislation. The Bill which he now asked leave to introduce was a general Bill. It might be described briefly as the Bill of the right honourable gentleman of last year with the incorporation in it of the amendments recommended by the Chambers of Agriculture. It was supported by honourable Members in all parts of the House, including honourable Members who had seats also on the London County Council, the most exacting of all the local bodies in its demands in respect to the milk question. It was supported also by representatives of the County Councils' Association. He hoped when the Bill was examined by the President of the Local Government Board he would find that a very careful comparison was necessary to detect the difference between it and the Milk Bill of last year. He trusted that the right honourable gentleman would then agree with him that this Bill could be treated as non-controversial and that he would induce his colleagues on the Treasury Bench to give facilities for it, and to allow it at least to be sent to a Grand Committee. It was in the sincere belief that the Bill was in the interests, not only of the consumers but of the producers of milk, and that general legislation on sound lines, even though the restrictions were severe, should be passed, that he asked leave to bring in the Bill.

Leave having been given, the Bill was introduced and read a first time.

THURSDAY, APRIL 14TH.

Omagh District Asylum.

Captain CRAIG asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that in the Omagh District Asylum the attendants had to go on duty at 6 o'clock A.M. and remain until 8 o'clock at night, having to work 14 hours daily, in addition to which on two nights in the week they had to remain on duty until 10 o'clock P.M.; whether these officials had frequently made representations to the committee but without effect; whether the inspectors had the power to insist on reasonable hours of service in consequence of the grant from the Government; and whether he would take steps to see that the inspectors insist on more reasonable hours being worked by the attendants in that institution.—Mr. BIRRELL replied: I understand that the facts are practically as stated, save that the attendants' hours of duty are somewhat shorter in winter. The hours of duty in the Omagh Asylum are not, as I am informed, longer than in most other asylums. The power of prescribing the attendants' duties is vested by law in the committee of management, and the inspectors of lunatics cannot interfere save in extreme cases affecting the proper maintenance of the inmates of an asylum.

Medical Referees under the Workmen's Compensation Act.

Mr. GILL asked the Secretary of State for the Home Department whether it was in accordance with the regulations relating to medical referees under the Workmen's Compensation Act for a medical man who was in partnership with an official medical referee, to examine injured persons on behalf of an insurance company when such cases might be afterwards referred to his partner for final decision.—Mr. CHURCHILL answered: It would, as a general rule, be considered incompatible with the position of a referee for his partner to hold as part of the partnership an appointment for an insurance company in connexion with the workmen's compensation case. The Home Office has not objected to the partner of a referee holding such an appointment outside the partnership agreement, so that the referee has no interest in it; and to do so would, I am afraid, militate against the department getting the best men for the post of referee.

Pneumonokoniosis amongst Ganister Miners.

Mr. STEEL-MAITLAND asked the Secretary of State for the Home Department when the publication might be expected of the report of the Royal Commission on Mines dealing with the question of pneumonokoniosis among ganister miners.—Mr. CHURCHILL said in reply: I am not in a position to make any statement at present. The Royal Commission on Mines is being reconstituted to deal with metalliferous mines and quarries, and this matter will be referred to them. I hope that their inquiry will be completed without any delay.

Superannuation Allowances of Vaccination Officers.

Colonel RAWSON asked the President of the Local Government Board whether the superannuation allowances of vaccination officers were still based on the average salary received during the last five years; and whether, in view of the fact that the fees of vaccination officers were so greatly reduced by reason of the facility with which exemption from vaccination was now obtained, he would reconsider the matter, with a view of meeting the altered conditions.—Mr. BURNS (by written answer) replied: Under the provisions of the Poor-law Officers' Superannuation Act, 1896, the superannuation allowances are based on the average amount of salary and emoluments received during the five years immediately preceding the date of retirement. In the case of officers who have suffered loss for the reason mentioned I have been willing to sanction gratuities, and such gratuities would count as emoluments for the purpose of pension. In other cases the special circumstances have been met by allowing an addition of years under the provisions of Section 5 of the Act to an officer on retirement.

MONDAY, APRIL 18TH.

Asylum Officers' Superannuation.

Sir WILLIAM COLLINS asked the Secretary of State for the Home Department whether he could state approximately the number of asylum officers who would be entitled to assured pensions under the Asylum Officers' Superannuation Act, 1909; and whether he could say approximately what proportion of the total number of officers had been placed in Class I. and Class II. respectively by the visiting committees, as directed by Section 1 of the Act.—Mr. CHURCHILL wrote in reply: The Commissioners in Lunacy state that they have no recent information which would enable them to state approximately the number of asylum officers who will be entitled to assured pensions under the Asylum Officers' Superannuation Act, 1909. In 1906, however, they obtained a return which showed that for the past five years the average number of attendants and nurses employed in asylums was 10,100. The present number would probably be larger, several new asylums having been opened. The Commissioners cannot say what proportion of the total number of officers have been placed by the visiting committees in Class I. and Class II. respectively, as directed by Section 1 of the Act. It is not known whether all the visiting committees have yet come to a decision as to how the various officers in their employ shall be classified.

TUESDAY, APRIL 19TH.

Forcible Feeding.

Mr. HUGH LAW asked the Secretary of State for the Home Department whether his attention had been called to the recent death in Portsmouth Prison of John Pattle; whether this man's death was due, according to the coroner's verdict, to heart disease; whether he had been twice forcibly fed; and whether he had been medically examined before forcible feeding was authorised.—Mr. CHURCHILL replied: My attention had not been previously called to this case. On inquiry I find that the prisoner was committed on remand on a charge of attempting suicide—his second attempt. He appears to have been of unsound mind and could not be persuaded to take food. Food had therefore to

be administered by force. His heart was tested first, but artificial feeding was in this case the only alternative to allowing him to commit suicide. According to the medical evidence, death was due to heart disease and not in any way to forcible feeding, which probably prolonged his life. The coroner's jury expressed the opinion that he had received every consideration at the hands of the prison officials.

Mr. HUGH LAW further asked the right honourable gentleman whether his attention had been called to the inquiry held on March 8th by the Salford coroner into the death of Mary Pilsbury, in which a verdict of suicide was returned; whether the girl had just been released from prison; whether she had been forcibly fed whilst in prison; whether she left a note saying that this had been her first experience of this treatment and would be her last; and whether he proposed to take any steps with regard to the regulations for forcible feeding of prisoners.—Mr. CHURCHILL answered: My attention has not been called otherwise than by the honourable Member's question to the inquest held on Mary Pilsbury, but I find on inquiry that it was found necessary to administer food by force to this girl on three occasions when she was serving a sentence of one month's imprisonment last July, and on three occasions again during another term of imprisonment last November. She was received in prison again on Jan. 10th last and compulsion had to be used again for 13 days, but from Jan. 26th till her discharge on March 5th she took food naturally. She never made any threat of suicide while in prison, and I believe her suicide was due to circumstances quite unconnected with her imprisonment. The House is familiar with the arguments upon the general question of the forcible feeding of prisoners who refuse to take food voluntarily, and they do not appear to me to be affected in any way by this case.

Mr. LAW asked whether, in view of these two cases, the right honourable gentleman would be prepared to hold an inquiry into the whole question of forcible feeding.

Mr. CHURCHILL replied that that was a question of which he ought to have notice. If the honourable Member would put a question on the paper he would answer it. He could not at the moment hold out a hope that such an inquiry would be held.

BOOKS, ETC., RECEIVED.

AMERICAN MEDICO-PSYCHOLOGICAL ASSOCIATION (Secretary-Treasurer: Dr. C. W. PILGRIM, Poughkeepsie, N.Y.).

Proceedings of the American Medico-Psychological Association at the Sixty-fourth Annual Meeting held in Cincinnati, Ohio, May 12-15, 1908. Price not stated.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

BATLEY, A. B., L.R.C.P. Lond., M.R.C.S., has been appointed Bacteriologist in Joint Charge of the New Department for Therapeutic Inoculation at the Royal Boscombe and West Hants Hospital.

BROWNLOW, H. L., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Henley-on-Thames District of the county of Oxford.

CURTIS, GEORGE HERBERT, M.R.C.S., L.R.C.P. Lond., L.D.S. Eng., has been appointed Honorary Dental Surgeon to the Royal Hospital for Diseases of the Chest.

DAVIDSON, NORMAN G. W., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Assistant Medical Officer to the Rio Tinto Company, Rio Tinto, Spain.

EASON, A. M., L.R.C.P. & S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Lytham District of the county of Lancaster.

FACEY, W. E., M.B. Camb., M.R.C.S., has been appointed Bacteriologist in Joint Charge of the New Department for Therapeutic Inoculation at the Royal Boscombe and West Hants Hospital.

GRIEVES, J. P., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Portishead District of the counties of Gloucester and Somerset.

GRIFFITH, WILLIAM, M.B., Ch.B. Vict., M.R.C.P. Lond., has been appointed Physician to St. John's Hospital for Diseases of the Skin, Leicester-square.

GRUNER, OSKAR C., M.D. Lond., has been appointed Pathologist to the Royal Victoria Hospital, Montreal, and Lecturer in Pathology of McGill University.

HEAVEN, JOHN COOKESLEY, L.R.C.P. Lond., M.R.C.S., L.S.A., D.P.H. Lond., has been appointed Medical Officer of Health to the Keynsham (Somerset) District Council.

HICKS, J. A. BRAXTON, M.B., B.S. Lond., has been appointed Assistant Pathologist and Curator of the Museum at Westminster Hospital.

HOWARD, A., M.B., B.S. Vict., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Chapel-en-le-Frith District of the county of Derby.

LEWIS, W. C., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Denbigh District of the county of Denbigh.

MOORE, S. P., M.B., Ch.B. Edin., has been appointed House Surgeon at the Torbay Hospital, Torquay.

PHILLIPS, HUBERT, M.R.C.S., L.S.A., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

PLANCK, CHARLES, M.R.C.S., L.R.C.P. Lond., has been appointed Medical Superintendent to the Brighton County Borough Asylum, Haywards Heath.

RICHARDS, JOSEPH STEWART, M.D., B.S. Lond., has been appointed Honorary Medical Officer to the Croydon General Hospital.

SIBLEY, W. KNOWSLEY, M.D. Cantab., M.R.C.P. Lond., has been appointed Assistant Physician to St. John's Hospital for Diseases of the Skin, Leicester-square.

STEELE, RUSSELL, M.D. Durh., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Consulting Surgeon to the West Herts Hospital.

WELCH, T. A., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Whaley Bridge District of the county of Chester.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BRIDGWATER HOSPITAL.—House Surgeon, unmarried, for six months. Salary at rate of £100 per annum, with board, lodging, and washing.

BRISTOL GENERAL HOSPITAL.—Casualty House Surgeon. Salary £60 per annum, with board, residence, &c.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—Senior Resident Officer. Salary £100 per annum, with rooms and attendance.

BURY INFIRMARY.—Senior House Surgeon. Salary £110 per annum, with board, residence, and laundry. Also Junior House Surgeon. Salary £80 per annum, with board, residence, and laundry.

BUXTON, DEVONSHIRE HOSPITAL.—Assistant House Surgeon for six months. Salary at rate of £70 per annum, with apartments, board, and laundry.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—House Surgeon, unmarried. Salary £80 per annum, with board, lodging, and washing.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.—House Surgeon. Salary 40 guineas per annum.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Clinical Assistant.

DENBIGH, DENBIGHSHIRE INFIRMARY.—House Surgeon. Salary £100, with board, residence, and washing.

DEPTFORD MEDICAL MISSION.—Locum Tenens Medical Superintendent.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant Resident Medical Officer, unmarried, for six months. Salary at rate of £50 a year, with board, apartments, and laundry.

DOUGLAS, NOBLE'S ISLE OF MAN GENERAL HOSPITAL AND DISPENSARY.—Resident House Surgeon, unmarried. Salary £90 per annum, with board and washing.

DRIFFIELD UNION.—Medical Officer and Public Vaccinator. Salary £21 per annum, with extra medical and vaccination fees.

ELHAM UNION.—Medical Officer. Salary £25 per annum, with vaccination fees about £35.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, London, S.E.—House Surgeon for six months. Salary at rate of £60 per annum, with board, residence, and washing. Also Honorary Dental Surgeon.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with board, residence, and laundry.

HEMEL HEMPSTEAD, WEST HERTS HOSPITAL. — House Surgeon. Salary £100 per annum, with rooms, board, and washing.

HOSPITAL FOR EPILEPSY AND PARALYSIS AND OTHER DISEASES OF THE NERVOUS SYSTEM, Maida Vale, W.—Resident Medical Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

HULL, ROYAL INFIRMARY.—House Physician, unmarried. Salary £100 per annum, with board and apartments. Also Assistant House Surgeon. Salary £80 per annum, with board and lodging. Also Casualty House Surgeon. Salary at rate of £60 per annum, with board and lodging.

LEEDS GENERAL INFIRMARY.—House Physician and House Surgeon for six months. Also Ophthalmic House Surgeon. Salary £50 per annum. Board, washing, and lodging in each case.

LEICESTER INFIRMARY.—House Physician. Salary at rate of £100 per annum, with board, apartments, and washing. Also Assistant House Physician and Assistant House Surgeon. Salary at rate of £60 per annum, with board, apartments, and washing.

LONDON HOSPITAL, Whitechapel, E.—Assistant Surgeon.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT AND CHEST.—Resident Medical Officer. Salary £100 per annum, with board, apartments, and washing.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, Chenies-street, W.C.—Pathologist. Salary £120 per annum, with rooms, coals, light, and attendance.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—House Physician. Salary £75 per annum, with board and residence. Also Clinical Assistants for six months.

NEWCASTLE-ON-TYNE DISPENSARY.—Visiting Medical Assistant. Salary £160 per annum.

OLDHAM GENERAL INFIRMARY.—Senior House Surgeon. Salary £120 per annum. Also Second House Surgeon. Salary £100 per annum. Also Third House Surgeon. Salary £80 per annum. All for six months, with residence, board, and laundry.

PRESTON, LANCASHIRE EDUCATION COMMITTEE.—Two School Medical Inspectors. Salaries £250 per annum.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Assistant Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, residence, and washing.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—Resident House Surgeon, unmarried, for six months. Salary £100 per annum, with board, residence, and washing.

ROYAL NAVAL MEDICAL SERVICE.—Examination for Fifteen Commissions.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand, W.C.—House Surgeon. Salary at rate of £50 per annum, with board, residence, and laundry.

RUTLAND COUNTY COUNCIL.—County Medical Officer of Health and County School Medical Officer. Combined salary £400 per annum.

ST. GEORGE'S INFIRMARY, Fulham-road, West Brompton, S.W.—Second Assistant Medical Officer. Salary £120 per annum, with board, residence, and washing.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square, W.—Honorary Anæsthetist.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.

STOKE-ON-TRENT, NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill.—Junior House Surgeon for six months. Salary at rate of £50 per annum, with board, apartments, and washing.

SWANSEA GENERAL AND EYE HOSPITAL.—House Physician. Salary £75, with board, washing, and attendance.

TAUNTON, TAUNTON AND SOMERSET HOSPITAL.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

VENTNOR, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—Two Assistant Resident Medical Officers, unmarried. Salary £100 per annum each, with board and lodging. Also Holiday Locum Tenens for four months. Salary £3 3s. per week.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Surgeon for six months. Salary £30, with board, lodging, and laundry.

WALTHAMSTOW, LEYTON, WALTHAMSTOW, AND WANSTEAD CHILDREN'S AND GENERAL HOSPITAL.—Resident House Surgeon. Salary £100 per annum, with board, rooms, and washing.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon. Salary at rate of £80 per annum, with board, rooms, and laundry.

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £130 per annum, with board, lodging, and attendance.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Newport in the county of Mayo; and at Dungiven, in the county of Londonderry.

THE Secretary of State for the Home Department gives notice of a vacancy as Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuit No. 1, attached more particularly to Morpeth and Blyth, North Shields, Newcastle, Gateshead, Hexham and Bellingham County Courts.

Births, Marriages, and Deaths.

BIRTHS.

HARTIGAN.—On April 14th, at Gloucester-terrace, W., the wife of Thos. Hartigan, M.D., of a son.

MOON.—On April 16th, at Green-street, W., the wife of R. O. Moon, M.D., of a daughter.

PINCOTT.—On April 12th, at Culverden Grange, Tunbridge Wells, the wife of James C. Pincott, M.R.C.S. Eng., L.R.C.P., of a daughter.

SEALE.—On April 10th, at The Shrubbery, Farnborough, Kent, the wife of E. A. Seale, B.A., M.D., of a son.

MARRIAGES.

GLENNIE—HASTINGS.—On April 13th, at St. Andrew's Cathedral, Singapore, John Arthur Rinder Glennie, M.B., C.M., D.P.H., to Dora Mary, second daughter of Major-General F. E. Hastings, C.B., Indian Army.

RUTTER—AYERS.—On April 9th, at St. Leonard's, Streatham, William Stanley Rutter, L.D.S. Eng., to Evelyn Margery, second daughter of Mr. and Mrs. Mowbray Ayers, of Hopton-road, Streatham.

SEDGWICK—WYLIE.—On April 16th, at St. Saviour's Church, South Hampstead, George Henry Sedgwick, M.R.C.S., L.R.C.P., to Kathleen, younger daughter of James Hamilton Wylie, M.A., D. Litt.

STEVENSON—VERRAN.—On April 14th, at the Streatham Wesleyan Church, Claude Maberly Stevenson, M.B., B.C., to Dorothy Thirza, second daughter of Joseph Verran, of Streatham Hill, S.W.

DEATHS.

WINDSOR.—On April 13th, at Brownslow, Great Budworth, Cheshire, Thomas Windsor, M.R.C.S., L.S.A., in his 79th year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE NURSE, THE PRAM, AND THE ADENOID.

To the Editor of THE LANCET.

SIR,—I start by saying that the collocation of my title is only justified in theory, but I add that I believe in my own theory. A baby arrives—howling. This has nothing to do with this being a bad, bad world. He howls because, after months of crumpled comfort, his legs are pulled out straight for the first time. It may be a bad world; yet he feels hurt at being forced to go straight. But he must be strong enough to face worse things than physical rectitude; there is the 1910 domestic nurse. This female is none of your old-fashioned folk who cossets a taut little tummy with an ample hand; who brews the genial cinder tea; who gropes after truth by the aid of experimental diet, giving muscularity to the large intestine of the strong and colour to the marasmal certificate of the weak.

The plain and simple wage-earning nurse went out when her class got education and discovered the tired back; her successor is appreciating that the modern nursery is a soft job for a salaried attendant. So this nurse of to-day is a nurse of thermometers, costumes, patent foods, subscriptions to a professional organ, and economies of muscular effort. She is attractive, and baby's mother fancies the young woman in her elegant uniform, and notes her pronunciation and is glad that her baby will not start speech by talking of 'orses and 'ouses, nor will pat sand into a pail pronounced—"hæmorrhoid."

When baby is a bit more grown up he will know the modern catchphrase of "labour saving"; this principle produced perambulators, and conduced to their name being abbreviated into "pram." The primal "pram" was a three-wheeler, iron-tyred, with a chair seat arranged at such height as prevented the feet reaching the floor; a necessary strap kept the child on the shiny cushion. An airing in this weighty vehicle included a good jolting, with healthy fatigue perhaps; whilst the gritting wheels prepared the rider for the strenuous life. To its further credit, no mere babe could be laid down in this old pram. Consider the baby carriage of to-day—a light construction on its four rubber-tyred wheels and gentle springs, with mattress, monogramed quilts, fur rugs, hot water bottles, umbrella basket, hoods and windscreens, Teddy bear, crest on the panels, and a china handle to which is attached the elegant nurse. Gains, clear gains, surely!

Does baby say so? Or is his fancy for a good thick arm to hold him and an expansive cushiony bosom to loll against, with tender involuntary massage as a result? So would his back acquire muscle, so would he learn to sit up and look his world in the face. Carried on the arm baby was sure of nurse's undistracted attention; a harmony of energy or fatigue embraced the two, temperature and telepathy were in accord between them; whilst among the chiefest boons to baby was the avoidance of that most pernicious of positions, the supine, which seems inseparable from the use of the modern baby-carriage.

Put an unclothed and unhampered infant on a suitable flat surface and observe the attitude naturally taken. The infant turns on one side, draws up the legs, and inclines the face downwards—in fact, lies curled up on his side.

Why is every infant in a baby-carriage lying on the back? Firstly, the body of the baby-carriage may be too narrow to permit the assumption of any other posture. Then the mattress is not really flat but concave and every movement of the carriage tends to lay the child out at the bottom of this saucer. And how is this baby clothed? In accordance with the posture he assumes. The mother or the nurse wants, probably both want, the pleasure of dressing the baby in smart clothes. These clothes have sleeves and armholes—armhole over armhole surrounds the tiny limb till the axilla is stuffed full of material; napkins and clothing fill the space between the thighs; then, once on his back, the baby is star-fished for good—an he would he could not roll off it. Baby is pretty—they all tell the mother so. And how, pray, is one to see this if the child lies curled up on his side? Such a pose is in contravention of nurse etiquette and a dead loss to the passing public.

And thus baby lies on his back, his limbs and abdomen passive, while mucus soaks the patch where his adenoid crop is being cultivated, and he is learning to breathe through his mouth. The pleasant rhythm of the easy carriage invites sleep: he sleeps now, perhaps he won't to-night.

I am, Sir, yours faithfully,

April 18th, 1910. CURMUDGEON.

SCHOOL TEACHERS AND THE PREVENTION OF THE SPREAD OF INFECTION.

IT is only by the coöperation of laymen that the full benefit of the public health laws can be obtained, and Dr. A. Mearns Fraser, the medical officer of health of Portsmouth, is to be congratulated on the production of a little pamphlet entitled "Notes on Infectious Diseases," which he has issued with the object of helping assistant teachers in the elementary schools to coöperate effectively with the health department in preventing the spread of infectious diseases. Both the notifiable and non-notifiable diseases are dealt with in a simple and practical manner, and only such points as are likely to prove of value in enabling teachers to act with promptitude and discretion are emphasised. If the information contained in this pamphlet is digested and promptly applied by school teachers and attendance officers there would be less danger of our elementary schools becoming centres for the spread of disease. The pamphlet is issued by the health department of Portsmouth.

EXPLOSIVE COUGH MIXTURE.

To the Editor of THE LANCET.

SIR,—I am glad that the little memorandum of mine which you published under the above heading in THE LANCET of Feb. 26th has attracted so much attention. I do not know, however, that we are much nearer to a solution of the cause *malgré* your own admirable article of March 26th, for it is now clear that explosions have occurred where no nitrous ether was contained in the mixture. I regret that I cannot myself throw any light on the subject. A well-informed military medical friend has a theory of his own which, as I believe he contemplates sending it to THE LANCET, I will not detail here. Almond emulsion makes a very nice menstruum, and it is to be regretted that so far its abandonment seems the most likely outcome of the correspondence. Such a course will be the more inconvenient, as there is no reason to assume that other vegetable menstrua might not contain among them some one equally suitable and equally explosive. Why do not some of the therapeutic committees investigate the whole subject thoroughly? I must say that practitioners are not entirely blameless in the matter, as we ought long since to have brought the fact under the notice of the medical public. At the same time, one is entitled to ask what were materia medica lecturers doing, and what, again, these therapeutic committees? My own experience is not as tragic a one as that of the eminent physician quoted by Dr. Ninian Falkiner. It lay on this last occasion more in the humorous direction, for the mixture was ordered for an important "pretender to physic," and the latter, I have reason to think, took it into his head that it was done for the deliberate purpose of making an end of him, and so getting rid of the rival near my throne. I am satisfied that my explanation to him might as well have been addressed to the winds.

I am, Sir, yours faithfully,

Cashel, April 13th, 1910. THOMAS LAFFAN.

To the Editor of THE LANCET.

SIR,—The decomposition that may take place in mistura amygdalæ is well known, though no satisfactory explanation has been given. It appears not to be simply a fermentative decomposition, as is shown by the fact that it occurs in the presence of a good proportion of spirit of chloroform.

The following combinations have frequently been found, in my own experience, to explode spontaneously, especially if a full bottle be stored in a warm place:—

(*a*) Sweet spirit of nitre, syrup of red poppy, almond mixture.

(*b*) Paraldehyde, almond mixture.

That paraldehyde and almond mixture form an explosive combination is noted in the British Pharmaceutical Codex (1907, p. 830).

I am, Sir, yours faithfully,

London, W., April 13th, 1910. F. W. GAMBLE,

THE WILTSHIRE COUNTY NURSING ASSOCIATION.

THE sixth annual meeting of the subscribers of the Wiltshire County Nursing Association was held at Marlborough College on April 14th under the presidency of the Marchioness of Lansdowne. The society has now 31 local nursing associations and has trained 50 women as village nurses who are now nursing in various parts of the county The society also has 50 affiliated associations, employing 85 nurses. The Marquis of Bath, in alluding to the administration of the Midwives Act, said he believed that work of that kind would be much better carried out by voluntary associations, such as the Wilts County Nursing Association, than by a Government department or an administrative body.

THE THERAPEUTICS OF OXALIC ACID.

To the Editor of THE LANCET.

SIR,—Your note on oxalic acid in food prompts me to state that I have used it with apparent success in sciatica. The dose given was one grain three times daily. The "British Pharmaceutical Codex" suggests that the dose is from a quarter to a half grain, but I have found that this can be exceeded with impunity.

Many observers believe that oxalic acid, or at least some of the oxalates, have a specific effect in inflammatory conditions of the gastric mucous membrane. Such has been my experience with oxalate of cerium, which I have used pretty extensively for the purpose.

It is stated that a lemonade of oxalic acid—five or six grains to the pint—is used in France as a febrifuge. I have not tried so daring a dose, but am inclined to think that so much might be taken with safety.

I am, Sir, yours faithfully,

J. C. MCWALTER, M.D. Brux., F.F.P.S. Glasg.

Dublin, April 18th, 1910.

WANTED—SUGGESTIONS FOR TREATMENT.

A CORRESPONDENT asks for suggestions in the treatment of an obstinate case of nocturnal enuresis of 18 months' duration. The patient, a girl, aged 18 years, with well-marked symptoms of Graves's disease, passes through the day a fairly normal amount of urine and has no frequency of micturition or incontinence, but during the night she passes three pints. She sleeps heavily and is awakened with great difficulty. All the usual remedies have been tried without any permanent success, though each new treatment is efficacious for a night or two. Recently she has had injections of pituitary gland, and while she is having them her trouble was relieved, but it returned when they were discontinued. Pituitary gland by the mouth was ineffective and thyroid gland met with only temporary success.

DAVIDSON'S THERMO-GENERATOR.

THE production of an electric current by heating dissimilar metals in contact has long been known and the instrument known as the thermopile invented by Nobili gave, on account of its great delicacy, a considerable impetus to the study of radiant heat. The principle of Davidson's thermo-generator is the same, but by paying careful attention to the metals which would give the greatest electric advantage, and by placing them in a position most favourably situated for the production of a current, an apparatus has been made which gives a very sensible amount of current. In appearance the thermo-generator is like a small gas furnace used in chemical laboratories for combustions. The dimensions of a convenient-sized generator, and one which will readily illuminate small 4-volt surgical lamps, are 15 × 7 × 4½ inches and it weighs 5½ pounds. A slightly larger one, with 3½ pounds added to its weight, has a greater capacity. The amount of gas consumed is very small, and when the current is generated, which is within a minute of lighting the gas, the flames can be reduced. Methylated spirit may be used instead of gas, so that the apparatus is available for surgical illumination or for charging accumulators for that purpose where there is no electric current. The apparatus is most ingenious and its action is very interesting to watch. A principle is obviously involved which some day may be turned to great practical purposes. Messrs. F. Davidson and Co. exhibit the apparatus at 29, Great Portland-street, London, W.

THE "MACNAIR" AUTOMATIC WATER STERILISER.

THE principle upon which this steriliser works is that of a syphon, the action of which is very important, since no water can be delivered through the syphon into the reservoir until sterilisation is secured. In fact, water cannot be raised from the boiler until an accumulation of steam pressure arises which then forces the sterilised water up the syphon into the reservoir. The steriliser consists, in short, of two cisterns fitted one on top of the other. The lower cistern is the boiler, which is practically steam-tight; the upper cistern is a locked reservoir. They are connected by a pipe, or, as we have called it, a syphon, up the centre. This is an ingenious, safe, and simple arrangement, and, moreover, the sterilised water which it produces is, relatively speaking, palatable, since the water is not over-boiled, and therefore contains a proportion of dissolved air. Messrs. Allen and Hanburys, of Wigmore-street, London, W., are the manufacturers.

WANTED—A HOME.

Medicus (34, Rectory-road, Stoke Newington, London) is anxious to find a home for a medical man—a neurasthenic subject—who requires good air and a healthy environment under which he would be capable of plenty of light work. The patient is anxious to regain his health, and can afford to pay £1 per week in addition to giving his services in any way that may be useful.

Experience.—We think our correspondent might consider the point which he has laid before us and raise the question in rather a broader manner. Everything that he has to say against the unfit female can, it seems to us, be urged with equal force against the unfit male. Certainly the childless marriage so regularly attributed to the female is very usually the fault or default of the male.

Enquirer.—We cannot follow in our correspondent's letter exactly what the pathological condition is, but if the medical man in charge of the case communicates with us we will try to help him in his difficulty. We have attempted to trace the treatment spoken of without success.

Zephyr will find the information he requires in "Diagnostic de la Méningite Cérébro-spinale à Méningocoques par la "Précipito-reaction,'" H. Vincent, Bulletin Académie de Médecine, 1909, 3 S., vol. lxi., pp. 326–332.

Inquirer (2) appears to us to have behaved in an absolutely proper manner. We are glad to note also that the patient reciprocated.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

MONDAY.

ODONTOLOGICAL SECTION (Hon. Secretaries—D. P. Gabell, E. B. Dowsett, J. Howard Mummery) at 15, Cavendish-square, W.: at 8 P.M.

Paper:

Mr. A. Hopewell Smith: Two Odontoceles and Some Other Cysts.

Casual Communications:

Mr. C. Schelling: (1) Two Cases of Suppuration in the Maxilla, and (2) a Case of Neuralgia due to Impacted Lower Wisdom Teeth, in all of which Skiagrams helped the Diagnosis.

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 35, Rue Franklin, Asnières, Paris.

An Address
ON
AMPUTATIONS AT THE HIP AND SHOULDER
(INCLUDING INTERSCAPULO-THORACIC), AND ADVOCATING THE PRELIMINARY LIGATURE OF MAIN VESSELS IN OTHER AMPUTATIONS.

Delivered before the Northumberland and Durham Medical Society on March 10th, 1910,

BY CHARLES BARRETT LOCKWOOD, F.R.C.S. ENG.,
SURGEON TO ST. BARTHOLOMEW'S HOSPITAL, LONDON.

MR. PRESIDENT AND GENTLEMEN,—I propose to put before you some amputations at the hip and shoulder. This series of major amputations has impressed me with the extreme importance of avoiding hæmorrhage. Hæmorrhage and shock are almost synonymous terms. The chief step in preventing hæmorrhage during amputation at the hip and shoulder has been the preliminary ligature of the great vessels. I shall conclude by advocating the extension of this step to amputations elsewhere, more especially to those of the arm and thigh.

I am emboldened to speak about amputations because I have observed how little attention the subject has of late received. Nevertheless, it seems reasonable to suppose that the last word has not yet been said upon this important branch of surgery. I wonder whether all surgeons feel quite so keenly a disaster after a major amputation as they would one from septic peritonitis after laparotomy. But amputations have often to be performed upon patients who are gravely and critically ill, and I am convinced that more of these would recover if every drop of blood were saved during the operation.

In referring to the cases I do not propose to enter into minute details. The first step has always been to ligature and divide the main artery; the second to elevate the limb to economise its blood[1] and then to secure the great vein; and the third to amputate the limb in a methodical and leisurely manner. The flaps are fashioned of skin and muscle, using a small knife for the purpose. The shape of the flaps and the position of the incision are determined by the conditions at the time of amputation. Muscles infected with sarcoma have been, as far as possible, divided at or near their attachments. If necessary a separate vertical incision has been made to ligature the main vessels. It is a matter of little moment whether this be done or whether the amputation incision be used for that purpose. Three cases of interscapulo-thoracic amputation will be given first.[2]

INTERSCAPULO-THORACIC AMPUTATION.

The following case, which culminated in interscapulo-thoracic amputation, is full of instruction. It shows the hopelessness of inadequate operations for malignant disease, and also how cautious we should be in making a clinical diagnosis.

CASE 1.—The patient was a thin woman, aged 48. Two years before I first saw her an operation had been done for the removal of the right breast for carcinoma. The mammary gland had been taken away and some of the pectoral and lower axillary glands. The same surgeon did two more operations for removal of axillary glands, but without removing the pectoral muscles. As might have been expected after such inadequate attempts, the cancer continued to grow in the axillary glands. These required removal, but in the meantime another complication had arisen. A tumour had grown in the left breast. Taking its clinical characters and the history into consideration, most would have assumed that this was a carcinoma. On July 19th, 1904, it was incised. Competent observers pronounced it to be a carcinoma, but the immediate microscopical sections were those of excised chronic mastitis with cysts. So that after this had been removed the growth in the right axilla was taken in hand. After the pectoral muscles had been removed a number of carcinomatous glands were found reaching nearly to the clavicle. To get these away the axillary vein had to be tied and a portion of it excised. Great difficulty was experienced in removing some growth along the subscapular artery and its branches, although a part of the latissimus dorsi was taken away in the attempt. But in the end I could not help feeling doubtful whether I had got away a prolongation which ran backwards above and below the long head of the triceps. I made up my mind that should recurrence take place nothing short of interscapulo-thoracic amputation would afford any reasonable chance of safety. Rather a heavy price to pay for the first inadequate operation. Recovery was uneventful with the exception of some temporary loss of power and swelling of the right arm.

Four months later (Nov. 8th, 1904) the patient returned, and it was thought that there was some enlargement of the glands in the neck, so I exposed the posterior triangle by the usual incision; but, in spite of a prolonged search, I could find no enlarged lymphatic glands. From my experience of other cases I believe this delusion was caused by the posterior belly of the omohyoid muscle, which contracts when it is touched, and in thin people feels like a small lump. For another year (until Nov. 21st, 1905) everything seems to have gone well. Then the arm became very painful, œdematous, and nearly useless. There was a quantity of hard scar in the axilla. On Nov. 21st, 1905, some of this was removed and consisted of fibrous tissue with scattered groups of cancer cells. Recalling my former operation, at which the backward growth of cancer was found, I proceeded to perform interscapulo-thoracic amputation. The pectoral muscles had already been removed and no axillary vein was met with. After the clavicle had been divided the subclavian artery was tied and the arm slowly and quietly removed, every bleeding point being immediately secured. The division of the brachial plexus caused no shock. The operation took about one and a half hours, very little blood having been lost. It was followed by a moderate amount of shock and the patient rapidly recovered, the wound having healed by first intention.

The interscapulo-thoracic amputation was justified by what was afterwards found. Carcinoma had grown along the axillary border of the scapula and into the subscapular and infraspinous fossæ. Cancer cells were also seen in the cords of the brachial plexus. This probably accounted for the severe pain.

But this was not the end of this unfortunate patient's sufferings. On May 8th, 1906, nearly two years after my original operation, I performed a seventh operation and removed under gas a small nodule of spheroidal-celled carcinoma from the left side of the chest wall. It may be remembered that previously a part of the left breast had been excised for chronic mastitis with cysts. There is no record of this woman's death at Somerset House, so that she may yet live.

The second case of interscapulo-thoracic amputation illustrates the extreme malignancy of chondro-sarcomata; also, how the wound may be infected by the air—usually a danger during such a long operation and with such a big open wound.

CASE 2.—On July 20th, 1909, an attempt was made to remove an ossifying chondro-sarcoma springing from the neck of the scapula at the base of the coracoid process. The patient was a man, aged 64 years. Although the growth had a stalk, yet it infiltrated the neck of the scapula near the base of the coracoid process, and it was doubtful whether some of it had not been left behind. Interscapulo-thoracic amputation afforded the only possibility of removal. That was done on July 31st. The incision which had been made in the attempt to remove the tumour was enlarged—much blood had been effused. After a quantity of clot had been turned out the clavicle was sawn through and the subclavian artery and vein tied and divided. The blood effusion made this step difficult. Clearly it would have been better that the growth had not been touched. The amputation was completed in the usual way. Bleeding from the small vessels was stopped at once and there was very little loss of blood. Again there was no obvious shock when the brachial plexus was divided. A large drain was left in the lower end of the wound. The shock afterwards does not seem to have been severe; the temperature fell from 98·8° F. to 98° F., the

[1] See also A. Webb Jones, THE LANCET, April 24th, 1909, p. 1208.
[2] I am greatly indebted to my house surgeon, Mr. P. T. Spencer-Phillips, for the trouble he has taken in supplying me with the notes of the hospital cases.

pulse being 84 and respirations 20, nor was reaction marked, for the temperature merely rose to 99° F. and the pulse and respirations remained the same.

The wound became infected and a severe illness ensued, followed by rather slow recovery. The infection was bacillus aerogenes encapsulatus. When such a calamity takes place we always have a searching inquiry made, and I am indebted to Dr. M. H. Gordon for the trouble he took in investigating the source of infection. A film taken from the wound as soon as infection was suspected was crowded with a large Gram-positive bacillus with a capsule. A guinea-pig injected with some of the exudation died in 24 hours from emphysematous gangrene and its fluids were full of the same bacillus, which grew anaerobically on agar and in milk. It corresponded to the bacillus aerogenes capsulatus of Welch, and also gave the characteristic change in milk known as Klein's enteritidis change, so that the kind of infection is not in doubt. Dr. Gordon ascertained whence it came. He says that having previously recovered this micro-organism from the open air, from the dust of rooms, from dirt deposited by boots, and from fæcal matter, it was thought probable that the wound had been infected from air at the time of operation, which took at least one and a half hours. So the next time I operated in that theatre Dr. Gordon exposed plates for two hours all round the theatre and obtained the same bacillus from a plate between the operating table and the door. Smoke experiments showed that a current of air passed from the door over the table to a fan, and that this current of air drew with it dust deposited by people's boots on the outside landing. The uses of adversity are sweet. Steps have been taken so that in future this source of contamination may be avoided.

Thanks to Mr. John Adams and Dr. Hubert Chambers I have learnt the after-history of this patient. Dr. Chambers informs me that he died in December, about five months after the original operation, from pleuritic effusion on the right side, the original tumour having been on the left. Dr. Chambers had no doubt but that this was due to a secondary growth, for he aspirated twice and removed blood-stained serum. He could not detect any recurrence in the scar or glands.

CASE 3.—Interscapulo-thoracic amputation was also performed on April 12th upon a man, aged 25 years, who had a large sarcoma of the scapula, filling the supra- and infra-spinous fossæ, and complicated by growth in the glands of the axilla and the posterior triangle of the neck. It is said that a swelling had been noticed for less than six weeks; stiffness and pain seem to have been the leading symptoms. As it was obvious that the man would speedily die if left alone, I thought it right, after consultation with my colleagues, to attempt to prolong his existence. The anterior incision was begun almost at the top of the posterior triangle of the neck, and after the external jugular vein had been tied and the clavicle sawn through, the subclavian vessels were tied and the limb removed, together with the enlarged lymphatic glands. Some of these reached inwards so far that part of the sterno-mastoid muscle had to be divided before they could be removed. This formidable operation lasted 1 hour 55 minutes; the shock was more than usual, but was easily and quickly overcome by injections of strychnine and the administration of a pint of saline solution with brandy in it. The patient made rapid recovery; his evening temperature was 99°F. for several days, and the quickest pulse-rate 100 on the third day. It is to be doubted whether reaction would have been so speedy and the improvement so lasting had his blood not been economised. Within a fortnight all the stitches had been removed, the wound having healed except a very small piece in the centre, which speedily closed. This man went to our convalescent home, but I regret to say the growth soon returned, and he died about two months afterwards. We had to deal with one of the most malignant types of sarcoma, for the pathological report says that the growth was soft and consisted of large round cells.

Glancing over these three cases of interscapulo-thoracic amputation I cannot help being struck by the moderate amount of shock—on no occasion did it give rise to serious anxiety—and next by the quick recovery. Even the case of serious sepsis was able during the height of his illness to sit up in bed, and although we felt apprehensive we always expected him to get well. To my mind the small amount of shock and the quick recovery were almost entirely due to Berger's admirable foresight. He knew that to attain success hæmorrhage must be prevented by the preliminary ligature of the great vessels. It was not necessary to carry out Kocher's suggestion and try to tie the small transverse cervical and suprascapular arteries.

Next in importance comes the systematic division of muscles one by one, each vessel being secured, if possible, before division, but certainly the moment it begins to bleed. Not only does the prevention of hæmorrhage in these ways tend to minimise shock, but it also leaves the patient in infinitely better condition to make a speedy convalescence and to combat any complication which may ensue.

Although I especially inquired of my friend and colleague Mr. Richard Gill, who gave the anæsthetics, he was of opinion that there was no shock when the cords of the brachial plexus were divided.

In the next place we should note the rapidity with which the sarcomata grew and carried off the patients. In the instance of round-celled sarcoma of the scapula, which was of the most malignant nature, there was no occasion for surprise, but in the other of chondro-sarcoma of the scapula there was every reason to hope that the operation had extirpated the disease. But this and other instances have convinced me that a chondro-sarcoma is a far more malignant disease than is usually thought; that it is likely to recur at the place whence it had been removed, and to invade other parts of the body. We know the swiftness with which cancer invades the lymphatic system. My experience tells me that a rapidly growing sarcoma invades the lymphatic system almost as quickly, and the vascular system much more quickly—very strong reasons why every tumour should be at once exposed, microscopically examined, and surgically dealt with.

AMPUTATION AT THE HIP-JOINT.

I now propose to refer briefly to the cases of amputation at the hip-joint.

In recent works on operative surgery I cannot see that the principles which are so admirably fulfilled in Berger's operation have been systematically applied to amputation at the hip, otherwise we should not have to read accounts of ingenious, and in my opinion unnecessary, devices for the prevention of hæmorrhage. Amongst these various devices are steel pins for transfixion, steel rods, clamps, hæmostatic forceps, Esmarch's tourniquet, rubber tourniquet with transfixion steel pins to prevent it from slipping, a rubber tube pushed through the limb, and so forth. Such a multiplicity of devices is a sure indication that all is not well. In the following eight cases of amputation of the hip-joint the principles which govern Berger's operation have been carried out.

The operation has been begun by ligaturing the main vessels after emptying the limb of blood by holding it up. Then the flaps have been fashioned and the muscles cut through one by one, and each vessel secured either before division or the moment afterwards. In spite of the grave condition of some of the patients at the time of operation, and in spite of the formidable growths for which some of the operations were performed, all recovered from the operation, and in some the recovery was rapid. In a few instances not only was amputation done at the hip, but malignant glands were taken away from the iliac fossa or pelvic brim.

Even an enchondroma is not so innocent as is sometimes thought.

CASE 4.—A man, aged 47 years, had a hard oval swelling 4½ inches by 3 inches fixed to the left femur below and in front of the great trochanter. It was thought that this had been growing for a year. It was an ossifying enchondroma, and was removed by chiselling through its bony pedicle. The body of the tumour consisted of cartilage undergoing mucoid degeneration. Six years later (Feb. 13th, 1906) he was readmitted. A tumour had slowly grown at the site of the old operation. It was sufficiently large to prevent full flexion of the left hip-joint. The inguinal glands were large on both sides, but the left were by far the largest.

On Feb. 24th I performed an amputation at the left hip-joint. The incision was begun over the common femoral artery, which was tied and divided, also the common femoral vein, then all the lymphatic glands were removed from Scarpa's triangle and immediately examined. Those upon the top of the tumour had growth in them, but not those near the femoral canal. Amputation at the hip-joint was

then completed in the usual way, the muscles being cut one by one and every small vessel secured immediately. My note says that there was very little bleeding. The shock following the removal of the lower limb at the hip-joint of a muscular man aged 47 years was by no means excessive. The temperature fell to 96° F., and the pulse rose to 112 and the respirations 28. A speedy convalescence ensued. There was slight necrosis of the edge of the flaps, but this caused but little delay in the healing.

The pathologist reports that the tumour was a chondroma and with no evidence of sarcoma in it. But however this may be, it is to be noted that the tumour had grown again after a bony stalk had been cut through, and that it had invaded the neighbouring lymphatic glands. This patient is known to have been well (Nov. 28th, 1908) one year and nine months afterwards.

CASE 5.—Amputation at the hip-joint was performed upon a woman aged 39 years. She had a huge growth in the upper part of the right thigh, and enlarged lymphatic glands in Scarpa's triangle and in the iliac fossæ. Thus the operation consisted of two parts: first, the removal of the lymphatic glands; and secondly, of the limb. The growth is said to have been of six years' duration, and probably began in the soft parts.

On Nov. 23rd, 1906, an incision was made over the common femoral vessels, which were ligatured after the lymphatic glands had been removed. The iliac fossa was then exposed and several enlarged lymphatic glands removed from it. Although these glands were so much enlarged they are said by the pathologist not to have contained any growth. In spite of this I suspect that they would have continued to grow. The amputation was completed in the usual way and with hardly any hæmorrhage. The shock was comparatively slight, the temperature fell to 97·4° F., the pulse remained at 80 and the respirations at 28. My note says that the shock was about the same as might have been expected after the complete amputation of the breast with removal of the pectoral muscles. The wound healed by first intention. The amputation was performed on Nov. 23rd, 1906. The patient died from a growth in the thorax on June 8th, 1907. Six years is a long interval between the discovery of a tumour and its removal.

CASE 6.—Amputation through the hip-joint was performed upon a girl, aged 18 years, for a recurrent sarcoma of the femur. Six months before Mr. Butlin had amputated through the middle of the thigh for a tumour which the pathologist reported to be "a periosteal cystic sarcoma—mixed celled, with giant cell systems." On April 13th, 1897, amputation through the hip-joint was begun by an incision over the common femoral vessels, but a high division was found, so that the superficial femoral artery and vein were first tied and afterwards the deep femoral artery and vein. This anatomical peculiarity was easily recognised and gave rise to no difficulty. The remainder of the limb was then removed by lateral flaps and the wound was drained. Although there was but little hæmorrhage the shock during the course of the operation was severe. From beginning to end of anæsthesia it took one hour. There was great shock on division of the great sciatic nerve, and the patient had two injections of strychnine whilst on the table and afterwards saline injections. During the shock her temperature fell to 97° F., and the pulse rose to 108 and the respirations 24. However, a few hours afterwards a satisfactory reaction had taken place. For the shock which sometimes ensues when the sciatic nerve is divided may be severe at the moment but is not of long duration. The shock caused by hæmorrhage does not soon disappear because the vascular system has to be replenished. Also we may note that the previous removal of the lower limb from the middle of the thigh made no difference in the shock. This wound became infected with colon bacillus, although I had taken care to keep the incision as far away as possible from the anus and pudenda. However, it ultimately healed well. About ten months later, on Feb. 24th, 1898, Mr. Butlin removed some sarcomatous glands from the neighbourhood of Poupart's ligament, and 11 months later the patient died from a recurrence in the lung, having survived less than two years.

CASE 7.—Amputation at the hip-joint was performed under similar circumstances upon a boy, aged 11 years, who had had a tumour at the lower end of the femur. On April 2nd, 1907, the knee was explored by my colleague Mr. G. E. Gask, who performed amputation through the middle of the thigh. The tumour was a periosteal sarcoma of the lower end of the femur. The patient made a rapid recovery, but shortly afterwards some enlargement was observed in the lymphatic glands in the groin, and the end of the stump seemed suspicious.

On May 14th, 1907, I explored the end of the stump and found mixed-celled sarcoma. Next, the common femoral vessels were tied and the enlarged inguinal glands removed—they are supposed only to have shown inflammatory changes, but I am very doubtful about the microscopical diagnosis of sarcomatous glands. I believe that they are often infected, although the pathologist cannot determine the fact. Amputation at the hip-joint was then completed with very little shock and consequent small loss of blood. The sciatic nerve had an unusually large bulb at its cut end. During the shock the temperature was 97° F. and the pulse 120; during the reaction the temperature rose to 99·4° and the pulse to 120. He left the hospital five weeks afterwards for a convalescent home. Whilst he was at the convalescent home he is said to have had severe pleurisy, and he returned to his own home, where he shortly afterwards died.

This is another instance of the malignancy of subperiosteal sarcoma. The swelling at the lower end of the femur had been noticed six weeks before Mr. Gask's operation—a slight limp drew attention to it, so there was no unreasonable delay in this case.

CASE 8.—Amputation of the hip was performed upon a female aged 32 years. Some of the clinical features were unusual. There was a fluctuating swelling at the upper and outer part of the right thigh, which was thought to be a hæmatoma, but in addition the lymphatic glands in Scarpa's triangle and in the iliac fossa were much enlarged. The tumour had been growing for three years. The tumour swayed a little, and the superficial femoral vessels lay behind its inner side. The tumour was exposed and after the escape of a quantity of dark blood, probably liquefied clot, a portion of the surrounding growth was removed and found to be sarcomatous. The anterior crural nerve ran through it and the superficial femoral artery and vein could not be separated from its inner and posterior surface, therefore a large anterior flap was made; all the lymphatic glands were removed from Scarpa's triangle and from the iliac fossa, after which the femoral vessels were ligatured and the limb removed, the muscles implicated in the growth being detached from the pelvis. Very little blood was lost and shock was moderate and satisfactory reaction speedily ensued. So that it is possible to add a pelvic operation to amputation of the hip.

I was guilty of an error of judgment in this case. The wound looked so dry and altogether satisfactory that instead of putting in a proper drainage-tube a small gauze drain was used. This proved quite inadequate, for a hæmatoma formed and became septic.

The operation was performed on June 27th, 1905; by Sept. 27th of that year a growth could be felt fixed to the right side of the pelvis, and on Oct. 31st, 1905, the patient died from sarcoma of the pelvis. It is to be noted that the growth had been allowed to grow for three years.

The next two cases of amputation at the hip make an excellent contrast—they were both performed upon patients who were desperately ill and emaciated, after prolonged suppuration in and about the hip-joint. In the first the hæmorrhage was slight and consequently the shock was moderate. In the second, owing doubtless to the prolonged inflammation around the hip, there was more bleeding than usual, although in no way an excessive amount.

CASE 9.—A man, aged 46 years, had suppuration in the left hip for three years. There was a large abscess on the upper and outer side of the thigh. A photograph showed erosion of the head and neck of the femur and partial dislocation. A vertical incision was begun well to the outer side and the anterior flap turned upwards and inwards. The common femoral vessels were then secured and divided and the amputation completed in the usual way. The note says that the shock was slight, the temperature fell to 96·4° F., the pulse became 116, and the respirations 26. As some of the acetabulum was bare at the time of amputation a sinus persisted and convalescence was slow, but the ultimate improvement in the patient's condition was remarkable.

CASE 10.—Ten years ago amputation at the hip was performed upon a boy by Furneaux-Jordan's method for suppurative arthritis of the hip. I began by tying the common femoral artery and vein through a separate vertical incision. There was some bleeding from a branch which sprang from the back of the vein and which was transfixed by the aneurysm needle. However, the bleeding was easily controlled by pressure forceps. The amputation was then completed in the usual manner. The hæmorrhage was smart when the circular cut was made and also during the removal of the upper end of the femur. The subsequent shock was severe.

This does not contrast favourably with the operations done by slow and methodical division of the muscles and immediate restraint of hæmorrhage. This patient ultimately recovered and did well.

CASE 11.—Amputation at the hip-joint was also performed for a youth aged 16 years. He, too, had suppuration in and around the right hip. He was very anæmic and emaciated, with a persistently elevated pulse and temperature. On Dec. 19th, 1908, an abscess was opened and some thick pus escaped and staphylococcus pyogenes aureus was cultivated from it. But slight improvement ensued, and on Jan. 25th the wound was reopened and a quantity of inflammatory tissue with cancellous bone in it was removed from about the back of the neck of the femur. After this he improved for a while, but the swelling remained, and then his temperature became continuously high, so on April 13th, 1909, the sinus was again reopened and drained but with no good result.

On June 22nd amputation was performed at the hip. As the case was septic the common femoral vessels were tied with chromic gut, a separate vertical cut being made for the purpose. Some enlarged glands were with difficulty removed. My note says that the external circumflex artery and its branches bled freely. Owing to the brawny condition of the tissues it was difficult to restrain this as quickly as usual. Perhaps I could have done so if I had provided myself with toothed pressure forceps. Great shock ensued; his temperature fell to 96° F., the pulse became 116, and the respirations 28. As might have been expected, the wound suppurated and on Dec. 2nd, 1909, the boy left for a convalescent home, markedly improved in every respect, but there was still a sinus.

This case had, to my mind, a singular feature about it. The tissue which was removed, and which was called inflammatory tissue with cancellous bone in it, looked like an ossifying sarcoma, and in spite of the suppuration I have never felt sure that this was not the case. A skiagram taken before the boy left the hospital showed a large shadow filling up the acetabular region, and the stump was enlarged and very hard.

Eight cases of amputations at the hip-joint have now been given, and fortunately all have recovered from this formidable operation. I have not met with that hæmorrhage from the obturator, gluteal, or sciatic vessels which some speak of. Vessels of any size can be seen and secured before they bleed.

AMPUTATION AT THE SHOULDER-JOINT.

Impressed by the lessening of shock and speedy reaction in most of these amputations at the scapula and at the hip, and which, in my opinion, was due to the care taken in preventing bleeding, one naturally extended the same principle to other amputations.

CASE 12.—On Jan. 21st, 1908, amputation at the shoulder-joint was performed upon a man, aged 56 years. In addition to a periosteal sarcoma in the lower half of the left humerus he had osteitis deformans with characteristic changes in his skull and long bones. It is probable that the tumour had been growing for 15 months and had attained a considerable size. A fresh section confirmed the clinical diagnosis. The amputation was performed at the shoulder-joint by a method which is practically the same as that of Spence, but as a preliminary an incision 6 inches long was begun over the tip of the coracoid process and carried through the tendon of the pectoralis major. This brought in view the axillary vessels, which were tied above and below and divided. Then the brachial plexus was cut though without additional shock, and the amputation was completed in a leisurely fashion, the vessels being secured either before division or the moment they were met with. There was very little bleeding and consequently slight shock. After the operation the temperature merely fell to 97° F., the pulse being 76. The wound healed by first intention and a rapid convalescence ensued.

I am informed that within a few months this patient died from a recurrence of the growth in the spine. It is much to be regretted that the tumour had not been explored months before. A frozen section would have cleared up every doubt.

CASE 13.—Amputation at the shoulder-joint was performed in the same way upon a woman, aged 23 years, a domestic servant, for a subperiosteal sarcoma of the upper end of the left humerus. The operation was performed on April 17th, 1900. The incision was begun at the tip of the coracoid process and carried down the arm. After division of some of the fibres of the deltoid the axillary artery was tied. Next some sarcomatous glands were dissected out of the axilla. Then the incision was carried outwards and backwards through the deltoid because the tumour had grown into its lower part. Owing to the size of the tumour a part of the acromion process had to be sawn through to enable me to open the shoulder-joint and disarticulate. The size of the tumour was such that it had grown up against the acromion process. My note says that in the course of this operation the patient might have lost 2 ounces of blood. During shock the temperature was from 97° to 98° F. and the pulse was 88. During the reaction the temperature rose to 99·6° and the pulse to 114—that was the highest temperature. The pulse rapidly fell. The wound healed by first intention and the patient was discharged before the end of the third week.

This patient died on August 9th, 1903, about three years and five months after the operation. Eighteen months before her death it is said that an operation was performed at Cardiff for an internal tumour, but afterwards she had, I am told, tumours all over her body.

CASE 14.—Amputation at the shoulder-joint was also performed on a woman, aged 65 years, on July 9th, 1909, for gangrene which had begun on June 13th. When the amputation was done the gangrene had almost reached the middle of the arm. When the artery was exposed it was thrombosed. There was very little shock—the temperature fell to 97° F., the pulse rose to 120, and the respirations to 32. The wound healed by first intention.

AMPUTATION THROUGH THE NECK OF THE HUMERUS.

The advantage of ligaturing the main artery was shown in the following case of amputation through the neck of the humerus.

CASE 15.—A man, aged 62 years, on Oct. 27th, 1908, had amputation performed through the surgical neck of the humerus. He had an epithelioma on the back of the wrist which had been growing for seven years, but more quickly during the last two. It had been ineffectually treated by X rays and by zinc ionisation. There was considerable enlargement of the supra-condyloid gland, also suspicious fulness along the brachial vessels. The axillary glands were a little enlarged.

The usual incision was made beginning at the tip of the coracoid process and carried down about 6 inches. The axillary glands were taken away but contained no growth. Next, the cords of the brachial plexus were cut short and the brachial artery and vein were tied and divided. It seemed wise to remove as much as possible of the lymphatics, many of which are so close to the nerve trunks. The arm was then removed at the surgical neck of the humerus. There was very little loss of blood and consequently little shock, the temperature merely falling to 97° F., the pulse being 76. During reaction the temperature rose to 100° and the pulse to 100. Slight necrosis of the skin edge of the flap, which was associated with the colon bacillus, delayed union. But he went to our convalescent home in less than a month (on Nov. 24th, 1908). This man died on Jan. 21st, 1910, the primary cause of his death having been certified to be bronchitis and the secondary morbus cordis.

In other amputations lower down the arm the main vessel is so easily controlled, even by the operator himself, that the previous ligature of the brachial vessels is not of great advantage. Nevertheless, I have of late begun by exposing and tying them. In the case of a child they were exposed, clamped, and tied, the ligature being put on afterwards.

AMPUTATIONS THROUGH THE THIGH.

To anyone in the habit of ligaturing the main vessels before amputating at the hip and shoulder it is but natural

to take a further step. I have never felt satisfied with what has hitherto been done to control hæmorrhage during amputations through the thigh. These have oftentimes to be done under desperate circumstances and when it is of the greatest importance to avoid loss of blood. Even a moderate loss of blood may extinguish the chances of one who is dying from diabetic gangrene. Those who are emaciated and weakened by long-continued tuberculous or septic arthritis of the knee are ill fitted to bear much loss of blood. If the immediate shock is overcome the reaction is tardy, and the exsanguined patient is not likely to make a speedy recovery or combat complications which may ensue.

The steps usually taken to control hæmorrhage during amputation through the thigh are not, to my mind, at all satisfactory. Am I singular in feeling distrustful of digital compression? Of digital compression of the subclavian artery Mr. F. F. Burghard says it "is an uncertain method at the best."[3] Once I failed to compress the external iliac artery and felt deeply humiliated by the failure. Compression was difficult because of some enlarged glands, and the fingers slipped when the limb was jerked up. More than once I have seen digital compression fail. Considerable loss of blood has invariably ensued. Others, too, seem distrustful of digital compression, otherwise we should not have had such a multiplicity of tourniquets. Those made of steel seem to have disappeared since the introduction of Esmarch's elastic band. But that has always seemed to me rather a crude, unsurgeonlike device. The wheal which it may make is unpleasant, and such pressure cannot always be good for the underlying artery and vein. May not thrombosis follow its use? Why should the skin flaps at times mysteriously die?

CASE 16.—A man, aged 66 years, had gangrene of the left foot. The anterior tibial artery could be felt pulsating, but a skiagram showed that it was calcified, and also the posterior tibial; the arteries generally were hard and tortuous. On March 9th a surgeon amputated through the upper third of the leg. An elastic tourniquet was put on just above the knee. By March 25th the flaps were gangrenous, with severe pain and septic absorption.

On March 26th I again amputated through the lower third of the thigh, the artery being exposed and tied forthwith. There was comparatively little shock. Owing to the infection of the cellular tissues of the thigh at the time of the operation the stump suppurated, but ultimately healed after further removals of femur. The patient left the hospital at the end of July with the wound healed.

The risks of amputating through the upper third of the leg when the vessels are calcareous are well known, but elastic pressure upon such vessels must be attended with danger, and it seems to me reasonable to suppose that in the instance just given that may have had something to do with the gangrene of the flaps. If the surgeon elects to amputate in the upper third of the leg when the arteries are known to be calcareous, it would, in my opinion, be wiser to plan the amputation so as to tie the tibial and peroneal vessels before completing the flaps, thus avoiding compression of the main artery and vein.

The troublesome and persistent arterial bleeding which takes place after the removal of the elastic band is one of its most objectionable features. This is mentioned in most recent works on surgery, but they do not suggest any practicable alternative.[4] The long-continued elastic pressure seems to paralyse all the small arteries, especially the muscular ones. So that of late, taught by my experience of amputation at the hip and shoulder, I have begun amputation through the thigh with an incision over the superficial femoral vessels, so as to be able to tie them at the level of the sawn end of the bone. Afterwards the flaps have been slowly made with a small knife, each small vessel being instantly clamped. The following are examples of advantages of this simple proceeding.

CASE 17.—On Oct. 10th, 1909, amputation was performed through the left thigh of a man, aged 56 years, for advanced tuberculous arthritis of the knee. The disease had been in progress for two years; the pain was very severe. The man was emaciated, and in addition to tubercle of the knee had tubercle of the right lung. An incision was made at the lower end of Hunter's canal and the femoral vessels were ligatured and divided as they entered the popliteal space. The amputation was then completed in the usual way, any bleeding point being at once secured. There was very little loss of blood and consequently little shock. The wound healed by first intention and the patient left the hospital 24 days after the operation.

The improvement in the patient's condition was very marked, and we all agreed that he did very much better than such cases usually do, and which I attribute to the avoidance of hæmorrhage during the operation.

Everyone, I am sure, dreads having to amputate the thigh in cases of diabetic gangrene, for that operation is attended by a very high rate of mortality. I doubt whether the following case of amputation through the thigh for diabetic gangrene would have recovered had it not been for the immediate ligature of the main vessels.

CASE 18.—The patient was 64 years of age and had 4 per cent. of sugar in the urine. For many weeks some of his toes had been gangrenous. Latterly the heel had become affected and the leg was threatened. Septic absorption was taking place, the temperature was usually well over 100° F., and the pulse at least 120. His lips and face were rather livid and at times he was drowsy—altogether a forbidding state of affairs.

The operation was begun with the patient lying comfortably upon his back. The vessels were exposed at their exit from Hunter's canal. The artery and vein adhered so closely that rather than spend time in separating them they were both included in a single silk ligature. Without moving the patient the amputation was completed in a leisurely manner, the muscles cut through with a small knife, and each bleeding vessel secured at once. Very little blood was lost and my friend Mr. Gill tells me that he noticed no shock. Owing to the diabetes and the condition of sepsis the patient remained gravely ill—the pulse sometimes ran up to 130 and was intermittent. Strychnine and strophanthus certainly improved the heart, but the greatest benefit was obtained from the continuous inhalation of oxygen. This was continued day and night for many days. The stump healed by first intention and the patient was able to return to his home about three weeks after his operation. The relief was, I fear, but temporary.

I cannot help contrasting this case with another of almost exactly the same kind which was operated upon by the methods which I have now discarded.

CASE 19.—The patient, a lady of mature years, suffered from diabetes and had 5 per cent. of sugar in the urine. One day she applied some strong acid to a corn, and gangrene of the foot ensued. An assistant undertook to control the artery with his fingers. The amputation was performed through the thigh. When the vessels were divided there was for a moment smart hæmorrhage which was speedily controlled. In other circumstances the loss of blood might not have mattered, but the patient is said never to have recovered from the shock, and died within 24 hours. How much better it would have been for the surgeon to have had the hæmorrhage entirely within his own control.

Although my experience of ligaturing the main vessels of the thigh before performing amputation is so small, yet the results have been so admirable that I shall now continue to do so, and I trust that others will follow my example.

[3] Loc. cit., p. 146.

[4] E.g., Burghard in a System of Operative Surgery, 1909, at p. 248 refers to the well-known persistent paralytic oozing after its removal.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.

The usual monthly meeting of the executive committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on April 15th. There were present: Dr. F. de Havilland Hall (in the chair), Mr. J. Brindley James, Dr. F. C. Martley, Dr. J. W. Hunt, Mr. F. S. Edwards, Dr. Frederick S. Palmer, Dr. St. Clair B. Shadwell, Dr. F. J. Allan, Mr. J. F. Colyer, Dr. W. Knowsley Sibley, and Dr. J. B. Ball. The accounts presented show that the business of the society has been exceptionally good during the first three months of this year. The number of claims received has been less than usual, and with few exceptions they have been of short duration. The committee examined the draft of the report for the year 1909 to be presented to the members at the annual general meeting on May 19th next. A large increase is shown in the invested funds which now amount to nearly a quarter of a million sterling, while the sum paid away as sick benefit reached the record amount of £15,115, although the sickness experience was less than that expected and provided for in the tables. Prospectuses and all particulars may be obtained on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

FURTHER WORK ON THE PRESSOR BASES OF THE URINE.

BY WILLIAM BAIN, M.D. DURH., M.R.C.P. LOND.

(*From the Physiological Laboratory, King's College, London.*)

IN a paper published in THE LANCET last year [1] I showed that the urine contains certain bases which originate from putrefactive processes in the intestine. When injected into the blood stream they produce a marked rise of arterial blood pressure. Abelous previously had extracted from the urine a mixture of pressor bases, which he called "urohypertensine," but which he did not identify. I suggested that the retention of these bases in the body might be an important factor in raising the arterial pressure, and this view was supported by the examination of the urine of a few patients with increased blood pressure. In each of these cases the bases were either absent from the urine or present in greatly diminished quantity.

During the past few months I have continued the investigation, and examined in all 32 urines, but only the more interesting ones in the series will be alluded to in this paper; several urines were obtained from normal subjects and these served as a control. The result of this work has been to confirm my main conclusion in reference to cases of high blood pressure; I have also come across several new points of interest which demand fuller investigation in the future.

Methods.—In extracting these bases from the urine it is of paramount importance to obtain a trustworthy method. In my previous paper I described the original method of Abelous and several modifications of it. The simplest of these is what I spoke of as the "direct method"; without going into details again, this consists in extracting the urine with ether, and subsequently with amylic alcohol. One of the bases, which may safely be assumed to be iso-amylamine (a derivative of leucine) on the evidence previously adduced, is present in the ethereal extract. The amylic alcohol extract contains another base which is probably *p*-hydroxyphenylethylamine (a derivative of tyrosine), and which is the more active of the two in raising the blood pressure. There are probably other bases in the crude extracts (see later).

The disadvantage of the direct method is that in certain urines thick emulsions are formed when the urine is shaken with the extracting agents, and these are exceedingly difficult to separate satisfactorily. As the emulsions are probably due to the presence of colloid substances, it was hoped to remove them by treating the urine with certain substances which are known to adsorb colloids. The first of these which I tried was kaolin (4 per cent.); this did not entirely abolish the emulsion formation, although the emulsions were less dense than when the kaolin was omitted. The rises of blood pressure obtained after this method of treatment were not so marked as with the same urines treated by the direct method. It is thus evident that kaolin adsorbs not only most of the urinary colloids but some of the pressor bases as well.

Three varieties of charcoal were then obtained: (1) bone charcoal (Kahlbaum); (2) charcoal of unknown origin (Heller's); and (3) blood charcoal (Fleming's first quality). 4 per cent. of bone charcoal generally prevented the formation of emulsions without decolourising the urine completely, but, like kaolin, adsorbed a small portion of the bases. 2 per cent. of Heller's charcoal completely decolourised the urine, but did not prevent emulsions being formed. 4 per cent. of Fleming's blood charcoal both decolourised the urine and completely prevented the formation of emulsions. There was, however, no trace of the bases in the filtrate; they had been entirely removed by the charcoal. On Dr. O. Rosenheim's suggestion, the use of this charcoal, which at first sight seemed to defeat my main object, really afforded me the easiest method of obtaining the bases, for they can readily be extracted from the charcoal by boiling it with dilute hydrochloric acid. Not only is this charcoal method the easiest, but it is probably the most trustworthy.

In each experiment, as in those previously recorded, I worked with the same amount of urine—namely, 2½ litres. The charcoal is first vigorously shaken up with the urine for about 15 minutes and the mixture filtered. The filtrate ought to be colourless. The residue on the filter is then transferred to an evaporating basin and boiled with dilute hydrochloric acid and filtered. The filtrate containing the whole of the bases is made alkaline with sodium hydrate, and extracted with ether six times. It is then reacidified with hydrochloric acid, and having been made alkaline with powdered sodium carbonate is extracted with amylic alcohol twice. If the ethereal and amylic alcohol extracts are not quite clear they should be filtered, the latter through cotton-wool in a pressure filter. Both the extracts are then extracted with dilute hydrochloric acid. The hydrochloride solution is carefully concentrated in a small capsule on the water bath, and excess of the acid removed by leaving the capsule in a desiccator containing soda-lime. The residue is taken up with normal saline solution, and after neutralisation made up to 6 cubic centimetres. A specified portion of this (in most of my experiments 3 cubic centimetres) was injected intravascularly. The animals used for the experiments on blood pressure were cats, the injection being made into the external jugular vein; the arterial pressure from the carotid artery was registered in the usual way with a mercurial manometer. The animals were either anæsthetised with ether, or had been previously pithed under anæsthesia, and then kept alive by artificial respiration. I distinctly prefer the pithed animal as the effect upon blood pressure is much more marked than in those which are anæsthetised.

Influence of age.—Among the normal urines I examined a year ago was that of a boy aged 13 years, and I was surprised to find the almost complete absence of pressor bases; the amylic alcohol extract gave a faint rise of pressure, but the ethereal extract gave none whatever. I subsequently found the bases absent in the urine of another boy aged 14 years, and in the case of a lad aged 16 the rises were infinitesimal. The urine from a young man of 19 gave distinct rises with both extracts, but much smaller ones than were obtained from the urines of six normal adults varying in age from 26 to 54 years. This influence of age on the formation of pressor bases I intend to follow up more fully; the few experiments I have so far done certainly suggest that the absence of these bases from the urine of young people is one of the characteristics of this period of life.

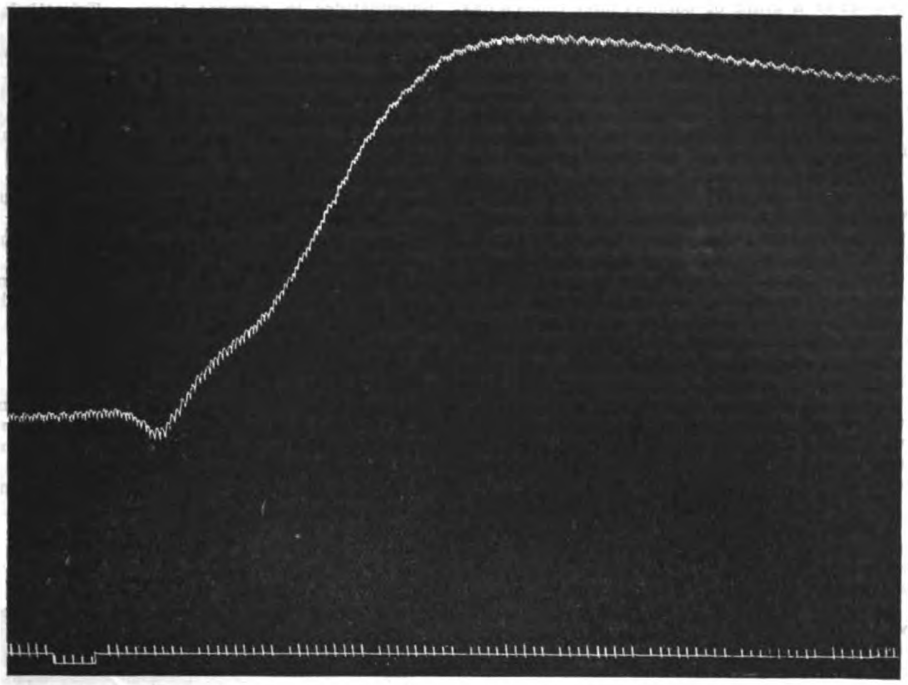
Cases of high blood pressure.—I have had the opportunity of examining the urines of three cases of high blood pressure.

1. This was from a gentleman, 74 years of age, with a systolic blood pressure of 200 mm. Hg. The urine was of normal specific gravity and was free from albumin. Three years ago his pressure was 260 mm., but dieting brought it down. The ethereal extract produced no rise of blood pressure, and the amylic alcohol extract only a slight one.

2. This was from a lady, 50 years of age, with a systolic blood pressure of 180 mm. Hg. The urine was of normal specific gravity and was free from albumin. She was slightly gouty. The effect on blood pressure was practically the same as in the first case, and the experiment was done upon the same pithed cat.

3. This was urine obtained from one of Dr. F. W. Mott's patients; the blood pressure was "very high," but I have not the actual figure. The urine contained albumin. Both bases were entirely absent.

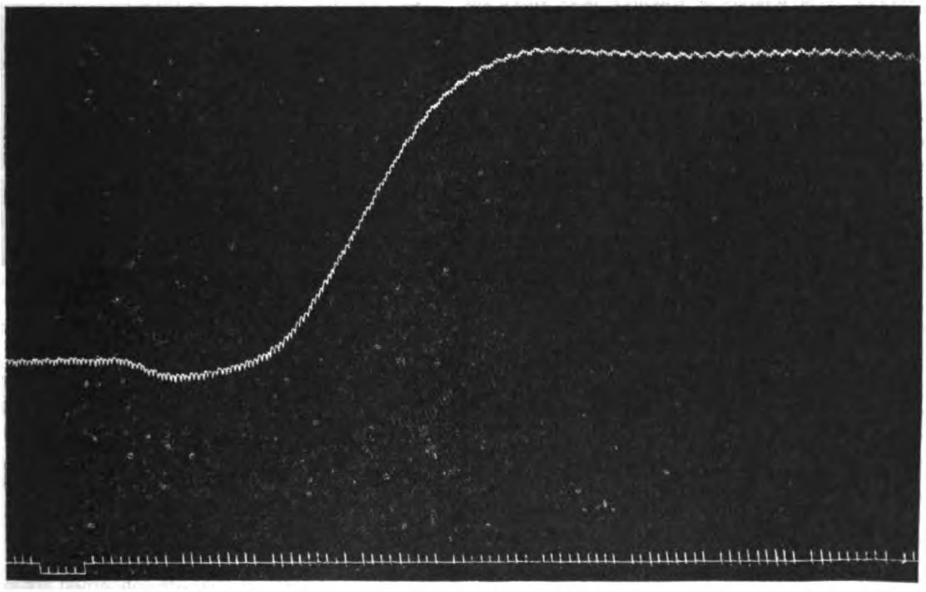
Cases of gout.—Here I have only two cases to record.



1. The patient was subject to repeated acute attacks of gout; the blood pressure was 135 mm. Hg. The experiment was performed upon the same animal as was used in the investigation of the urine of a normal adult with a blood pressure of 125 mm. Hg. The rises of pressure in the gout case were only about half those obtained with the extracts of normal urine prepared in exactly the same way.

2. This patient was a gentleman, 60 years of age, who had marked gouty deposits, but he had never had an acute or subacute attack; this was, therefore, quite a different type of the disease. His systolic pressure was only 98 mm. Hg; the amylic alcohol extract gave the normal rise, but the ethereal extract produced a comparatively small one.

Effect of diet.—The effect of diet is obviously a branch of the investigation which can be almost indefinitely extended, and I hope to be able to do more work in this direction in the future. It demands the most careful study in reference to the origin of the pressor bases. The factors I have so far investigated were the influence of (1) meat diet; (2) meat diet *plus* antiseptics; and (3) milk diet.



[1] THE LANCET, August 7th, 1909.

FIG. 1.

Blood pressure tracing from pithed cat taken from the carotid artery. This and the succeeding tracings are to be read from left to right. The time tracing marks seconds and is placed in the position of the abscissa of the blood pressure. The lowering of the level of the time tracing near the left hand end marks the period during which an injection was made into the external jugular vein. The material injected was a saline solution of the pressor base, which is soluble in ether, and the amount injected (3 cubic centimetres) represents the yield from 1250 cubic centimetres of normal urine.

FIG. 2.

This is a similar tracing obtained from the same cat. The injection here made was a saline solution of the base which is soluble in amylic alcohol, and again represents the amount obtained from 1250 cubic centimetres of urine. In this, as in the preceding tracing, the method used was the "charcoal method" described in the text.

Two subjects were placed upon a diet of meat, green vegetables, and a small quantity of bread for three days, during which time 2½ litres of urine were collected from each. They then continued for another period of three days to take the same diet, but received in addition 10 grains of salol and a quarter of a grain of calomel three times a day. Another 2½ litres of urine were collected during this period. They then each took a dose of magnesium sulphate preparatory to being placed on a diet of milk and biscuits (Huntley and Palmer's breakfast biscuits). During this third period of three days they had also every day half a pint of lacto-bacilline milk, and 2½ litres of urine were again collected. These urines were all examined by the older "direct method," as at that time I had not the advantage of knowing the "charcoal method."

As the general result it may be stated that the formation of the pressor bases was not influenced by these variations in the diet. The disinfectants in the doses administered had no effect in reducing the amount of the bases excreted. This fits in with previously recorded experiments, in which it has been shown how slight is the effect on intestinal putrefaction of medicinal doses of disinfectants given by the mouth.

The similar negative effect of a milk diet even in the presence of lactic acid bacilli is also interesting and shows that the bases in question can originate from casein. This was confirmed by an experiment with putrefying casein, which was treated in a similar manner to the urines. Both the ethereal and amylic alcohol extracts of this material produced pronounced rises of blood pressure when intravenously injected.

Intestinal putrefaction is no doubt largely inhibited by a milk diet, and this effect is now generally attributed to the carbohydrates present which favour the development of lactic acid bacteria, which in their turn inhibit the typical putrefactive organisms. Casein as such is not responsible for the prevention of putrefaction, as was shown by the experiment just alluded to which I performed with putrefying casein free from carbohydrates.

The fact that the pressor bases were present in the urine during a milk diet suggests that they are formed in the lower part of the intestine where the growth of the putrefactive organisms is less restricted, owing to the removal of the carbohydrates by absorption in the upper portion of the intestinal canal.

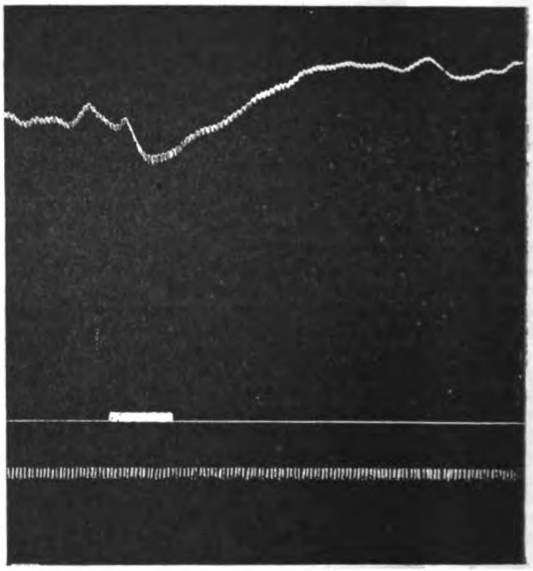
The remainder of the 32 urines at my disposal need not be referred to; they were mainly employed in the experiments I performed while elaborating my new method of isolating the bases.

I have selected from numerous tracings only three for reproduction to illustrate special points. Figs. 1 and 2 show the normal effect with the two extracts prepared by the "charcoal method." Fig. 3 shows the greatest effect with the amylic alcohol extract I have ever obtained from a case of distinctly high blood pressure (the lady 50 years of age previously mentioned). In no case of high blood pressure have I ever obtained any rise at all with the ethereal extract.

In conclusion, there are two side issues of my work that strike me as interesting.

1. I noticed in the urine of the case of gout with low blood pressure that scarcely any emulsion formed on shaking it with ether or amylic alcohol; this urine also contained a large deposit of uric acid. Urines which deposit uric acid are generally pale in colour, and the absence of emulsion when shaken with ether points to a diminution of the urinary colloid.[2] The nature of the colloid matter in urine is only imperfectly known, but it always contains sulphur in ethereal combination, and there is reason to assume that it is either chondroitin sulphuric acid or some derivative of this compound. Chondroitin sulphuric acid is the characteristic sulphur-containing constituent of cartilage, and the frequency of gouty deposits in cartilage is usually assumed to be due to some affinity between uric acid and this tissue. The disordered metabolic state which underlies the gouty state may upset the normal course of sulphur metabolism in cartilage, and certainly the condition of the urine just referred to is very suggestive in this relationship, although the exact mechanism at play is still an unknown quantity.

2. In addition to the bases which I have investigated, trimethylamine must be mentioned as a constant though small constituent of urine. Its amount has been shown to vary with diet,[3] but derives special interest as a product of metabolism. In cases of nerve degeneration its amount is increased[4]; in this case it no doubt originates from choline, and from similar bases derived from the breakdown of certain phosphatides in nervous tissue. Trimethylamine can be readily estimated in urine, and this is another subject which requires following up. The trimethylamine would probably be contained in my ethereal extracts mixed with isoamylamine. Some observations previously made in this laboratory in a different connexion showed that trimethylamine raises the blood pressure. This observation I was able to confirm, and trimethylamine must therefore be added to the list of pressor bases. Since doing this, I find that Abelous, who has performed the same experiment, obtained a similar result.[5]



Conclusions.—The results of the research may be briefly summarised as follows:—

1. The pressor bases which are present in the urine of normal adults can be most readily obtained by shaking the urine with Fleming's blood charcoal, and subsequently extracting the charcoal with suitable reagents.

2. The urine of growing children contains these bases in minimal amount.

3. So far as the influence of diet is concerned, very little can at present be stated. In the two cases investigated, the substitution of a milk and biscuit diet for one rich in meat makes but little difference. Medicinal doses of antiseptics administered by the mouth do not make any appreciable difference in the amount of these products of protein putrefaction which is excreted in the urine.

FIG. 3.

This is the greatest rise of blood pressure similarly obtained in a cat produced by the amylic alcohol extract which I have ever obtained from a case of high pressure. The very small result contrasts very markedly with the large rise seen in Fig. 2. The amount of urine represented by the injection was the same in both cases. Ethereal extracts give no rise whatever. In this experiment the abscissa is drawn separately from the time tracing; the period of injection is indicated by a thick mark on the abscissa line.

4. In all cases of high blood pressure hitherto examined the urine contains very little of the bases in question, and in some cases they are altogether absent. The non-elimination of the bases probably indicates that they are retained within the body and play an important part in the production of the high pressure.

5. So far as cases of gout are concerned my materials have

[2] The relationship between urinary colloid and the solubility of uric acid is also noted in a paper just published by L. Lichtwitz, Zeitschrift für Physiologische Chemie, Band lxiv., p. 144, 1910.

[3] F. de Filippi: Zeitschrift für Physiologische Chemie, Band xlix., p. 433, 1906.

[4] K. Bauer: Hofmeister's Beiträge, Band xi., p. 502, 1908.

[5] Abelous and Bardier: Comptes rendus de la Société de Biologie, vol. lxvi., No. 11, 1909.

been rather scanty, and so any conclusions that may be formed must be taken with reserve. I scarcely think that there is any direct relationship between gout *per se* and the retention of the pressor bases, and yet in most cases which I have examined the diminution in the excretion of these bases is not proportional to the increase of arterial pressure observed; for example, the patient with a systolic pressure of 135 mm. Hg excreted about half the usual quantity found in normal urine, as judged by the intensity of the physiological effect.

6. In cases where the urine contains a deposit of uric acid there is a marked diminution of the colloid matter of that fluid. This colloid consists of or contains a sulphur compound—chondroitin sulphuric acid—which is a constituent of cartilage. The association of this condition with the frequency of urate deposition in cartilage is suggestive, and deserves fuller investigation.

I have great pleasure in acknowledging my indebtedness to Professor W. D. Halliburton for the use of his laboratory during my work and for his help in the blood pressure experiments, and to Dr. Rosenheim for his courtesy and suggestive aid during the investigation. To Dr. Mott and Dr. J. C. Muir I tender my cordial thanks for the specimens of urine which they have sent to me.

Harrogate.

THE OBSTRUCTION OF THE ILEUM WHICH DEVELOPS IN CHRONIC INTESTINAL STASIS.

BY W. ARBUTHNOT LANE, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO GUY'S HOSPITAL AND SENIOR SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

IN describing the causation, pathology, and treatment of chronic intestinal stasis I have illustrated and explained the changes in the appendix and ileum which arise in consequence of the progressive descent of the cæcum into the pelvis which takes place in this condition. In this communication I wish if possible to accentuate especially the change in the ileum in order to call attention to it in a more definite manner. I do so because it is most important and far-reaching in its influence for harm, and it has apparently not attracted the attention of any of the readers of my papers.

The cæcum loaded up with its fluid contents tends in the erect posture of the trunk to glide downwards and inwards into the true pelvis, which it struggles to occupy, together with the transverse colon and sigmoid, not only to the disadvantage of these structures themselves but also to the distinct detriment of the organs which exist normally in it. The mere hypertrophy of the muscular wall of this portion of the large bowel is insufficient to meet the excessive fluid pressure exerted upon it, and it gradually dilates and descends from its normal position. This tendency to falling of the distended cæcum is met by the formation of two series of resistances which develop as independent bands or thickenings in peritoneum. The thickening in the peritoneum is the first step from which the separate band or mesentery is subsequently developed.

The external series of peritoneal adhesions, bands, or mesenteries extends from the outer aspect of the cæcum upwards and outwards to the peritoneum lining the abdominal wall external to it (see Figure). The lowest of these not infrequently attaches the appendix, securing it in the first instance at its base and extending a variable distance along its length. In this manner the fixed portion of the appendix forms part of one of the ligaments or ties opposing the downward displacement of the cæcum. The result of strain exerted upon the appendix when the cæcum is full is to kink the distal mobile portion of the appendix upon that part which has taken on the function of a ligament and to partly or completely obstruct the lumen of its mucous lining. Such obstruction produces an accumulation in the distal portion of a transient or permanent character, and a condition which is described generally as appendicitis. In some cases a mass or concretion develops from the accumulated inspissated contents.

The other limb of the parallelogram of forces lies internal to the cæcum, and is an added strain along that portion of the mesentery which holds up the end of the ileum. In consequence of this strain a thickening forms on the under surface of the mesentery, and this contracts the mesentery along the line of strain. This exerts a drag upon the ileum at a point about two inches from its termination. In this way that piece of the ileum external to the area of thickening in the mesentery, together with that same thickening, form an internal resistance which holds up the dilated cæcum heavy with fluid contents and opposes its downward displacement. Therefore the last two inches of the ileum beyond the new band performs in addition to its normal function that of an internal ligament of the cæcum, precisely in the same way as the fixed portion of the appendix with the band securing

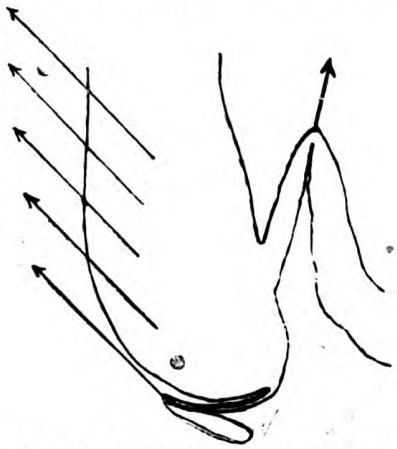


Diagram indicating peritoneal adhesions opposing the downward displacement of the loaded cæcum. The last adhesion is attached to the appendix.

it forms an external ligament of the cæcum. Again, as in the case of the appendix, the strain exerted upon the fixed portion of the ileum serves to reduce the calibre of its lumen and to produce an obstruction to the passage of fæcal matter through which it is damming back the material in the small intestine. This fæcal accumulation remaining for an abnormally long period itself undergoes changes and produces alterations in the intestines, which are experienced as discomfort, pain, or distress to the patient.

Clinically a varying degree of impairment of the function of the appendix is frequently associated with a similar defect in the end of the ileum. It is by no means necessary that the conditions should be associated, since the appendix may escape the grip of these newly formed peritoneal ties even in advanced cases of intestinal stasis. In proportion, however, as the appendix escapes performing its share in restraining the cæcum from getting too far into the pelvis, the greater is the proportion of strain thrown on the affected mesentery of the ileum and the more likely is this tube to be constricted by thickenings or bands. As indicated before, all these ties are represented in the first instances as thickened lines on the peritoneum and later as mesenteries free from the peritoneum to which they were originally attached. The skeleton represents a crystallisation of lines of force which when transmitted in one direction are laid down as compact tissue and when in varying directions as cancellous tissue. In precisely the same way the peritoneal thickenings and the bands or mesenteries into which they develop later represent the crystallisation of lines of strain and are evolutionary and functional, and have no relationship whatever with any inflammatory process.

The symptoms produced by the kink in the ileum are quite distinct from those which result from trouble in the appendix. They may be, and often are, associated, being produced by the same cause. The tenderness of the kink in the ileum extends from the umbilicus almost directly downwards and to the right, and is quite separate from the pain and tenderness of a fixed appendix. The distension of the small intestine is a marked feature and varies greatly with the time of day, since it is much worse when the abdominal wall is lax and tired. The pain develops or becomes accentuated at a more or less regular interval after the ingestion of food. It is increased by any jerky movement, as riding, running, especially up or down stairs, &c.

This kinking of the ileum is the cause of much of the pain

and discomfort that remains after the removal of the appendix. If the appendix has also been in trouble the pain and tenderness produced by it will have been removed by the operation, but the pain consequent on the kinking of the ileum still remains and is the cause of much disappointment both to the surgeon as well as to the patient. I would call the attention of the profession to the importance of this condition.

Cavendish-square, W.

SIGMOIDITIS AND MESO-SIGMOIDITIS.

BY R. P. ROWLANDS, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON, GUY'S HOSPITAL, LONDON.

DURING the last 18 months I have met with two interesting examples of this comparatively rare condition. They seem to me to be of sufficient interest and importance to merit publication, especially as the disease, particularly in this country, has not received the attention it deserves, with the result that it is often mistaken for malignant disease. The clinical symptoms and physical signs may closely simulate those of carcinoma of the sigmoid colon. It is very difficult to distinguish the two conditions even when the abdomen is opened. In at least 12 of the 25 instances of stenosis collected by Telling, a diagnosis of carcinoma was made either before or at operation. The true nature of the disease may be realised only after resection or even after microscopic examination. When the extent of the "growth" or the condition of the patient in the presence of acute obstruction does not allow a radical operation, the mistake may not be discovered. The unusual prolongation of life after colostomy or the spontaneous disappearance of the "growth" may give an indication of the true state of things. Most of us know of several instances of this kind. The writer knows of at least three patients who have survived for many years after colostomy for supposed carcinoma of the pelvic colon. Dr. W. H. Maxwell Telling in his able paper upon Acquired Diverticula of the Sigmoid Flexure [1] has pointed out that several museum specimens long regarded as examples of carcinoma of the sigmoid are really inflammatory. He draws special attention to one of the most important causes of simple inflammation of the sigmoid flexure, "the presence of acquired diverticula in or near the sigmoid colon."

It is very easy to overlook these diverticula, especially when they are limited to the mesenteric border. They project into a greatly thickened mesentery, and their orifices are often so small that they can only be discovered by means of a probe. They are so hidden that they can be very easily overlooked. The writer would certainly have overlooked them if he had not previously read Dr. Telling's paper. They are especially common at the mesenteric border following the blood-vessels, where the muscular wall of the bowel is often deficient and ill supported. The retention of irritating and infective material in the diverticula may lead to inflammation and even to perforation of the thin-walled sacs. This may be followed by spreading or localised peritonitis, but when the diverticula are deeply embedded in a thick mesentery the inflammation may be confined to the mesentery and the outer walls of the bowel. In some cases suppuration may take place between the layers of the mesentery, and pus may discharge into the bowel or into a diverticulum. In some it may burst into the peritoneal cavity. In many cases appendicitis may be closely simulated except that the swelling is on the wrong side. Sometimes the inflammation is more chronic and leads to much thickening and shortening of the mesentery and interstitial inflammation of the intestinal wall with secondary stenosis. The mucous membrane may remain fairly healthy for a long time. The condition is by no means limited to the sigmoid colon. Thus in one of my patients it extended from the pelvic colon to the splenic flexure. In others it has been limited to the splenic flexure or to a short segment of the transverse colon. The formation of diverticula in the colon seems to be chiefly due to long-continued constipation associated with failure of the muscularity of the intestinal wall. It is therefore a condition which is not often seen before middle age, and Telling points out that "the average age of those in which the diverticula caused clinical symptoms was 55 years" (47 cases). It is, of course, admitted that the presence of diverticula is not the only cause of inflammatory stenosis of the large intestine. Tuberculous infiltration, especially of the cæcum and ascending colon, may closely simulate malignant disease. Gonorrhœal, syphilitic, and tuberculous tubular stenosis of the rectum are well-known conditions. The spread of inflammation from the female pelvic organs may give rise to true stenosis of the sigmoid or pelvic colon.

Detailed accounts of my two cases may now be given. They are of especial interest for the two following reasons: 1. Both of them were mistaken by me and others before exploration for growth of the descending or sigmoid colon. It is possible that the mistake would not have been made if sigmoiditis had been borne in mind. In any case I do not think that a correct diagnosis would have materially altered the treatment, but the prognosis given before the operation would have been different. 2. Circumstances made it necessary for different operations to be performed for the two patients. In one the ileum was short-circuited to the front wall of the pelvic colon 5 inches from the anus. This saved the patient's life and made her much more comfortable. It improved her general condition, but it has not cured her. In the other the diseased part was resected with complete success.

CASE 1.—The first case was that of a lady, aged 60 years, a patient of Dr. J. Kidd. She had suffered from constipation for many years. There were only two actions of the bowels in a fortnight during May, 1908, while the patient was on a holiday at Lugano. The symptoms had got very much worse by July 21st, 1908, when she was seized with severe colicky pains in the abdomen. The bowels were opened with difficulty, so that opening medicines had to be taken regularly, and these were followed by liquid motions. During the last few weeks liquid stools and slime were frequent, but no formed motions were ever passed. Tenesmus had been very severe and spurious diarrhœa urgent and often uncontrollable, so that a diaper had to be worn. Usually only mucus and flatus escaped, but this gave great relief. Flatulence had been very troublesome. The wasting had been considerable. On examination the patient was found to be thin, shrivelled and anæmic. The bowels had not been opened for three days. The tongue was furred and white, and the abdomen was distended but quite soft and supple. Obvious peristalsis could be seen, and this was especially marked in the transverse colon. The descending and sigmoid colon could be felt in the iliac fossa, and the swelling and hardness extended up into the left loin and under the cover of the ribs near the splenic flexure, where the patient said that she had had much pain and had noticed gurgling. There was shifting dulness in the flanks. The transverse colon was greatly dilated. There was no tumour felt on pelvic examination. A systolic apical bruit was heard and the ankles were œdematous. Chronic intestinal obstruction due to growth of the descending colon was diagnosed, and an operation advised for its relief. The patient expressed strong disapproval of colostomy, but this did not seem likely to be necessary, because either resection or lateral anastomosis was thought to be possible. Upon opening the abdomen on August 22nd about two pints of sanious fluid escaped. The colon from just below the sacro-iliac synchondrosis to the splenic flexure was greatly thickened, red, and œdematous. It formed a rigid tube with a very thick wall and very narrow lumen. The mesentery had shortened so much that only a very short meso-sigmoid could be found, and there was no sigmoid loop of bowel, but only a nearly straight rigid tube, ending abruptly at the splenic flexure. There was no meso-colon. The peritoneal tissues on either side and behind the colon were œdematous. In view of the patient's feeble condition and the presence of subacute obstruction which was nearly complete, and the condition of the distended transverse colon which was full of hard scybala, immediate resection was considered inadvisable and too risky. Moreover, the extent of bowel to be removed was very considerable, and the patient had refused her permission to a colostomy. It was therefore decided to join the ileum to the front of the pelvic colon or rectum at the lower border of the disease. Even there the bowel was not quite healthy, and it was so fixed that the anastomosis was very difficult. The friable condition of the large intestine and the need to make the opening very low down added to the difficulties. However, with the aid of clamps and the Trendelenburg

[1] THE LANCET, March 21st (p. 843) and 28th (p. 928), 1908.

position, a side-to-side union was made between the ileum and the pelvic colon, the lower angle being about 5 inches from the anus. Three layers of sutures were used, one piercing all the coats, and two sero-muscular; and the great omentum was wrapped round the front and upper side of the anastomosis. The anæsthetic was ably given by Dr. F. E. Shipway, and Mr. Norman Flower, my house surgeon, assisted at the operation. The pain and rectal tenesmus were greatly relieved by the operation, and death from intestinal obstruction was averted. At first the bowels were opened very freely, generally about six or eight times in 24 hours. The motions were usually liquid, very offensive, and often contained a little blood. Occasionally some scybala came away with the daily enema which was given. Sour milk was tried and a variety of other things without affording much relief. The abdomen remained rather distended, supple, and flatulent. The motions gradually became less frequent and more solid. The thickened descending colon could be felt quite easily. The patient was able to leave the nursing home and return to her home considerably better ten weeks after the operation. Two months later Dr. R. J. Ryle kindly wrote:—

On the whole her condition is not much changed. The abdomen is constantly wind-distended and keeps the outline of a football. On the whole, we think the distension is a little less, but the abdomen remains always tympanitic except over the left flank, where there has always been a less resonant region. At times large moving coils can be seen. The bowels have in general been relaxed, two or three loose actions per day being the rule, but just lately within the last three weeks they have taken a turn of constipation, relieved only by enemata. She cannot turn over in bed without a feeling of dragging. She walks with the aid of a nurse on one hand and a stick in the other once or twice a day. The rest of her time is spent on a sofa in the room next her bedroom. Food is really no difficulty. She seems able to take one food as easily as another, and I cannot find that the intestinal distension is at all affected by the character of her food. I tried lacto-bacillin (Metchnikoff's form), but with no result. She is perhaps a little stouter in the limbs and looks well in the face. There is, at any rate, no evidence of any growth, which is a satisfactory feature, and we try to find some symptom of slow improvement.

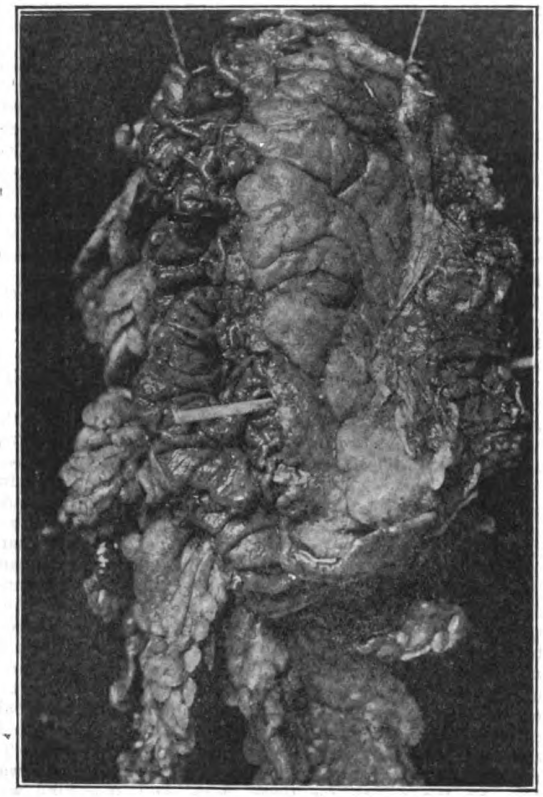
About this time I suggested a second operation, either the resection of the diseased part of the colon, or section of the lower end of the ileum with blinding of both cut ends; but the patient did not wish anything more done. At the middle of November, 1909, Dr. Ryle kindly wrote as follows:—

As to Mrs. ——, there is not very much change in her general condition. She spends most of her life on a sofa in her bedroom, but goes out in a bath chair two or three times a week. Her abdomen has still the figure and resonance of a football, and she complains a good deal of feelings of a great weight "inside" and of "dragging" if she turns over in bed or moves much. She has become a good deal stouter. She takes nourishment very well and suffers less from thirst. She complains still of tenderness or pressure in the left hypochondriac region, where there is still a little definite fulness. The enlarged glands, which were easily felt along Poupart's ligament on the left side when she came home a year ago, have quite gone. There are at times various joint pains, especially in the knees; but her general health is good. There is sometimes complaint of discomfort and tenderness in the bladder. With a little cascara and strychnine twice a day after meals, aided by an occasional cascara pill at night, or rarely a grain of calomel, things are kept going. The actions are, more often than not, not properly formed. An enema about once a week or so is given to make sure that the lower part of the alimentary canal is cleansed. She complains of having very little expulsive power in the rectum.

CASE 2.—A stout man, aged 49 years, was referred to me by Dr. W. Hale White and Dr. C. J. Woollett in the middle of September, 1909. Dr. Woollett gave the following excellent history:—

I have known Dr. —— for about five years, during which time I have occasionally attended him for laryngitis (simple) and for shingles; his general health was good, and he weighed about 16 stones. This spring Dr. —— consulted me about a pain from which he sometimes suffered on the left side of the abdomen. The pain was not constant and, as a rule, not severe. He stated that he had had it, on and off, for the last 30 years, and that, when he was a student, a German doctor told him that he was suffering from enlargement of his colon. Dr. —— told me that he suffered habitually from constipation, to overcome which he was in the habit of taking purgative pills, and consequently had two or three actions of the bowels per diem; he did not pass blood. As a rule he had a good appetite, was a quick eater, and of a very energetic temperament. On inspection and palpation of the abdomen, and on rectal examination, I could detect nothing in the shape of a tumour. Deep pressure over the sigmoid caused some pain. The abdominal walls were then rather fat. At the beginning of September I was again called to see my patient. He had lost about 2 stones since my last attendance and had suffered frequently from his abdominal pain. At this date he complained of the pain being more acute, and he had had rigors on the previous day. I do not think that he had vomited. On examination there was a temperature of about 102°, a quick pulse, furred tongue, and excessive tenderness on pressure over the sigmoid. The treatment consisted of hot fomentations and a febrifuge medicine and enemata. After a few days the temperature became normal, and the tenderness subsided, and then for the first time I discovered a tumour in the sigmoid region. I advised my patient to see Dr. Hale White who sent him to you.

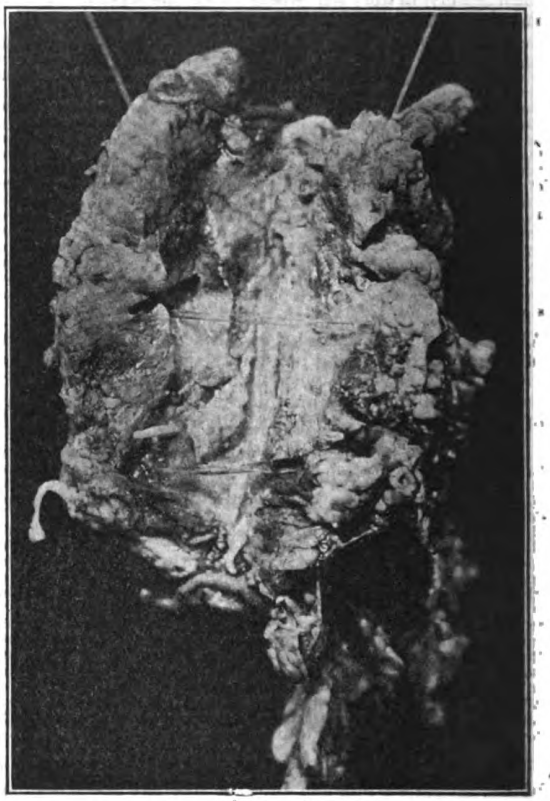
Upon examination Dr. —— looked sallow, wasted, and flabby, but not thin. The abdomen was very flabby and had clearly wasted a good deal. In the left iliac fossa a rounded moveable swelling of about the size of a cricket-ball could be felt. It moved more freely from side to side than vertically. He suffered much from flatulence, indigestion, and insomnia. His worse symptom was very severe tenesmus, which made him pay frequent visits to the lavatory, where he sometimes stayed for an hour at a time without getting much relief, only passing mucus and flatus. The pain extended up along the colon as far as the ribs on the left side. Upon rectal and bimanual examination no tumour could be discovered in the pelvis or bowel. The diagnosis was somewhat uncertain, especially on account of the unusually long duration of the symptoms of obstruction and the history of rigors, but an exploration seemed to be imperative. A growth of the sigmoid colon with inflammatory changes around it was considered to be the most probable diagnosis, but in view of the long history Dr. Hale White suggested that the disease might be non-malignant. The bowels having been cleared out as well as possible by means of castor-oil, ether was administered by the open method by Dr. W. H. Trethowan. The abdomen was opened through the lower part of the left rectus, and a tumour, thought to be malignant, was discovered near the middle of the sigmoid colon and its mesentery. The lumen of the bowel was considerably narrowed, but the bulk of the swelling was towards the mesentery, which was much shortened and very thick. Nodules, thought to be enlarged glands, also extended upwards along the inferior mesenteric vessels for several inches. Resection was decided upon, although the condition did not appear to be a very hopeful one because of the extensive infection of the lymphatic glands. The Trendelenburg position was adopted, and the small intestines were displaced upwards and to the right and carefully packed off with gauze pads. An incision was made along the parietal peritoneum to the left of the root of the mesocolon, and extending upwards nearly as far as the splenic flexure. By gauze dissection the sigmoid and its mesentery were separated from the iliac fossa and turned inwards. The ureter, which was attached to the mass, was carefully separated off and displaced backwards and inwards out of the way. When the bowel had been sufficiently freed it was turned back to the left, and the peritoneum covering the inferior mesenteric vessels was carefully incised close to the spine. The lymphatic vessels and glands were separated from the blood-vessels by gauze dissection from above downwards. The splenic flexure was mobilised after the manner recommended by Moynihan. The bowel and the mesentery were then clamped and the diseased parts were isolated and removed, care being taken to preserve the continuity of the superior hæmorrhoidal vessels. The mesentery was tied and the rent in it was sewn up. An end-to-end union was made by direct sutures, the first layer passing through all the coats, the second including only the sero-muscular tissue. A small temporary drain was placed at the lower angle of the wound, which was elsewhere closed in layers in the usual way. To ensure absolute rest to the bowel very little but water was given by the mouth for three days, and morphine was injected subcutaneously to procure sleep on the first and second nights. No purgative was given by the mouth and the bowels were allowed to open naturally with the aid of a small oil enema on the eighth day. The patient made a good recovery and left the private home a month after the operation. Soon afterwards he went away for a month's holiday. Dr. Woollett has kindly kept me informed of his further progress which has been uninterrupted. I saw the patient on Feb. 24th. He was looking very well and had gained over 2 stones in weight. He had been doing his usual hard work for a month without any inconvenience beyond a little "indigestion." He occasionally has to take an aloin pill. Six and a half inches of bowel were removed. Upon slitting it open along its free border no growth was seen. Something bulged in at the mesenteric border. The mucous membrane was neither thickened nor ulcerated. Upon cleaving the mesentery many necrotic foci were seen (Fig. 2), and several of these had broken down into small abscesses. A probe could be passed into several pouches (Fig. 1), extending into the mesentery from the mesenteric border of the bowel, and reaching quite near to some of the breaking-down areas. The necks of the pouches were quite narrow, so that



they would be overlooked unless specially sought. None of the diverticula were visible on account of the thickness of the fat mesocolon. A piece of the diseased mesentery was sent to the Clinical Research Association for microscopic examination. The following report was returned:—

This specimen is composed of fat and fibrous tissue with occasional nerve fibres. It is inflamed and shows marked leucocytic infiltration and endothelial proliferation, with a phagocytic giant cell here and there. We find no evidence of tubercle or of malignant growth.

Diagnosis.



Monsarrat,[2] and especially Moynihan[3] and Maxwell Telling[4] have drawn attention to the mimicry of malignant disease by inflammatory stenosis of the sigmoid colon. It is very important to bear this in mind. The following points may suggest the innocent nature of the obstruction. 1. The long duration of symptoms, especially the history of life-long constipation. Both my patients had suffered severely from constipation for many years. 2. The absence of blood in the stools on repeated examination. In one of my cases blood was never noticed, but no microscopic examination was made. In the other blood was infrequent, but was occasionally present towards the end. In this case the mucous membrane was seen to be considerably inflamed at the operation. But in most cases the inflammation seems to to be almost confined to the outer coats of the bowel, with the result that bleeding is unusual. The repeated presence of pus in the motions is important, especially in the absence of blood. In my two cases the pain and tenesmus were very severe and I think more marked than in any case of malignant disease that I have ever seen. The slight degree of cachexia is said to be of value, but in both my cases the disease had lasted a long time when I first saw them and the obstruction was almost complete in one of them. In the other there was suppuration between the layers of the mesentery. It is not surprising therefore that each had lost several stones in weight and looked very ill. The sigmoidoscope may be of value in some cases, perhaps excluding growth, but it was not used in either of my patients for various reasons. One of them was too ill to waste time on the examination, immediate relief of the obstruction being necessary to save life. The presence of an obvious tumour and the severity of the symptoms demanded an early exploration in my second case. An anæsthetic would have been necessary for the examination in both cases in view of the extreme local tenderness. Moreover, it is hard to believe that the sigmoidoscope would have helped very much in these particular cases. In one of them the inflammation was taken for growth even after the abdomen had been opened. But when chronic inflammation has led to stenosis of the bowel giving rise to chronic intestinal obstruction, palliative treatment is not likely to afford permanent relief. Laxative medicines and repeated enemata may make life tolerable for a time, but an operation becomes necessary eventually in order to save life, and it is wise to recommend this before the obstruction becomes complete so that a radical operation may be hopefully undertaken at one sitting.

FIG. 1.

Sigmoiditis and meso-sigmoiditis. View of the piece of sigmoid colon removed from the left and behind, showing glass rods introduced into two of the diverticula, which extend into the mesentery and have given rise to chronic inflammation and suppuration between the layers of the mesentery. Note the enormous increase of fat in the mesentery, especially of its anterior surface. The mucous membrane is healthy, but the lumen of the bowel was greatly narrowed by the encroachment of the inflammation of the mesentery and the outer coats of the bowel.

FIG. 2.

Sigmoiditis and meso-sigmoiditis. The same specimen as in Fig. 1. The mesentery has been cleft longitudinally. The two halves are held apart by means of glass rods, thus showing the extreme amount of fibrosis of the mesentery, with many necrotic foci and the ends of two probes which were introduced into diverticula.

The Choice of Operation.

So few cases have been recorded that it is difficult to say what is the best thing to do when a correct diagnosis has

[2] Brit. Med. Jour., vol. ii., 1907, p. 65.
[3] Brit. Med. Jour., vol. ii., 1907, p. 1381, and Edinburgh Medical Journal, March, 1907.
[4] THE LANCET, March 21st and 28th, 1908.

been made either before or at the operation. Dr. Telling has drawn attention to the fact that these patients are particularly susceptible to infection. It is very important to bear this in mind when deciding upon the safest and most suitable operation for any given case. Peritonitis and suppuration of the abdominal wall have followed in a large proportion of cases. It is very important to take every precaution against infection. The following operations may be briefly discussed: (*a*) colostomy; (*b*) ileo-sigmoidostomy; and (*c*) resection.

(*a*) *Colostomy.*—This operation affords much relief without great risk to life, but an artificial anus has so many obvious disadvantages as to make it undesirable for sensitive patients. As a temporary measure it may be tolerated when primary resection or short-circuiting is not safe or is impracticable at the time. It is particularly objectionable for the permanent treatment of patients who are not suffering from malignant disease and may be expected to survive for many years. It is of the utmost importance to bear in mind that what appears to be an obvious malignant growth of the sigmoid colon may be only inflammatory. The mistake may be made even when the abdomen is opened. When operating for acute following upon chronic intestinal obstruction, or when performing colostomy because a supposed growth is too adherent and extensive for removal, it may be useful to remove a small piece for microscopic examination. It must be remembered, however, that a good deal of inflamed tissue surrounds a growth, so that too much reliance must not be placed upon a negative report. Occasionally the rest and drainage afforded by the colostomy may lead to partial or even to complete disappearance of the stricture so that the artificial opening may be closed. In other cases a temporary colostomy may be followed by secondary resection of the diseased part of the colon and the restoration of the continuity of the bowel.

(*b*) *Ileo-sigmoidostomy.*—It is unfortunate that the disease is usually in the part of the colon which is the most convenient for the anastomosis. Moreover, the anatomical relations are greatly altered by the disease. The meso-sigmoid is shortened and thickened and the disease may extend to the descending loop of the sigmoid or pelvic colon, so that it is almost impossible to make the anastomosis in healthy bowel below the disease. When the stenosis is high up, as, for instance, in the splenic flexure in Mr. Moynihan's [5] case, ileo-sigmoidostomy is easily performed and safer than resection; and the result was good in Mr. Moynihan's case. In my first patient the disease extended from the splenic flexure to the upper part of the pelvic colon. The patient was too ill for an extensive resection, and she strongly objected to colostomy. The ileum was therefore joined to the front wall of the pelvic colon which was not free of inflammation. The result in this case would probably have been better if I had either narrowed or occluded the ileum between the anastomosis and the cæcum. Mr. Moynihan narrowed the ileum in his case. When the anastomosis has to be made so very low down in the large intestine it is apt to be followed by more or less diarrhœa lasting for a long time. Ileo-sigmoidostomy is not likely to be practicable in many cases of sigmoiditis, especially when the disease extends to the meso-sigmoid. Short-circuiting is not likely to completely cure the disease permanently, for the diverticula and inflamed tissues are left in the body and they give rise to further trouble, just as the diseased appendix does until it is removed after appendicitis. When it is practicable it may save life and afford relief. It remains for experience to prove how far the relief may be permanent. If secondary symptoms develop there is no reason why secondary resection should not follow the anastomosis when the general condition of the patient is more satisfactory.

(*c*) *Resection.*—Very few cases of resection for simple stenosis of the colon are recorded. When the local condition is well advanced and the obstruction is chronic and incomplete, resection is probably the best treatment and affords the best guarantee of complete recovery. The greater risk attending it is worth running in order to avoid an objectionable colostomy. In the absence of complete obstruction primary resection is far preferable to colostomy followed by secondary resection. In some cases secondary resection may become necessary after a primary short-circuiting operation.

Queen Anne-street, W.

VICIOUS CIRCLES ASSOCIATED WITH DISORDERS OF THE NERVOUS SYSTEM.

BY JAMIESON B. HURRY, M.A., M.D. CANTAB.,
PRESIDENT, READING PATHOLOGICAL SOCIETY.

THE central nervous system is the capital of the human microcosm with whose remotest outposts it is, for good as well as for ill, in constant communication. In health the closest correlations and polarities exist between it and every other organ; in disease such correlations and polarities are no less intimate. Generally speaking, such correlations make for good, one organ assisting the other in beneficial reciprocity. But there are occasions when disorder in the one breeds disorder in the other, cause and effect acting and reacting injuriously on each other. When such is the case, there is established a *circulus vitiosus*, a grave condition which has hitherto received but scanty attention.

It would be impossible to enumerate the reciprocal interdependencies operating in the healthy organism: fresh illustrations are constantly being discovered with the progress of research. Equally impossible to enumerate the reciprocal interdependencies which accompany pathological processes. But it will be of interest to point out some examples as met with in one great group of disorders—viz., those of the nervous system. For the sake of clearness functional and organic disorders will be treated separately.

I. *Functional Disorders of the Nervous System.*

(*a*) *Neurasthenia.*—Perhaps the commonest and most protean of such functional disorders is neurasthenia. Owing to its ubiquity the disease has been described as *non morbus, sed morborum cohors.* There is scarcely an organ that may not at times be affected. Vicious circles may complicate any of the manifestations of neurasthenia, whether the mental or psychic faculties, or the digestive, vascular, sexual, or other systems are involved. "In no complaint does it happen more frequently that the patient gets into a vicious circle, the fundamental disorder producing symptoms which again maintain and aggravate the disease." [1] A familiar example is insomnia, a most obstinate disorder in the neurotic, and one which so depresses the nerve centres as to aggravate the primary trouble. Indeed, Clifford Allbutt describes insomnia as "almost a universal feature of neurasthenia; as one of the links of the vicious circle in which the victim is enchained." [2] Mental depression and malnutrition often accompany the insomnia, each factor reacting on the other.

Diese Depression bleibt nicht ohne Rückwirkung auf die Ernährung, den Schlaf und die Vitalen Functionen, und so geht es in einem unseligen Circulus vitiosus immer weiter abwärts und schwere andere, nicht mehr in der Rahmen der Neurasthenie gehörige Neurosen und Psychosen, können sich in kürzerer oder längerer Zeit entwickeln.[3]

Shakespeare well describes the condition:—

> "Sorrow's weight doth heavier grow
> Though debt that bankrupt sleep doth sorrow owe."

Even apart from insomnia melancholy often causes malnutrition, which in turn reacts on the mind. In Rayner's words:—

In diseased conditions, especially in the depressed emotional states, this interaction of the mind on the body and of the bodily state on the brain establishes a vicious cycle of nutritional disorder, which tends to increase and prolong the disease.[4]

Krafft-Ebing has drawn attention to a similar mental condition set up in neurotic persons when attacked or even threatened by illness:—

Mit der Zeit entwickelt sich hier ein wahrer *Circulus vitiosus* gestörter Beziehungen zwischen Psyche und Leiblichkeit, in dem eine Fülle von psychisch ausgelösten Functionsstörungen in den extracephalen Organen projicirt wird und diese wieder auf die Psyche, ganz besonders auf die Stimmung zurückwirken.[5]

That the power of the mind over disease was well known to the Greeks is shown by a quotation from Euripides [6]:—

> Λῦπαι γὰρ ἀνθρώποισι τίκτουσιν νόσους.

Vicious circles may be established by the use of alcohol and various drugs.

In a neurasthenic individual a stimulant gives temporary relief, but leaves the neurasthenia as it is or even increases it, and afterwards the neurasthenia causes an irresistible desire for the stimulant which, while it gave relief, aggravated the disorder. Therefore the substances in question cannot be considered as the only causes of the disorders mentioned, but they form a secondary link in the vicious circle, which always in pathology plays such an important rôle, the primary link being the morbid constitution.[7]

The morphia habit gives rise to a similar concatenation of symptoms.

Dans ces conditions (i.e., in morphinomania) le sujet tourne dans un véritable cercle vicieux. ..... Avant le repas il se pique pour exciter l'appétit toujours défectueux; après le repas, nouvelle piqure pour faciliter la digestion. ..... Aussi les doses injectées ne tardent-elles pas à devenir de plus en plus répétées, de plus en plus considérables.[8]

We may now pass to forms of neurasthenia in which some peripheral organs are reciprocally involved with the central nervous system. The sufferer, by fixing his consciousness with morbid intentness on his organs, creates not merely unhealthy sensations but also functional disorders—e.g., palpitation, flatulence, polyuria, nausea. It is indeed difficult to assign the limits to auto-suggestion, so far-reaching and imposing may be the consequent disturbance. An illustration is met with in women in whom ovarian or uterine coexists with nervous disorder. In such cases we have frequently "to deal with a vicious circle, with local and constitutional states so interacting that no real improvement is possible until both the general and local states receive their due share of attention."[9] Herman gives an example:—

In chronic ovarian pain with neurasthenia effects follow one another in a vicious circle. The patient feels more severely the ovarian pain because her nervous system is too sensitive. The persistent ovarian pain keeps the nervous system weak and sensitive and further weakens it. In bad cases the circle can only be broken by removing the ovaries.[10]

A vicious circle is frequently associated with sexual malpractices and with spermatorrhœa.

Ausserordentlich häufig besteht bei Neurasthenikern beiden Geschlechtes, hauptsächlich bei Ledigen, die Neigung den Geschlechtstrieb auf *masturbatorischem Wege* zu befriedigen; es ist oft schwer zu unterscheiden, ob die Masturbation als die Folge oder als die Ursache der sexuellen Neurasthenie anzusehen ist, gewöhnlich handelt es sich um einen Circulus vitiosus; infolge früherer Masturbation stellen sich sexuelle Störungen ein, welche den normalen sexuellen Verkehr unmöglich machen, und da die normale Befriedigung dadurch aufgehoben ist, wird die Masturbation fortgesetzt, wodurch wieder eine Besserung der sexuellen Beschwerden verhindert wird.[11]

Anæmia with its secondary effects on nutrition may form a grave complication of neurasthenia. Löwenfeld thus describes it:—

Vielfach ist die bei Nervenleidenden bestehende Anämie nicht Ursache, sondern nur Folge der nervösen Affektion. Letztere führt durch Beeinträchtigung des Appetits und der Verdauung (nervöse Dyspepsie) zu Störungen der Allgemeinernährung und damit zu einem Circulus vitiosus, indem die Verschlechterung der Allgemeinernährung sehr wesentlich zur Unterhaltung und Steigerung der bestehenden nervösen Erschöpfung und damit auch der nervösen Dyspepsie beiträgt. Diesen Circulus vitiosus zu durchschneiden, erweist sich oft als eine der schwierigsten therapeutischen Aufgaben, welche an den Arzt herantreten können.[12]

The vascular, digestive, and sexual circles associated with neurasthenia apply *mutatis mutandis* to the allied disorder hysteria.

(*b*) *Other functional disorders.*—Apart from neurasthenia various conditions are met with in which cause and effect bear reciprocal relations to each other. Overwork supplies a common example. The overwork produces headache and insomnia, which react on each other and perpetuate the condition unless the circle can be broken. Again, sickness in a nursling may so upset the equanimity of the nursing mother as to injure her supply of milk. This in turn causes illness in the infant and so further injures the health of the mother.

Between the nervous system and the gastro-intestinal tract many illustrations of disordered correlations may be observed. A series of these have already been published,[13] but various others also occur. Ewald draws attention to a state of anorexia induced by cerebral disease and reacting on the mental processes. "Thus a vicious circle is established which may under certain conditions lead to the most serious consequences."[14] Axenfeld, speaking of neurotic dyspepsia in women, says:—

Si l'état dyspeptique s'accentue davantage encore, la malade tourne dans un véritable cercle vicieux morbide; le nervosisme ayant créé la dyspepsie, celle-ci produit l'anémie qui, à son tour, entretient dans le système nerveux cet état si pénible de faiblesse irritable dont souffrent les malades.[15]

The inertia of the nervous system produced by dyspepsia reacts on all the eliminating organs, causing arrears of excretion to accumulate, which again increase the inertia.[16] Especially is this the case where chlorosis is superadded. Even the lungs come in time to be involved, and "the patient lies in a vicious circle of a reduced activity of the respiratory centre, due to the anæmia it should help to dispel."[17]

I have elsewhere described numerous reciprocal interdependencies between the nervous and the vascular systems.[18] Only two illustrations need here be given.[19] In heart disease vomiting is not uncommonly due to purely nervous influences acting through the pneumogastric. "The vomiting forms a link in the vicious circle which may ultimately prove fatal; and if it refuse to yield it accelerates the end." Again, "Depressing emotions contribute to failure of compensatory hypertrophy of the heart; and in this respect also a vicious circle is formed, which often can be broken by judicious management." Epilepsy is associated with another variety of circle, inasmuch as every attack increases the labile condition of the nerve centres and facilitates recurrence. In fact, recurrence is to a large extent the result of the previous attack, culminating at times in the status epilepticus.

The accompanying figure shows how these circles can be represented diagrammatically.

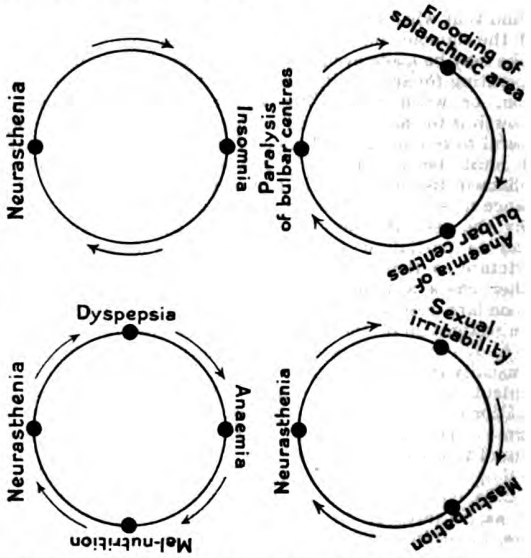

Diagram showing the analysis of vicious circles into component factors.

II. *Organic Diseases of the Nervous System.*

Leonard Hill draws attention to a vicious circle which is established when intracranial hæmorrhage causes increased cerebral compression and thus leads to a secondary increase of compression by the obliteration of the veins and capillaries in the affected area and a consequent congestive œdema. He says:—

The high blood pressure which exists in those capillary areas surrounding the seat of complete vascular obliteration will lead to increased transudation of fluid, since plasma may pass more easily into the brain substance than the blood through the compressed capillaries. The transudation will take place at almost arterial tension, will increase the volume of the foreign body, and so will lead to compression of other capillary areas. A *circulus vitiosus* is thus established and the cerebral anæmia may spread indefinitely.[20]

And again:—

In meningitis, tubercular meningitis and cerebral abscess, compression can arise by the accumulation of inflammatory exudations, by inflammatory dilatation, by thrombosis and blocking of vascular areas; and whenever the Sylvian aqueduct and the veins of Galen are obliterated by intraventricular transudation. In all these pathological states a *circulus vitiosus* can be established leading to advancing cerebral anæmia. The pathological cause of ventricular hydrocephalus is no doubt to be found in blocking of the veins of Galen and the Sylvian aqueduct.[21]

Another form of circle may be established in cases of hydrocephalus where the ventricles are dilated with fluid. The dilated ventricles may so displace the adjacent parts as to press on and increase the obstruction to which the accumulation of fluid was primarily due. For example, the cerebellum and medulla may be pressed down into the foramen magnum so as to plug that aperture. Such plugging in turn increases the distension of the ventricles and renders the condition a self-perpetuating one. The dilated ventricles again (by compressing the membranes of the nerve roots) may close the lymph paths or natural drainage

channels, which closure in its turn aggravates the ventricular dilatation.[22]

Inflammatory conditions, where toxins dilate the blood-vessels, alter the metabolism of the tissues and raise the osmotic pressure (by increasing the crystalloidal cell-products), are often complicated by a vicious circle. The tissues swell at the expense of the blood-supply of neighbouring parts, where there are no toxins and no vaso-dilatation, or œdema. "The anæmia so produced may in its turn damage the tissue metabolism of these parts, and set up congestion and œdema therein, and thus a vicious circle may be established."[23]

Circles Associated with Injudicious Treatment.

It cannot be doubted that vicious circles have been established by erroneous treatment in various disorders of the nervous system, although it may be hoped that such error is less common than formerly. The abuse of bromide of potassium in traumatic neurasthenia supplies a case in point. The outstanding symptoms of many of the spinal injuries that follow upon railway accidents are spinal tenderness, stiffness, and pain, associated (in severe cases) with neurasthenia and other signs of nervous prostration. These symptoms were supposed to indicate that irritation or inflammation of the spinal cord was present, which must be arrested by, or controlled by means of, a sedative. Consequently it became the fashion to administer bromide of potassium in large doses for weeks together. Now bromide may produce symptoms closely akin to those of traumatic neurasthenia, with the result that unwary practitioners confused the symptoms due to the bromide with those of the traumatic neurasthenia and continued to increase the dose in the hope of checking those symptoms. The effect was that not infrequently patients got worse and worse under the influence of the drug. As soon as the drug was discontinued, all the symptoms of the supposed neurasthenia vanished.

A case of litigation is actually on record in which a claim was based on the supposed presence of an inflammatory affection of the spinal cord and its membranes as proved by a cutaneous eruption, whereas this cutaneous eruption was in point of fact an acne induced by bromide of potassium![24] This example shows how cause and effect may be inextricably confused, increased doses of bromide of potassium being administered to remove the very symptoms the drug had produced!

Another artificial circle may be established where minor uterine or ovarian disorders receive undue medical attention and thus provoke in the patient an unhealthy mental condition which exaggerates and perpetuates the trivial local disorder. Well-intentioned but injudicious professional solicitude thus forges a chain within whose links the neurotic woman may be bound until her life becomes a wreck. Wholesome advice combined with tonic treatment would generally prevent so dire a disaster.

As a third and last example may be mentioned the abuse of strychnine in such cases of severe shock as accompany major operations. Under such conditions there is exhaustion of the nerve centres combined with dilatation of the splanchnic area and a marked fall of blood pressure. The routine treatment formerly consisted in the use of such stimulants as strychnine or brandy. Recent research, however, based on manometric observations, has proved that stimulants are useless in arresting the fall of blood pressure. Indeed, their administration has the effect of still further exhausting the nerve centres and of aggravating the condition. In other words, the symptoms of shock led to the administration of strychnine, which administration in turn increased the shock.[25] Many cases might have recovered but for the strychnine.

Conclusion.

Space will not allow of a discussion of the treatment of vicious circles, whose number and area are practically unlimited. But emphasis may be laid on the importance of an accurate diagnosis of the interacting processes. The old maxim applies—*Qui bene diagnoscit, bene medibitur*—and the alert physician, remembering that the condition is one which *vires acquirit eundo*, will do well to act on another maxim—*venienti occurrite morbo*. But at times the diagnosis may be far from easy, since one or other factor may be so concealed that the closest investigation is required. Well worth pondering are the words of Clifford Allbutt:—

> I would impress upon the reader the importance of searching for any vicious circle of function, and if any can be found of cutting any link in it whatsoever. The stretching of the sphincter ani in one lady patient of mine restored her to herself after months of nervous restlessness most wearisome both to herself and her friends. In neurotic persons a floating kidney, a disorder of the uterus, a chronic rhinitis, or some other local irregularity, trivial enough perhaps in itself, may close and perpetuate the vicious circle of disorder. The treatment of every case must, therefore, begin with a minute search for any such local factor, and the cure of it must be the first step in the treatment.[26]

To the painstaking physician will fall the honour of unravelling many a Gordian knot in obscure disease and of enabling his patient—

> "Revocare gradum superasque evadere ad auras."

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES ON A CASE OF FAILURE OF THE HEART'S ACTION UNDER CHLOROFORM; RE INDUCTION OF RHYTHM BY MASSAGE THROUGH THE DIAPHRAGM.

BY T. C. RUTHERFOORD, M.D., B.S. DURH., M.R.C.S. ENG., L.R.C.P. LOND.,

CAPTAIN, I.M.S.; CIVIL SURGEON, BILASPUR, CENTRAL PROVINCES.

THE patient, an otherwise healthy and well-developed native Christian of the labouring class, aged between 30 and 35 years, was admitted to hospital on Jan. 2nd, 1910, for the treatment of hæmorrhoids.

On Jan. 5th, after the usual preparation, the patient was anæsthetised, the sphincters dilated, and the rectum washed out. A Whitehead's operation was then performed in the usual way. The greater part of the operation had been completed—the right half of the mucous membrane having been stitched in position—when the respiration stopped and the patient became cyanosed; he had been breathing badly for a short time before respiration ceased. I thereupon performed artificial respiration for about half a minute by Silvester's method. The pulse was sought for, but none could be detected at either wrist. The heart was, therefore, auscultated with a binaural stethoscope, but no sounds could be heard.

Rapidly washing my hands, I made a longitudinal incision in the mid-line of the belly 4 inches long, the upper end of which was 1 inch below the ensiform cartilage. It was noted that no hæmorrhage occurred from this wound until the recurrence of cardiac contractions. The right hand was inserted palm upwards between the liver and the diaphragm to the left of the falciform ligament of the liver, the left hand being placed over the præcordial region. A watch was held before me, and I then made powerful compression of the heart between the hands at the rate of 60 to the minute. It was noted that not only could no cardiac contraction be felt but that the outlines of the heart itself could not be distinguished with any certainty. After the heart had been

squeezed about one dozen times the whole organ was felt to suddenly harden, following which a strong wave of contraction from above downwards occurred. Massage was immediately discontinued. After about one second another and more powerful contraction occurred, followed by contractions of about equal intensity at regular intervals of probably about one second. The pulse was then felt by Dr. Ramanna and found to be 60 per minute and of quite good pressure and expansion, all things considered.

I then re-washed my hands and rapidly stitched up the abdominal wound with through-and-through linen thread sutures and applied a collodium dressing and bandage. Dr. Ramanna and Dr. Gupta, assistant surgeons, were present throughout the operation. The administration of chloroform was discontinued from the time the respiration ceased, although after suturing the abdominal wound the Whitehead's operation was rapidly finished off. The patient appeared to be quite unconscious until after the dressings had been applied to the anus when he began to groan. An injection of 10 minims of liquor strychninæ was given hypodermically before he was removed to the ward, which operation was conducted with extreme care at about 3 P.M.—i.e., about two hours after the commencement of the anæsthetic. He was placed in a bed, the foot of which was raised about 1 foot and covered with two blankets. Fairly free, though not excessive, hæmorrhage had occurred during the Whitehead's operation before the cessation of respiration, at which time the patient had been under the anæsthetic for rather less than one hour.

I visited the patient again at 5 P.M. and found the skin cold and the pulse 80, and of about the same volume and pressure as at the time of removal from the operating table. He was not completely unconscious as he tried to brush flies from his face and was very restless. I then gave him an intravenous injection of 10 minims of liquor strychninæ and 8 minims of liquor morphinæ, and had hot bottles applied outside the blankets. At 8 P.M. Dr. Ramanna reported that he had completely recovered consciousness. He was given another injection of strychnine and the hot bottles were renewed. I visited him again at 11 P.M. and found the skin warm and moist; the pulse was 80 and of good volume and pressure. He complained of thirst and abdominal pain, and was told to drink as much water as he wanted, but did not drink any. He was perfectly rational.

On Jan. 6th the patient vomited twice in the morning but took and digested some milk. Strychnine was again administered hypodermically. Dr. Ramanna noted a good deal of surgical emphysema of the abdominal and lower thoracic wall, due no doubt to one movement of artificial respiration, made by a well-intentioned assistant just after the belly was opened. I was unable to visit the patient on the 6th.

On Jan. 7th he still complained of pain in the abdominal wound, but the skin in the neighbourhood appeared healthy and there were no signs of peritonitis. The pulse was 72 and of good volume and pressure. He was ordered Mellin's food, rice, and milk.

On Jan. 8th—i.e., on the fourth day from operation—the patient could both sit and stand up and complained of insufficiency of food, for which reason an increase in the quantity of rice administered was ordered. Abdominal pain was much less and the general aspect of the patient was healthy. The anal wound appeared to be nearly healed. The stitches were removed from the anal wound on the tenth day and from the abdominal wound on the fifteenth, the latter having healed by first intention except in one place where the skin edges had not been accurately adjusted. Convalescence was practically afebrile throughout, and the patient was in perfect health when discharged from hospital about the twentieth day after operation.

Remarks.—The case is reported as complete recovery under these circumstances is still rare. The total period of the heart's inaction, though not accurately timed, cannot have been less than one minute nor more than two minutes. The entire absence of suppuration in the abdominal wound and peritoneum, bearing in mind that the skin was not washed and all the other circumstances of the case, is noteworthy.

Bilaspur.

NOTES ON A CASE OF INTESTINAL OBSTRUCTION DUE TO TWO DISTINCT CAUSES.

BY REGINALD M. MOORE, M.R.C.S. ENG., L.R.C.P. LOND.,
HOUSE SURGEON, WESTMINSTER HOSPITAL.

THE notes of the following case are of interest from the point of view of difficulty in diagnosis and of pathogeny.

The patient, a female, aged 56 years, was admitted to the Westminster Hospital from the Westminster Dispensary with a history of constipation and vomiting for three days. The vomit had become fæcal. On admission the temperature was normal. The abdomen was distended and tympanitic; the patient complained of tenderness on palpation. On examination of the rectum the fingers encountered, high up, a large hard nodulated lump. This mass was quite immoveable, covered by the rectal mucous membrane, and appeared to be outside the wall. The lumen of the gut was occluded. No hernial protrusion was to be found. Within half an hour after her admission an operation was performed by Mr. E. Rock Carling.

Operation.—With the intention of performing colostomy an incision was made in the left iliac region. On opening the peritoneum a quantity of clear fluid escaped, and several coils of greatly distended small intestine protruded in the wound. On passing the hand into the pelvis a mass of the size of a cocoanut was found almost completely filling the cavity. The lump was extracted with difficulty and found to be a subperitoneal fibroid which was attached to the uterus by a long pedicle; the pedicle was ligatured and the fibroid was removed. The uterus was beset with several small subperitoneal fibroids.

The large intestine from the sigmoid upwards was distended, but not to the same degree as the coils of small intestine that first presented in the wound. On tracing the gut from the cæcum upwards a Richter's hernia was found in the right internal inguinal ring. The portion of gut involved was situated at about the junction of the upper with the middle third of the small intestine. The piece of gut which was nipped was of the size of a shilling and was completely gangrenous, while for 5 inches on either side the intestine was paralysed and showed signs of commencing gangrene. In the neighbourhood of the hernia the peritoneal fluid was slightly turbid, and a small quantity of intestinal contents escaped at the seat of constriction. 14 inches of small intestine were resected, the cut ends were sutured, and a lateral anastomosis was made. A drainage tube was placed in the pelvis and the rest of the abdominal incision was closed.

Continuous saline infusion was given per rectum and strychnine and eserine were administered four-hourly. The patient did well until the third day after the operation, when peritonitis set in, and she died the same evening.

Necropsy.—Only a limited post-mortem examination was permitted. There was acute general peritonitis. The resection was situated six feet from the pylorus; there was no leakage at the site of the anastomosis, but the flow of water through the artificial opening was rather slow. The gut above and the stomach were very distended. Death was due to septicæmia.

Remarks.—The hernial sac was presumably of long standing; there is no evidence to show conclusively how long it had been occupied by the gut. Probably the course of events was as follows. Congestion or œdema of the fibroid in the pelvis compressed the rectum and pelvic colon until complete obstruction occurred; this led to distension, first of the large intestine and subsequently of the small intestine as far as the Richter's hernia; here the increase in size caused the invaginated gut to become strangulated and so caused a complete obstruction of the small intestine through paralysis of its wall and precipitated the vomiting which eventually became fæcal. Such a condition was practically impossible to diagnose before laparotomy, as there was no sign of a hernia externally; moreover, the pelvic condition afforded an explanation of the symptoms.

The only alternative to anastomosis was the insertion of Paul's tubes beyond the limits of the gangrenous area, but considering the site—namely, high up in the small intestine

—it was judged that immediate anastomosis gave the patient the better chance of recovery.

I wish to thank Mr. Rock Carling for permission to publish this case.

A CASE OF FATAL HÆMOPTYSIS IN CHILDHOOD.

BY RALPH BROWN, M.B., B.S. LOND., &C.,
LATE HOUSE PHYSICIAN, WESTMINSTER HOSPITAL.

THE patient, a girl, aged 3 years, was brought to hospital on account of having "a weak chest" and suffering from "worms," and was admitted. She had had no previous serious illnesses but had "always had a delicate chest." No family history of tuberculosis could be obtained. Worms had been noticed in the child's stools three weeks prior to admission, and there had been a falling off in her appetite during the same period. She had also suffered from a slight cough. On the day before she was taken to the hospital she had vomited.

On admission the patient was pallid and emaciated. Her temperature was 100° F. The movements of her chest were poor and the rate of breathing was unduly rapid, but the alæ nasi were not working. Her lips were slightly cyanosed. Percussion resonance was impaired on the left side. The breath sounds were harsh and, over the left lung, almost of a tubular character in places. Medium râles were audible all over the chest. The apex beat of the heart was in the sixth space 1 inch outside the nipple line. The heart sounds were feeble and irregular. The abdomen was distended and more resistant than normal.

The patient's general condition showed some slight improvement at the end of three days, during which time her temperature was of a very irregular type, varying between 99·2° and 101·8°. On the fourth day, while sitting up in bed, she had a sudden profuse hæmoptysis which proved immediately fatal.

Necropsy.—There was widespread tuberculosis affecting the glands of the abdomen and thorax, mostly of a chronic caseating type. The mesenteric glands were all large, some attaining to the size of a pigeon's egg and showing yellow caseation on section. The glands around the head of the pancreas and some in the mesocolon and the hilum of the spleen were in a similar condition, while all the mediastinal glands were affected, especially those at the tracheal bifurcation. Ulcers with tubercles were seen through the wall of the ileum, but there were none in the stomach or bladder. There was no peritonitis, though tubercles were scattered over the liver and spleen.

The pleura was a little adherent on the left side. There were universal pleuro-pericardial and pericardial adhesions, and on separating these numerous caseating tubercles were exposed. The left lung was the seat of diffuse tuberculous broncho-pneumonia, and in the lower lobe there was a cavity of about the size of a golf ball containing blood. The bronchi and trachea were filled with blood, and the hæmorrhage had extended to the stomach which was occupied by clot. In the right lung were small scattered tubercles. There was but little hypertrophy of the heart, and the endocardium was apparently normal. The larynx also was normal. On the right cerebral hemisphere internally were several patches of yellowish tubercle, and there was one in the white matter beneath the left island of Reil. The histological appearances were confirmatory of tuberculosis.

Remarks.—The most striking features of this case undoubtedly are that the immediate cause of death was a sudden profuse hæmoptysis and that this was the first and only attack thereof. Hæmoptysis, due to phthisis, is uncommon in children of such tender age and is very rarely fatal. Cavitation appears not to be very unusual in children, but difficult to recognise clinically. On this account perhaps it was formerly thought to be of less frequent occurrence than is actually the case. The presence of a cavity was not diagnosed in this instance. Cavities are usually small and of recent origin; this one was, comparatively speaking, of large size.

I am indebted to Dr. W. Murrell for permission to publish this case and to Dr. R. G. Hebb for access to pathological notes.

SECTION OF BALNEOLOGY AND CLIMATOLOGY.

Arthritis Deformans.—Climate of Egypt and North Africa and its Influence on Disease.

A MEETING of this section was held on April 20th.

The adjourned discussion on Arthritis Deformans, which was introduced at the preceding meeting on March 9th by Dr. R. LLEWELLYN JONES of Bath, was reopened by Dr. ARCHIBALD E. GARROD and Dr. P. W. LATHAM.

Dr. GARROD spoke in support of the view advocated by Dr. Jones in his opening paper,[1] that under the name of arthritis deformans we are in the habit of including several distinct morbid conditions, distinct alike in their pathological features, clinical course, and causation. He believed that the classification followed by Dr. Jones was as good a one as can be put forward at the present time. He devoted the greater part of his remarks to a discussion of the distinctive features of rheumatoid arthritis and osteo-arthritis respectively—features which are manifested on clinical examination, in radiograms, and at post-mortem examinations. It was pointed out that apart from the characters of the articular lesions there were conspicuous differences in the more widespread constitutional disturbances associated with the two diseases. Dr. Garrod maintained that osteo-arthritis could not be regarded as merely the later stage of rheumatoid arthritis; that since either disease was met with at all ages it could not be assumed that the distinctive features were due to the age of the sufferer, and he further maintained that in cases in which articular lesions of both kinds were simultaneously observed in the same patient careful inquiry afforded evidence that the two diseases were running concurrently. In conclusion, he pointed out that it was of much practical importance that the question of the identity or otherwise of osteo- and rheumatoid arthritis should be settled, since upon the answer to it would depend not only diagnosis but also prognosis and the treatment employed.—Dr. LATHAM referred to the theory which he had advanced in THE LANCET in 1901 (Vol. I., p. 998)—that rheumatoid arthritis was due to irritative and destructive lesions located in the spinal cord, and specially in the cervical and lumbar enlargements. He suggested that these lesions were due to irritative impulses starting either in the course of the afferent fibres or in the brain itself. Arguing from this theory, he claimed that treatment should be directed to the abatement of the spinal mischief, and that probably this could be most effectively done (the exciting cause being removed) by cupping or blistering the spine.—Mr. WILLIAM ARMSTRONG (Buxton) considered that if a specific bacillus originated the disease, vaccines and serums which had been used would have shown some definite results, whereas, so far as he could learn, they had proved inert. He strongly supported the view laid down by Dr. Latham—viz., that with the exception of gonorrhœal, strumous, and direct septic arthritis, all cases of this trouble were connected with defective nerve nutrition of the joints: that the nerve centres were apt to be disturbed by various reflex sources of irritation, such as gastro-intestinal toxins, utero-ovarian disturbances; oral, nasal, and pharyngeal irritation; and local traumatic conditions. Judged by clinical results he found this theory worked out well, for when the sources of reflex irritation were sought for and dealt with, and when counter irritation at each side of the spinal joint centres was steadily and systematically carried out, the most gratifying results had been obtained in a large number of cases. He found that the drastic treatment advocated by Dr. Latham was badly borne by many patients, so he now applied the electric cautery after a preliminary anæsthetic ionisation with guaiacol and cocaine, which made the application of the cautery almost, if not quite, painless.—Dr. SEPTIMUS P. SUNDERLAND referred to the curious frequency of arthritis deformans in women, as compared with men. He stated that Oliver Sunderland of Bexley believed this frequency was accounted for to a great extent by the

[1] This paper was published in full in THE LANCET, April 9th, p. 997.

fact that women possess a vagina and uterus wherein germs which can produce the disease may often lurk unsuspected and undiscovered; and that when a vaginal, cervical, or uterine lesion coexists the incidence of the disease is favoured. He (Oliver Sunderland) had been led to this belief by the fact that during the past five years he had treated a large number of cases of arthritis deformans in women and claimed improvement in nearly all, and cure in a few, of those cases in which he had found and treated vaginal, cervical, and uterine lesions, and was convinced that in those cases the arthritis was dependent on the vaginal, cervical, or uterine lesions attacked by some unknown microbe. (He had noticed that a large majority of the patients he had treated had very dark hair and dark grey eyes.) He (the speaker) concurred with these views as offering one good reason for the frequency of arthritis deformans in women. They accorded with his own views published in 1898 that gonorrhœal arthritis, contrary to the usually accepted opinion, was more common in women than in men.—Dr. LLEWELLYN JONES (Bath), in his reply, dealt with the various objections brought forward by those who contended that no sharp line could be drawn between rheumatoid arthritis and osteo-arthritis. He said the gist of opposing argument appeared to depend upon the existence of transitional forms whose nature and significance could be more conveniently discussed under two headings: firstly, in regard to the comparatively rare instances in which the lesions of both diseases were to be found overlapping in one and the same individual, examples of which had been reported by McCrae and others. The mere coexistence of the two arthritic affections did not necessarily imply identity, and in his opinion this occasional occurrence did not justify us in regarding them as anything more than instances of the overlapping of two otherwise distinct diseases. Secondly, those cases in which an unusual amount of new bony proliferations developed in joints of rheumatoid arthritis could not be regarded as evidence of the transition of rheumatoid arthritis into osteo-arthritis inasmuch as the osseous outgrowths in the former differed in nature—being inconstant in their presence, inconsiderable in size, and spicule-like in shape. Finally, both these diseases, apart from their articular lesions, possessed each of them a distinctive clinical facies, and in order to prove their transition into each other it would be necessary that a rheumatoid patient should put on the general clinical aspect of an osteo-arthritis—in other words, that the emaciated rheumatoid should assume the appearance of the well-nourished and but too often obese osteo-arthritic. He profoundly hoped that the occurrence of these transitional cases (so-called) would not be permitted to impair their clear definition of the essential distinctness of these two diseases, inasmuch as such confusion must inevitably react unfavourably upon the success of treatment essentially different in both these lamentable maladies.

Dr. H. E. LEIGH CANNEY (Assouan) then read a paper entitled "The Climate of Egypt and North Africa and its Influence on Disease." He said that the chief features of desert air were warmth, extreme dryness imparting an exhilarating effect, great purity, and strong sunlight, wide range of temperature from the hot part of the day to the cool evening, but always constant and never presenting sudden variations. The prejudicial effects of the neighbourhood of cultivation and irrigation in modifying the desert climate were demonstrated, and the advantages of the positions of Assouan and Helouan in this respect were pointed out. The group of resorts close to the Mediterranean, including Algiers, Morocco, Tunis, and Alexandria, were shown to have marine climates, very little under the influence of any desert conditions. The climate of Algiers closely resembled that of Malaga, Sicily, and Southern Greece, all situated on the same latitude, from December to March the weather being that of an English autumn with twice the sunshine and rain, being colder than the Egyptian resorts and less dry than the Riviera. Biskra was on the northern fringe of the Sahara, not far enough inland to escape the influence of the Mediterranean. It had a rainfall resembling Alexandria (from 6 to 8 inches). It was situated in a latitude of 4° north of Alexandria, and therefore some hundreds of miles north of Cairo, its climate being colder than Algiers by 3°, than the northern resorts of Egypt by 7°, and therefore far less advantageous for the treatment of the diseases commonly sent to Egypt, being also less dry. The action of the dryness and warmth of the desert on the various organs was considered, especially in relation to the diseases rheumatoid arthritis, Bright's disease, asthma and pulmonary diseases, phthisis and chronic bronchitis, cases of mental strain associated with gout and arterio-sclerosis, neuritis, neurasthenia and toxæmias; and it was specially urged that cases of rheumatoid arthritis and persistent albuminuria after various infections should be sent to Egypt as early as possible before serious damage was done. Owing to the excessive dryness of the climate the rate of cooling became too rapid in the desert after exercise unless special precautions were taken, and unless this was strictly attended to serious harm was done. Many of the illnesses so much benefited by the Egyptian climate, especially the pulmonary and renal cases, were best treated in hotels, and should travel up the Nile by train rather than steamers or dahabeahs. The northern resorts in Egypt, near Cairo, Mena House, and Helouan were considered not warm enough in winter, especially for part of December, January, and February, to obtain the best results in rheumatoid arthritis, many pulmonary and renal cases. Assouan was the driest health resort in the world, 28·2 per cent. drier than Mena, 14·6 than Helouan, and 11·3 than Luxor; and this added a great bracing quality to the climate. The best time to arrive in Egypt was early in November, staying at Mena or Helouan, and not in Cairo, and then if it has been considered that special warmth and dryness are desirable, they must be sought in Upper Egypt after the middle of November and until the middle or end of March, when the Northern resorts are available until the end of April or into May.—Dr. T. F. GARDNER (Bournemouth) proposed a vote of thanks to Dr. Canney for his paper, and the PRESIDENT expressed great regret that time did not permit of a full discussion of so interesting and important a paper.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases.

A MEETING of this section was held on April 22nd, Mr. W. MILNER BURGESS being in the chair.

Dr. ROBERT HUTCHISON exhibited three cases of Oxycephaly. The children were aged respectively 1, 5, and 4 years. They all showed the typical oxycephalic head. Two had exophthalmos, while the other had the eyes wide apart and divergent. All three showed congenital deformity of the fingers.—The cases were discussed by Dr. H. MORLEY FLETCHER, who gave it as his opinion that the condition was due to a developmental defect, and not secondary to an abnormality of the brain.—Dr. G. A. SUTHERLAND agreed with this view of the cases and Dr. F. PARKES WEBER also spoke.—Dr. HUTCHISON, in replying, said that he also believed the condition to be due to bone maldevelopment rather than to a brain condition.

Dr. HUTCHISON also showed a case of Speech Defect in a child aged 7½ years. The child had never talked, but there was reason to believe that the child was not a deaf mute, but could hear to some extent.—This case was discussed by Dr. G. E. SHUTTLEWORTH and Dr. FREDERICK LANGMEAD.

Dr. LANGMEAD exhibited a case of Congenital Scoliosis. The patient was a girl, aged 10 months, who had a sharp bend to the left in the dorsi-lumbar region of the spine. A skiagram showed this to be due to an additional wedge-shaped bone interposed between the last dorsal and first lumbar vertebræ of congenital origin.

Dr. LANGMEAD also showed a baby with Blue Patches on the Buttocks and Lumbar Region. He pointed out that this pigmentation was a racial characteristic in Japanese and half-caste babies. There was some doubt as to the nationality of the child's grandfather.—The case was discussed by Dr. G. PERNET, Dr. SUTHERLAND, and Dr. MORLEY FLETCHER.

Dr. R. H. MILLER showed a case of Juvenile General Paralysis with loss of Knee-jerk. The patient was a boy, aged 14 years, who exhibited the characteristic symptoms. There were no signs of inherited syphilis, but a positive serum reaction had been obtained.

Dr. MILLER also showed a case of Lymphadenoma starting at the twenty-fifth month. The child was aged 3 years. Six months previously a gland, which on microscopical examination appeared to be lymphadenomatous, had

been removed from the neck. There had been a steady increase in the size of the glands. The white cells in the blood numbered 6800 and showed a slight excess of lymphocytes.—Dr. HUTCHISON discussed the case.—Dr. SUTHERLAND pointed out the great difficulty of diagnosing between this condition and tuberculosis.—Dr. F. J. POYNTON stated that cases of congenital syphilis were sometimes mistaken for lymphadenoma.

Dr. L. G. PARSONS showed a case of Congenital Acholuric Jaundice. The patient, a boy aged 8 years, had been yellow from birth. There was no other case of jaundice in the family and no specific history. The spleen was uniformly enlarged. The temperature was 100° F. and the blood count showed marked anæmia. Hæmoglobin 28 per cent.—Dr. POYNTON and Dr. PARKES WEBER discussed the case.

Dr. PARSONS also showed a case of Inherited Syphilis.

Mr. J. HOWELL EVANS showed a case of Sarcoma of the Right Kidney in an infant.

Dr. LANGMEAD read a paper on 80 Consecutive Cases of Wasting Infants Fed on Undiluted Citrated Milk.—Dr. E. I. SPRIGGS, Dr. POYNTON, Dr. H. R. CARTER, and Dr. MILLER discussed the paper.

ODONTOLOGICAL SECTION.

Odontoceles.—Suppuration in the Maxilla.—Neuralgia due to Impacted Lower Wisdom Teeth.—Exhibition of Cases.

A MEETING of this section was held on April 25th, Mr. WILLIAM HERN, the President, being in the chair.

Mr. A. HOPEWELL-SMITH read a paper entitled "Two Odontoceles and Some Other Cysts." He described two remarkable and unique cases of malformation of the teeth which had been retained, unerupted, in the jaws in one case of a man aged 31 years, in the other of a medical man aged 41 years. These had given risen to unilocular cystic tumours of the jaws, which, differing from anything previously observed and recorded by pathologists, had, in one instance, been diagnosed as a myeloid sarcoma of the superior maxilla. Neither could be classified as examples of dentigerous cysts or follicular odontomes, and Mr. Hopewell-Smith therefore proposed for them the new terms of sub-capsular and extra-capsular odontoceles respectively. One specimen showed absence of portions of the crown of a tooth, the other additions to its crown, in the form of a calcified capsule—the dental sac or follicle. Epithelium lined the walls of both cysts. Incidentally it was pointed out that the gum margins near the necks of the teeth are freely supplied with mucous glands on the *inner* palatal aspect, and that they are absent over the *external* surface of the alveolar processes. The life-history of the dental follicle, or capsule—a more scientific term—was briefly narrated and the opinion expressed that the contents of dentigerous cysts owe their origin to the breaking down of the stellate reticulum cells of the enamel organ. The paper was fully illustrated by means of pathological preparations, lantern slides, microscopical slides, diagrams, and blackboard drawings.

Mr. C. SCHELLING gave a casual communication on Two Cases of Suppuration in the Maxilla and a Case of Neuralgia due to Impacted Lower Wisdom Teeth.

Mr. HERBERT TILLEY showed Two Cases of Suppurating Dental Cysts Invading the Antrum.

Mr. W. RUSHTON exhibited a Case of Painful Attrition.

MEDICAL SOCIETY OF LONDON.

Gastroptosis.

A MEETING of this society was held on April 25th, Dr. SAMUEL WEST being in the chair.

Mr. F. S. EVE read a paper on the Surgical Treatment of Gastroptosis, being an analysis of a series of 20 cases, with special reference to the results of operative treatment. He said that the symptoms *associated with* gastroptosis were those common to several other functional and organic affections of the stomach. Hence, the diagnosis rested on physical examination and on a process of exclusion, the culminating point of which was in many cases an exploratory laparotomy. The patient suffered with severe chronic dyspepsia, often of long standing. In two of his cases the symptoms had lasted 20 years, in one for 12, and in two for 10. There were flatulent distension, a sense of fulness, and pain after food referred to the epigastrium, and sometimes radiating under the right costal margin and to the scapula. The pain came on at various periods after food, usually early, but occasionally after a longer period, even up to three or four hours. Vomiting was often present, and in exceptional cases was incessant. The symptoms might be more or less persistent; but commonly the sufferers were subject to periodic attacks or exacerbations of the symptoms which led to their admission to hospital on several separate occasions. The pain was prone to be made worse by standing or walking about after a meal. During the exacerbations there was in many cases distinct superficial and deep tenderness over the epigastrium. The diet was usually by force of circumstances restricted. Meat was often avoided, and the worst cases restricted themselves to milk, eggs, and such light diet in small quantities. Hæmatemesis was present frequently; it existed in 9, and perhaps 10, out of his 20 cases. In 7 of these it was considerable in amount—a teacupful or more; exceptionally, it was frequent and small in quantity. The symptoms associated with gastroptosis were in many instances so like those of gastric ulcer that the latter could only be excluded by a laparotomy. Allusion had been made to the frequency of hæmatemesis—i.e., in nearly 50 per cent. of his cases. Pain and vomiting after food, superficial and deep tenderness over the epigastrium, and hyperæsthesia of the skin to the right of the lower dorsal spines *might* all be present. A most important point of distinction was that the acidity in gastroptosis was rarely increased, and was sometimes low. Free hydrochloric acid was, in one or two cases of long standing, entirely absent. When a youngish woman was referred to him with suspected gastric ulcer whose acidity was at or below normal he always examined carefully for gastroptosis, especially if the lower part of the thorax was elongated and narrow. Those cases formed a distinct type. The results of gastropexy were as follows: Of the 11 cases two had only recently been operated on, but were relieved of their symptoms while in the hospital. One was quite well 12 months after the operation, but must be excluded because calculi were removed from the common bile-duct at the same time that gastropexy was performed, and the symptoms were probably largely due to cholelithiasis. Another patient became melancholic shortly after the operation, was sent to an asylum, and had since been lost sight of. That left seven cases. Of these, six were completely cured; three of them reported themselves between one to four years after the operation, and three between three and nine months afterwards. The remaining patient, operated on 13 months ago, was a neurasthenic maid-servant aged 32. She was quite well for some time after the operation, but returned to hospital at the end of a year owing to occasional vomiting and return of pain; but her symptoms entirely subsided while she was in the hospital, and she was able to take ordinary food. Before the operation the iodipin reaction was obtained in three hours, indicating that the motility of the stomach had improved. The results of gastro-jejunostomy were as follows: Seven cases were treated by this method and they were mostly his earlier ones. In three of them there was marked dilatation of the stomach in addition to gastroptosis and two of these had also hæmatemesis. In three other cases hæmatemesis was a conspicuous symptom. Three of the patients were definitely neurasthenics; but gastro-jejunostomy was performed because in one case there was distinct dilatation and in the two others incessant vomiting with hæmatemesis. Of the seven cases four were cured; of these two reported themselves 20 months and seven years respectively after the operation and two eight and three months respectively. The three remaining cases (all neurasthenics) were slightly improved. None of the cases with hæmatemesis had any recurrence. In fact he had not yet seen recurrence of hæmatemesis after gastro-jejunostomy. The stoma of the gastro-jejunostomy probably acted as a safety-valve and prevented the distension of the stomach, which was one of the chief causes of the hæmorrhage. The two cases treated by Duret's method were improved at first, but ultimately relapsed more or less completely. In one of them gastropexy was subsequently performed with excellent results. Mr. Eve's conclusions were that an operation on Beyea's plan, as modified by him, was indicated in the majority of cases of gastropexy which were not amenable to medical treatment. Gastro-jejunostomy should be avoided,

but might be necessary in certain cases of gastroptosis with dilatation and atony and for the relief of hæmatemesis.

Dr. ROBERT HUTCHISON read a paper on the Principles of Treatment in Gastroptosis. He said that the first point upon which it was necessary to lay emphasis was that gastroptosis was not really in itself a disease and in many cases called for no special treatment. It must have happened to everyone present to discover the existence or displacement of the stomach in the course of the routine examination of a patient who had made no complaint of gastric symptoms. It would be found, he thought, in such cases that the dislocation of the stomach had been induced, so to speak, accidentally, most often, perhaps, as a result of weakening of the abdominal wall in consequence of repeated child-bearing. It was true that in a case of that sort there might be a greater or less degree of "pendulous belly," which might cause some mechanical inconvenience, but apart from that, and assuming the patient to be otherwise vigorous, there need be no symptoms which could be directly referred to the abdominal organs. In these cases gastroptosis demanded no special treatment, but he believed he might go further and state that in no circumstances did mere displacement of the stomach, considered by itself, make such demands and that it was only because of its tendency to be associated with two other morbid conditions that gastroptosis came within the cognisance of the physician at all. Those morbid conditions were—(1) a general state of neurasthenia, and (2) functional disorder of the stomach and intestines. In the treatment of the neurasthenia which accompanied, if it did not underlie, most cases of gastroptosis, their most effective means was a well-planned rest cure. Their object must be to improve nutrition or, in the words of Weir Mitchell, to make fat and blood. At the outset one *a priori* objection to that plan must be faced. To improve nutrition the patient must be overfed, but would his debilitated stomach permit of that being done? Was there not a danger of over-distending it and of increasing any atonic dilatation which might be present? In practice he did not think that objection held. Provided the feeds were not too large and the food suitably selected and prepared, such a result need not be feared, and as the general "tone" of the patient improved one found that the digestive power improved *pari passu*. Furthermore, one found that patients with gastroptosis who suffered great digestive discomfort whilst they were going about lost most of their symptoms so soon as the recumbent position was adopted, and had no difficulty in managing a full diet. *Per contra*, there was, he was sure, a real danger in cutting down the diet in those cases in order to quiet the complaints of the stomach. By so doing one merely suppressed a symptom whilst really aggravating the complaint, for the consequence of such a course was that the nutrition became still further impaired and the neurasthenic state exaggerated. Here, as always, in prescribing dietetic rules one must not sacrifice the whole body for the sake of any one member of it, or, in other words, one must diet the patient and not the disease. Of the accessory measures in the rest cure—massage and electricity—most importance was to be attached to massage. It had a threefold use. It promoted general nutrition and the laying on of fat; it improved gastric and intestinal tone and it strengthened the abdominal wall, all of which were cardinal objects of treatment. The help of electricity could, in his judgment, be dispensed with, but to that point he should return again. Concerning the use of drugs in combating the neurasthenic state there was little to say; the bromides were perhaps the most generally useful and would usually be called for at some period in the case. Strychnine, though often ordered, was frequently injurious. Of such agents as the hypophosphites and glycerophosphates he had a low opinion. Iron might be helpful if there was pronounced anæmia, but that was an exceptional occurrence, and the state of the digestion would not always permit of its exhibition. In such cases arsenic might come to their assistance. In ameliorating the general asthenic condition of the patient by a rest cure they did much to correct any loss of tone or motility in the stomach. There was experimental evidence also that massage of the stomach stimulated its movements and so aided its motility. As to the value of electrical means he was not convinced. He believed that there was no satisfactory evidence that the application of electricity to the abdominal surface had any effect upon the stomach at all, but if any form of it was to be tried the sinusoidal current was probably that which offered the best chance of success. Drugs also, contrary to what might be expected, were probably of little help. They stood much in need of some drug which would act upon the musculature of the stomach in the same specific way as digitalis did upon that of the heart or ergot upon that of the uterus. Physostigmine was, perhaps, the one from which on pharmacological grounds most might be expected in that direction, but its use was open to practical objections and it had never been generally adopted. Strychnine might possibly increase the tone of the stomach, as it did that of most unstriped muscle, but the results it yielded were not brilliant and its action upon the nervous system was sometimes disadvantageous. He was not sure that aloes had not a stimulating effect upon the movements of the stomach as it had upon those of the colon. He had an impression that it had, but it was difficult to adduce any convincing clinical evidence of such action, and he was not aware whether it had been tested experimentally. The means to be adopted in the correction of disorders of secretion in cases of gastroptosis differed in no respect from those in use in ordinary cases of functional dyspepsia. Over-secretion was the commonest fault, and was to be met by the free administration of fats and by the judicious use of bismuth and the earthy carbonates. The bromides were also of service here, as they seemed to deaden the reflex excitability of the stomach. In the treatment of hyperæsthesia of the displaced stomach there was no measure equal in value to the use of local moist heat in the form of poultices or fomentations, and whenever there was general epigastric tenderness such means might be usefully employed during the first week of the rest cure. Gastric sedatives such as bismuth, bromides, chloroform, and even, in extreme cases, opium were also of service. Should the disorder of function have induced or be complicated by some degree of gastritis, as evidenced by a foul tongue, impairment of appetite, and nausea, it was advisable before treating the underlying disorder of secretion or motility to allay the catarrhal symptoms. The diet in such circumstances should consist of milk only, and judicious use should be made of those well-tried drugs—mercury and rhubarb. Unquestionably patients with enteroptosis derived great comfort from any effective means of supporting the abdominal viscera, but it was very doubtful whether that was the result of any actual pushing up of the displaced organs. Such support gave relief from those feelings of sinking, emptiness, and exhaustion which were amongst the most bitter complaints of the gastroptotic, but those sensations were probably due to lessened intra-abdominal tension and a tendency to pooling of the blood in the splanchnic area when the erect position was assumed. The relief of those symptoms was, none the less, a legitimate object of treatment, and hence the provision of some form of abdominal support had always to be considered. Now, it had been truly remarked that the best belt was a firm abdominal wall, and hence their efforts should be directed to restoring the tone of the abdominal wall and to thickening it by the deposition of a substantial layer of subcutaneous and extra-peritoneal fat. The rest cure, if successful, should achieve the second of those objects, especially in men, in whom the deposition of fat in the abdomen seemed to take place more easily than in women. By increasing the amount of "packing" in the abdominal cavity intra-abdominal tension was increased and the tendency to undue mobility of the viscera restrained. As regards the development of the abdominal muscles, reliance must be placed upon massage and the practice of "abdominal exercises." He thought it would be generally agreed that the ideal abdominal belt remained yet to be invented. It was simple enough to point out what was wanted—the exercise of pressure from the lower part of the abdomen upwards and somewhat backwards—but the difficulty was to carry that principle into practice. He concluded by enumerating three things which he thought should not be done: First, patients with gastroptosis should not be over-dieted—which, of course, was just the reverse of being over-fed; secondly, their stomachs should not be washed out; and thirdly, they should not be operated upon.

Dr. R. H. SCANES SPICER discussed the subject of gastroptosis from the point of view of its causation through the action of the diaphragm not being centrifugal. His method of treating the condition was by means of physical culture. He declared that by assuming the correct position with a

straight spine the diaphragm would act centrifugally, resulting in rectification of the condition so as to render operative measures unnecessary.

Dr. A. F. HERTZ emphasised the importance of distinguish ing between two tpyes of gastroptosis, one which occurred as part of general visceroptosis and the other consisting of remarkable cases in which gastroptosis alone was present.

Dr. F. PARKES WEBER pointed out that in orthostatic albuminuria and in gastroptosis there was one condition which was common to the two abnormal states, and that was that in both instances when the patients lay down the symptoms disappeared or became very much diminished. He would like to have the matter investigated.

Dr. WEST said that the utility of washing out the stomach in cases of gastroptosis was denied, but there was no doubt that these cases were benefited by removing accumulations of fluid from the stomach so as to keep that organ empty.

The meeting concluded after Mr. EVE and Dr. HUTCHISON had replied.

HARVEIAN SOCIETY OF LONDON.

Surgeons, some Mortals, and the Climacteric.—Treatment of Indigestion.

A MEETING of this society was held on April 14th, Dr. M. HANDFIELD-JONES, the President, being in the chair.

Dr. LEONARD WILLIAMS read a paper on Surgeons, some Mortals, and the Climacteric. As an excuse for the "mere physician" dealing with the subject of the climacteric Dr. Williams indulged in some genial banter on the prominent position now occupied by operative surgery. At dinner parties personal experiences of the guests formed the chief topic of conversation. The text-books were given up to the subject. In works on gynæcology a subject like the climacteric was crowded out by details of operative surgery. Finding no place in purely medical text-books the menopause had become a "veritable maiden aunt of practice." After a brief description of the disturbances usually observed at this epoch, he called attention to three causes to which some of them might be due—eye strain, disturbances of blood pressure, and thyroid inadequacy. The first, of course, was a common condition at this time of life, due to slight errors of refraction which were frequently overlooked but should always be sought for; even when recognised these minor errors were often minimised, oculists themselves not realising their important influence on the general health, and patients generally objecting to beginning glasses. These objections should be tactfully overridden and, wherever present, errors of refraction corrected. Vaso-motor phenomena might be said to be normal to the climacteric. The more common hypertension was relieved by the hæmorrhages so frequently present, and these should not be unduly repressed. The rarer hypotension, the symptoms associated with which he described, was best treated by ergot, strychnine, and pituitary extract. But its presence should first be demonstrated by a reliable manometer lest disaster befall. Speaking of thyroid inefficiency, he described a group of symptoms or signs frequently present at this age period which, while falling a long way short of myxœdema, to his mind indicated a certain degree of deficiency of the secretion. When this sub-thyroidic syndrome was present he prescribed thyroid gland extract with much benefit, but not in the usual doses; half a grain twice a day, possibly increased, sufficed. He mentioned ichthyol as one other drug which he had quite empirically learnt to place reliance on in the treatment of the subjective symptoms of the menopause generally.—The paper was discussed by Mr. W. H. CLAYTON-GREENE and Mr. ERNEST CLARKE.—The PRESIDENT remarked on the frequency with which the menopause was held responsible for symptoms. He supported blood-letting in suitable cases. He did not agree that thyroid inefficiency was of importance as a cause of symptoms during the climacteric, and pointed out that in these days numbers of women treated increasing obesity with thyroid extract and yet suffered from the usual symptoms at the change of life. He considered that ichthyol acted as an intestinal antiseptic.—Dr. LEONARD WILLIAMS replied.

Dr. E. I. SPRIGGS read a short paper upon the Treatment of Indigestion. He reviewed the functions of the stomach which might be in abeyance or exaggerated, and pointed out that unless an exact diagnosis was made the appropriate treatment could not be applied with certainty. Certain forms of indigestion might often be recognised from the symptoms without an examination of the stomach contents, such as hypersecretion of gastric juice, and in some cases motor insufficiency. From a review, however, of 425 cases of dyspepsia, of which he had taken notes, it was concluded that in the majority of these—namely, 364—an exact diagnosis was not to be made from the symptoms and physical examination of the stomach alone. The physician might form a definite view, but analysis of the stomach contents would show that this view was often wrong. Nevertheless, in a large proportion treatment had been successfully applied. He much preferred, whenever possible, to make an exact diagnosis by an examination of the contents of the stomach or of vomited matter. Although the procedure of withdrawing material from the stomach was an extremely brief one, nevertheless many patients, and not unnaturally, objected to the discomfort of passing a tube. Treatment founded upon experience might be applied first in these, and would often be unsuccessful. The earliest step was to remove, when possible, the circumstances causing the dyspepsia. These were discussed in the following order—overwork, irregular meals, insufficient or septic teeth, errors in diet, alcohol, tobacco, exposure to cold, and anxiety leading to neurasthenia. A large number of cases might be relieved by dealing with the cause. Of medicines, the review of the notes of the 425 cases above mentioned, in which a large number of medicines had been used, showed that benefit had resulted most frequently from one of two kinds of medicines—namely, alkali and a carminative, such as ginger, an hour or an hour and a half after a meal, or when the discomfort came on; or bismuth carbonate in doses of half a drachm or more before meals. If success did not follow simple measures the stomach contents should be obtained after a test meal. The microscopical and chemical examination of this material was referred to, and it was detailed how a diagnosis of such conditions as chronic gastritis, hypersecretion, or motor insufficiency could be made. The course of treatment was then outlined. Dr. Spriggs concluded by pointing out again how much more likely it was that treatment could be successfully directed when an accurate knowledge of the cause of the symptoms was obtained.—Mr. E. PARKER YOUNG was disappointed at the paucity of remedies mentioned by Dr. Spriggs and spoke of the value of charcoal and creosote.—Dr. E. C. YOUNG thought that the unpleasantness of passing the stomach tube was exaggerated. He considered the best time to wash out a dilated stomach was before the evening meal. He approved of the plan of giving fluids an hour before meals and of giving proteid food in cases of hyperacidity.—Dr. LEONARD WILLIAMS did not consider that tobacco was a cause of dyspepsia. He thought nowadays there was much nonsense talked about diet, and the stomach was pampered. He mentioned eye-strain and nasal obstruction as additional causes of dyspepsia.—Dr. SPRIGGS replied.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 20th, Dr. A. Fulton, the President, being in the chair.—Mr. R. G. Hogarth showed a boy admitted three weeks ago into the hospital with symptoms of Internal Hæmorrhage. At the operation the spleen was found to be ruptured and was removed. The boy made a splendid recovery.—Mr. Kenneth Black showed a case of Wry-neck successfully treated by removing the sternal head of the sterno-mastoid and uniting this to the clavicular portion.—Dr. J. A. Robinson, in opening a discussion on "Is Craniotomy Justifiable?" reviewed the history of instrumental delivery. Owing to the extremely high mortality with which Cæsarean section used to be attended, craniotomy became the operation of choice, and some authorities declared that it was nearly as safe as normal labour. However, modern methods had succeeded in reducing the mortality of Cæsarean section to 6 per cent. Its advantages were: its ease; the fact that a healthy, full-term child was presented to the mother; the mother could, if necessary, be sterilised; and altogether it provided the best results for the mother. Perforation should never be performed on a living child. With a conjugate of two and three-quarter inches symphysiotomy or pubiotomy provided alternate methods. The

writer quoted 20 cases of Cæsarean section with three deaths, but he pointed out that the fatal cases occurred in private practice and dirty and septic surroundings. He urged, therefore, that these cases should be diagnosed early and removed to some hospital or institution. In his opinion craniotomy was a reflection on the management of difficult labour.—Dr. A. C. Reid agreed that when the child was living and circumstances were favourable Cæsarean section was the operation of choice. But as a Poor-law medical officer he was often called in by midwives when labour had already lasted 24 hours and the woman was exhausted. Prompt removal to hospital in such cases was difficult, and the general practitioner was forced to rely on craniotomy. His own experience was not encouraging, as he had had three deaths in five cases, two from ruptured uterus and one from shock. Still, he held that craniotomy was justifiable where a living child was impassable and considered it to be the operation of election (1) where the child was non-viable and the mother's condition was urgent; (2) in the case of monstrosities; and (3) where the fœtus was exceptionally large, and especially if it was dead. He urged that homes should be established where difficult labours could be properly watched.

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.—A meeting of this society was held on April 15th, Dr. William Grant being in the chair.—Dr. J. H. Nicoll, in showing two infants recently treated by operation for Congenital Hypertrophic Stenosis of the Pylorus, pointed out that this condition is comparatively common. In its earlier stages its treatment is necessarily dietetic, and such treatment cures a number of the slighter cases, though it is probable that amongst the recorded cures have been included cases in which the diagnosis has been doubtful. For cases of more severe degree dietetic treatment is useless, and its undue prolongation destroys the chances of operative success. For well-marked hypertrophic stenosis operative treatment is necessary, and, undertaken before exhaustion or emaciation has become pronounced, gives satisfactory results.—Dr. W. T. Ritchie and Dr. J. M. Cowan gave a lantern demonstration on "Coupled Rhythms of the Heart" (pulsus bigeminus); and Dr. Cowan showed a convenient form of Polygraph.—Dr. A. J. Ballantyne showed illustrations of two cases of Foreign Body in the Interior of the Eye. The cases were almost identical in their essential features, but one was quite recent, while the other had received his injury 15 years ago. In the former there was a small corneal cicatrix and a perforation of the iris below the pupil. When first seen a few days after the accident there was considerable opacity of the lens. This rapidly cleared up, and a few days later the foreign body, probably a chip of metal, could be seen impacted in the retina. The object was also detected by radiography, but the large electromagnet failed to move it. The older case presented a similar perforation of the iris, a small amount of opacity of the lens, and a foreign body in the same situation as in the other case, but in spite of clear transparent media the vision was very defective. It was considered that the deterioration of vision was due to the chemical action of the metallic particle on the retinal elements, and that the condition of the older case might be taken as an indication of the probable course of events in the more recent one.

ROYAL MICROSCOPICAL SOCIETY.—A meeting of this society was held on April 20th. Mr. F. R. Chopping, assistant in the Clinical Laboratory at the Westminster Hospital, exhibited specimens of bacteriological culture media in dry concentrated form (provisional name "Solmedia"). As they are light and of small bulk, they can be sent by post at cheap rate. They do not deteriorate, have hitherto kept extremely well, and will probably do so for quite a long time; hence they will be invaluable for work in warm climates, especially tropical. The method of using the media, which is quite simple, is as follows: 5 cubic centimetres of water are to be added to a given weight of solmedium in a test-tube; the test-tube is then placed in a water bath for about 30 to 45 minutes, and afterwards allowed to set in the required position. In this way a tube of sterile media is cheaply and easily prepared. Samples of unused "solmedia" culture tubes were exhibited and also cultures of various organisms in various media, as well as uninoculated tubes of media. This method of producing dry concentrated media, which Mr. Chopping has elaborated after about two years' work, may lead to important results.

Reviews and Notices of Books.

A Text-book of Nervous Diseases. By WILLIAM ALDREN TURNER, M.D. Edin., F.R.C.P. Lond., and THOMAS GRAINGER STEWART, M.B. Edin., M.R.C.P. Lond. London: J. and A. Churchill. 1910. Pp. 607. Price 18*s.* net.

THE aim of the authors, as expressed in their preface, has been to provide the practitioner and senior student with a short and practical account of the diseases of the nervous system, based not so much on the model of larger text-books as on the results of their own practice and experience. They have produced a thoroughly sound and serviceable text-book, in which much of proven value from the teaching standpoint has been incorporated. One of the features of the volume is the tables of differential diagnosis, unusually large and complete, whereby the chief symptoms and signs of diagnostic import in various diseases can be seen at a glance and their relative significance appreciated. Throughout the book the authors have steadily adhered to the ideal combination, from the working student's standpoint, of conciseness and accuracy, and they are to be congratulated on the achievement of their purpose. We know of no other text-book of similar size which contains so much matter presented in a readable fashion, embodying the results of wide clinical experience and not a little that we have not found elsewhere.

An introductory chapter on the anatomy and physiology of the nervous system is followed by a scheme for the examination of patients suffering from nervous disease. The special senses, cranial and peripheral nerves, receive suitable consideration; then comes a large division of the volume devoted to the diseases of the brain. The chapter on intracranial tumours is excellent, and the descriptions of the varying factors in their localisation are lucid and well expressed, but a table of differential diagnosis between certain groups might, perhaps, have been furnished. In the chapter on intracranial vascular lesions, which is otherwise good, we can find no adequate reference to the different types of crossed hemiplegia, types that are both of clinical interest and localising importance, and we should like to see this remedied in a subsequent edition. The diseases of the spinal cord are preceded by a sketch of the functions of the normal cord and are handled methodically and minutely. Under the heading of general diseases of the nervous system is an excellent account of the varieties of syphilitic and parasyphilitic nervous disease and of disseminated sclerosis, subacute combined degeneration of the spinal cord, and other affections. In the chapter on acute poliomyelitis the statement that "it is known to occur in epidemic form, several well-authenticated instances of which have been recorded," may be a little misleading, in view of the fact that epidemics involving thousands of cases have been raging in various parts of the world in the last few years, and much more is known now than formerly of the nature of the morbific agent. It is a question whether Landry's paralysis is not closely allied to poliomyelitis. The chapters on familial diseases of the nervous system, on hysteria, neurasthenia, psychasthenia, epilepsy, and the tics leave nothing to be desired. The authors regret that the limitation of the size of the book has made necessary the omission of certain disorders usually described in treatises upon the nervous system, such as exophthalmic goitre and acromegaly.

The volume is excellently printed, and its value is enhanced by the inclusion of about 200 admirable clinical and pathological photographs and diagrams. There are some misprints (notably one on p. 151) and the inaccurate rendering

of various proper names might be corrected in a subsequent edition. We think there should be an assured place for such a text-book as the one under review—an up-to-date, compact, and methodical volume in which the needs of the practitioner and student have been kept in mind, and in which they will find trustworthy information that comes, as we have already said, not from a mere abridgement of large treatises, but from a judicious application of personal observation and experience.

Studies in the Psychology of Sex. Vol. VI.: Sex in Relation to Society. By HAVELOCK ELLIS. Philadelphia: F. A. Davis Co. 1910. Pp. 656. Price $3 net.

THOUGH it is impossible to estimate the value of this volume as detached from the five smaller ones of its series, it stands alone among them as a larger study of the subjects to which Mr. Havelock Ellis has devoted his life. In some of his earlier writings the author confined his aspect too carefully to the most advanced modern views of the subject of sex and sexual relations, and was not quite fortunate in the manner of their presentation. The result was to place him in unpleasant opposition to unlearned and unscientific thought and a judicial authority to which that thought appealed. In the case of this volume there is no chance of such an appeal. The physiological and psychical details which have necessarily to be handled are treated gravely and soberly. In a historical survey of this wide field it is impossible to avoid details which could be duplicated in the pages of Aretino or Casanova, but the manner of these writers is sedulously avoided.

The author has very wisely decided upon a wide historical survey of his difficult and delicate theme. In our estimation of social problems we are all guided (a few consciously and the remainder unconsciously) by inherited traditions of the past. To comprehend the ideas of the Western world upon the complex questions of sexual relations, marriage, prostitution, enforced chastity, and similar subjects it is essential to have an adequate grasp of Oriental ideas, of the sentiments of the Greek and Roman world, of the teachings of the early Christian churchmen, and of the revolt against that teaching initiated in Provence and rendered popular throughout Europe during the Renaissance. Questions which vexed Origen and Jerome, questions gravely summarised in the pages of Lecky, are profitably and properly recalled in the work before us. Both the matter under consideration and the plenitude of reference will remind the reader of Robert Burton. The resemblance does not stop there; Mr. Havelock Ellis scarcely commits himself to an opinion, and, like the old senior student of Christ Church, he strings references together which support a general view without any violent bias.

The book begins with a broad, quiet survey of the point at which modern thought has arrived on such questions as sexual education, the enlightenment which should be given to boys and girls on this important matter; this is well handled, and the position maintained can hardly be considered as too pronounced. The chapters which follow on "The Valuation of Sexual Love," "The Function of Chastity," and "The Problem of Sexual Abstinence" are excellent essays in historical survey. Full of information, accurate in detail, and free from any suggestion of offence, they present a synopsis of the study of this aspect of human morals. A large space of over a hundred pages is given to the consideration, from both the historical and psychological standpoint, of prostitution. The inferences drawn from modern evidence are, on the whole, sound; the author recognises that information gathered by sentimental enthusiasts from prostitutes is extremely tainted, and that, speaking broadly, poverty is not the most important cause of prostitution. The conditions which have been recently quoted as existing in certain Russian provinces are probably exceptional.

The matter to which exception might be taken is the chapter on the "Art of Love." It is perhaps undeniable that ardent young husbands are apt to be too hasty and too clumsy in the introduction of their wives to the mysteries of the marriage bed; there has been too much reticence on the part of mothers, and the sudden initiation which had no repulsion for Sophia Western might well create an abiding distaste in the cultivated modern girl. For the husbands of highly sensitive brides some teaching in skill and tact may certainly be useful, but it is doubtful if the refinements in the *ars amandi* detailed in this chapter are desirable for general adoption. If dyspareunia occurs occasionally, as it does, on sentimental grounds, the trouble is limited to a few persons; and a widespread contemplation of methods which we find in the pages of Martial or a re-issue of the eighteenth-century editions of the "De Variis Veneris Schematibus" (with cuts) is not to be tolerated; they must inevitably have engendered an undesirable degree of concupiscence in those who came under the influence of such instruction.

With this reservation these studies can be honestly recommended to the medical world and to serious students of social problems. For the volume is what it affects to be—a series of studies, a grouped epitome of the opinions and observations of recognised authorities. If the author occasionally commits the error of dismissing an argument by the mere quotation of a single contemporary opinion, he makes, on the other hand, little attempt to be dogmatic on his own account. Mr. Havelock Ellis has become a scholar in his peculiar field, and has given the dignity of scholarship to a very delicate and difficult subject, and this is the proper method of treatment.

The Morphia Habit and its Voluntary Renunciation. By OSCAR JENNINGS, M.D. Paris. London: Baillière, Tindall, and Cox. 1909. Pp. 492. Price 7*s.* 6*d.* net.

THE author commences the preface to his book with the astonishing statement that "one medical man out of four is a drug *habitué*, usually a morphinist." On p. 62, in a footnote, appears a somewhat similar, but more guarded, remark—viz.: "It has been said that one medical man out of four is addicted to the habitual use of morphia." Neither statement is correct so far as British medical men are concerned, and no evidence is produced to show that continental practitioners suffer to this extent from drug addiction.

Some 87 pages are devoted to a long description of the treatment of a single case. But though there appears to be unnecessary detail the description is instructive. The physician who undertakes the treatment of a morphia *habitué*, if he wishes to satisfy himself and his patient, must be prepared to be at the beck and call of his patient at all hours and to spend much time over the case. Such cases are consequently, in the generality of instances, more suitable for institutional treatment or as resident patients in the house of a medical practitioner. Dr. Jennings advocates gradual drug reduction and the employment of bicarbonate of soda, preferably in the form of Vichy water, sparteine, and the Turkish bath as the three great therapeutic measures in the treatment of this condition—measures which other authorities have tried and which have been found in many hands to be disappointing. It may be that his firm belief in his "therapeutic triad" so affects his patients that the resultant symptoms due to drug withdrawal are relieved by suggestion; for unless there is a dosage difference it is difficult otherwise to account for the diversity of results and opinion. In this condition, as in many others, the personality of the physician

and his faith in the remedies which he prescribes are factors which must be taken into consideration. Dr. Jennings voices the opinion of the majority of those who have studied and have written on the subject when he states that his general experience is "that there is no one remedy or method, that every case is a special study in itself, and that ..... each case must be treated on its own merits."

The book is written by one who is known to be interested in the subject and to have had much experience therein. Dr. Jennings has an intimate knowledge of the many difficulties which have to be contended against when undertaking the treatment of morphinism, and the fruits of his experience contained in this volume should prove of value to those who are concerned in the management of such cases.

Physiology of the Special Senses. By M. GREENWOOD, jun., M.R.C.S. Eng. London: Edward Arnold. 1910. Pp. 239. Price 8*s.* 6*d.* net.

THIS work is intended to meet the wants of those who are desirous of taking up physiology as a branch of liberal education or with a view of presenting themselves for higher professional examinations, and also for students of psychology who may desire to obtain more information regarding the physiological side of the senses than is usually found in works dealing with psychology. There is no account of the anatomy and histology of the sense organs, save in the chapter on Comparative Physiology of Vision, where a few illustrations taken from Hesse's excellent illustrations of the visual organs in lower animals are given. There are also three rather crude diagrams of otolith organs in jelly-fish which do not harmonise with the other illustrations.

Considering the vast variety of impulses that reach the central nervous system from what are called the special senses, and how differently different physical agents act on bodily structure under varied conditions, the author begins his inquiry by asking whether there are any general formulæ or laws describing some relations between external stimuli and conscious reactions valid for all sense organs. The "formulæ" or "laws" that hold the field are those associated with the names of Johannes Müller (Berlin), E. H. Weber (Leipsic), and Th. Fechner (Leipsic). Müller's "law," the first in point both of time and importance, the "Law of Specific Energy," or "Law of Specific Sense Energy," is not happily phrased. Its import and importance, however, are well understood. There is no rigorous proof of its correctness, but the formula is of real scientific value. Weber's "law" introduces the question of the threshold or liminal value of stimuli. Fechner, accepting Weber's law as true, added a corollary, that the sensation varies as the logarithm of the stimulus. We agree with the author that "the formulation of a quantitative law is hardly justifiable"—i.e., as regards the attempt to measure sensations.

The cutaneous sensations are first dealt with (pp. 8–17). May we suggest that it might be well in the next edition to insert in brackets, so far as regards Weber's experiments on temperature, the equivalent value on the Centigrade scale for water at 29·5° Réaumur? Many readers are not likely to be familiar with the Réaumur scale. Gradually the terms "protopathic" and "epicritic sensibility" of Head and Rivers are finding their way into textbook terms based on Dr. H. Head's work, who voluntarily submitted to section of a nerve in his forearm in order to study in his own person the immediate and remote effects of section of a sensory nerve, as well as the phenomena of recovery of sensibility. With regard to pain the discussion is brief, and most of the problems which arise belong rather to psychology than to the physiology of the sense organs. Short chapters are devoted to taste and smell, and two to the sense of position and movement. In Exner's experiments on homing pigeons it might be well to explain what is meant by "galvanising" them (p. 49). Including a short historical introduction, the physiology of the ears occupies about 20 pages. In "Vision" we are introduced to the German term "Photirzellen." As was to be expected, the greater part is devoted to vision, nearly 130 pages—i.e., more than half of the whole work. There is a short chapter on Historical Theories of Vision, in which the author acknowledges his indebtedness to Beare's "Greek Theories of Elementary Cognition from Alcmæon to Aristotle." The scope of the treatment of the subject can but be indicated by mentioning the chief matters dealt with—e.g., retinal processes; electrical, phototropic, and chemical response; visual adaptation; peripheral vision; recurrent vision; total colour blindness; trichromatic and dichromatic vision; the Young-Helmholtz and Hering theories of colour vision; after-images; simultaneous contrast. The merits and demerits of the respective theories of colour vision are fully discussed. The last chapter is on "Space," including monocular and binocular vision, perception of depth, and stereoscopy. We do not find any reference to the newer classification of sense organs as "receptors."

The work will prove serviceable to those it is intended for. We think the author's advice is good that it would be well to read it in conjunction with Myer's "Text-book of Experimental Psychology," more especially as no attempt is made to bridge the gulf between the worlds of physiology and psychology, but appended to each chapter is a list of papers recommended for further study. We have noted some slips. We find "denteronopes" for "deuteranopes," and on p. 194, should not "white-red" be "white-black," and Zollner should be Zöllner.

LIBRARY TABLE.

Lessons on Elementary Hygiene and Sanitation, with Special Reference to the Tropics. By W. T. PROUT, C.M.G., M.B., C.M. Edin., late P.M.O., Sierra Leone. Second edition. Pp. xx.–159. London: J. and A. Churchill. Price 2*s.* 6*d.* net.—This little work is founded on a series of six lectures given by the author, who is so well known for his good administrative work in Sierra Leone. The author modestly describes it as an elementary textbook, but the reader will find in its pages a very complete guide in most matters relative to the preservation of health in the tropics. The design of the work is excellent. We first have the anatomy and physiology of the body described, and the indications to be deduced from the latter pointed out. The causes of disease are next entered upon, and here the writer gives us a very sufficient account of germs, their varieties, conditions of growth, how they get into the body, how they can be fought against outside the body, and lastly how Nature herself fights against them. Then we come to the diseases caused by the special germs, such as cholera, typhoid fever, dysentery, plague, yaws, and others, and here the methods to be employed in prophylaxis are clearly laid down. Malaria is the next subject considered. The history of the discovery of its cause is clearly given; the various forms of the parasite are detailed, the mosquito described and illustrated by some well-executed plates, and finally, the stages of the malarial parasite are portrayed. An excellent chapter on the prevention of malaria follows. Dr. Prout then proceeds to the subjects of sleeping sickness, of filaria, and of yellow fever; and here, perhaps, the author might have told us more fully of the experiments of the American Commission. The various intestinal parasites are described, as are also the guinea-worm, the jigger, the tumbu, and the

parasite causing craw-craw. A very important chapter is that on food. Here we find the points relative to the different kinds of food detailed and the amount of food necessary to be taken indicated. Then some of the diseases caused by food are alluded to, whilst the matters relative to cooking and the time for taking food in the tropics are not forgotten. This section concludes with the subject of beverages. An excellent method for making tea is given, and the rules for the drinking of alcohol could not be improved upon. Water-supply receives its full meed of notice: the characters of a good water, the sources of water and the indications to be gathered therefrom, the impurities of water and the diseases provoked by them, and lastly, the methods of purifying water—all are described. The remaining sections are connected with air and respiration and the subject of ventilation, and with the dwelling, its site, water-supply, sewage removal, and conservancy system. The author particularly points out the dangers inherent to cesspits and recommends the pail system. The final section embraces the matters connected with clothing, its materials, colour, and amount. The author has produced a book which every sojourner in the tropics should possess, for the lessons which it conveys are invaluable.

Medical Morbid Anatomy and Pathology. By HUGH THURSFIELD, M.D. Oxon., F.R.C.P. Lond., Senior Demonstrator of Medical Pathology, St. Bartholomew's Hospital, Assistant Physician to the Hospital for Sick Children, Great Ormond-street, and to the Metropolitan Hospital; and WILLIAM P. S. BRANSON, M.D. Camb., M.R.C.P. Lond., Junior Curator of the Museum, St. Bartholomew's Hospital, and Assistant Physician to the Royal Free Hospital. London: H. K. Lewis. 1909. Pp. 262. Price 6*s.* net.—This book is practically a small but convenient handbook to the student studying the morbid anatomy of medical diseases in a hospital museum, and the authors have given references to the specimens in the museum of St. Bartholomew's Hospital for the assistance of students of their own school. The descriptions of morbid conditions affecting the various systems and organs are, however, given didactically, so that they would be equally useful in any well-furnished museum. An introductory chapter is devoted to brief consideration of certain general pathological states and processes, including inflammation and the retrogressive tissue changes. Here we have brief accounts of the nomenclature and classification of tumours and of the life-history of the commoner parasitic worms. This chapter contains in condensed form a considerable amount of useful information, but it might have been extended with advantage. The remainder of the book is divided into chapters, each devoted to the diseases of an organ or of a system. The morbid processes affecting them are enumerated, and descriptions are given of their general characters and of their effects. These well written descriptions, though concise, are in the majority of cases adequate. The general arrangement and classification are good, and the authors have wisely not confined themselves to mere descriptions of specimens. To the student in the wards or working through the museum specimens after a course of systematic pathology this little book should be useful, and we can commend it for this purpose. The margins would allow room for the student to insert the numbers of specimens in the museum of his own school, and there are also some blank pages at the end of the book for notes.

Phono-Kardiogramme. Von Professor OTTO WEISS. Mit 41 Figuren im Text. Jena: Gustav Fischer. 1909. Pp. 37. Price M.1.50.—For the proper understanding of the time relations of the movements of the heart the relation between those movements and the moment of beginning of the two cardiac sounds is of the greatest importance. The author gives a succinct account of the various methods that have been used to record these sounds and their relations. In the subjective method of Martius the auscultator recorded, by means of a Marey's tambour, on a drum the tones when he heard them, at the same time recording a cardiogram. In the objective methods the vibrations produced by the sounds are transferred by various apparatus which are thrown into vibration and the vibrations themselves recorded. One of the best known of these methods is that of Hürthle, who used a microphone. Einthoven also used a microphone, but substituted the capillary electrometer for the rather sluggish electromagnet of Hürthle. Holowinski also used a microphone. Frank used a caoutchouc membrane which collected the vibrations, and on the membrane was placed a mirror which threw a beam on a photographic plate. The author substitutes a circular soap film, which he says in sensibility far exceeds the microphone. To this is attached a silvered glass thread. The whole apparatus he calls a "phonoscope." The author then proceeds to analyse the curves he has obtained both in health and disease, recording always at the same time either a cardiogram or the pulse at the carotid artery. He has also by his method been able to photograph the heart sounds of the fœtus in utero. It is obviously a method of extreme delicacy, and might well attract the attention of physiologists.

The Public Health Service Directory and Year-book, 1910. Compiled by the Editor of the *Medical Officer*. London: Hodgetts, Limited. Pp. 317. Price 6*s.* net.—This Directory will be of considerable service to public health officials and those who want immediate information in respect to the *personnel* of the various health departments of the country. The compilation gives the names, addresses, appointments, and qualifications of the medical officers and sanitary inspectors of all the health authorities in England, Scotland, and Wales. This list includes officials concerned in the medical inspection of school children. Another section gives particulars concerning the isolation hospitals, while space has been found for lists of public analysts, municipal dental officers, and veterinary officers. The directory has been compiled by Mr. George S. Elliston, the editor of the *Medical Officer*, who, in a frank preface, admits his knowledge that his lists of names and appointments cannot claim in many directions to be complete. In addition to the lists of names there are also articles defining the powers and duties of the medical officer of health, the veterinary officer of health, and the sanitary inspector, and there is a useful note on women in public health work. While most of the information in this directory can be obtained in other places we can conceive that there may be considerable convenience for many people in bringing it together under one cover.

Sehprobentafeln zur Bestimmung der Sehschärfe für die Ferne. By Dr. v. AMMON. Pp. 8 sheets and text. 1909. Munich: J. F. Lehmann's Verlag. Price M.4.—These new test types consist of letters, numerals, and hook-shaped figures built on the same principle as Snellen's test types. Like them, each figure subtends a visual angle of 5 minutes at the nodal point of the eye when it is placed at the stated distance, and the thickness of the individual strokes of the figures subtends a visual angle of one minute under the same conditions. The modifications from Snellen's types are so slight as to be scarcely sufficient reason for replacing the older and well-established types.

Register für Augenärzte. By Dr. med. GEORG HIRSCH. Leipsic: Verlag von Wilhelm Engelmann. 1909. Price M.7. —This is a case-index with columns for the record of year,

number of case, sex, and notes. The whole range of eye diseases is catalogued under appropriate headings, such space being devoted to each as the author thinks suitable. In this respect the book labours under the difficulty common to all indexes in book form—there is no elasticity. Thus one may consider that 86 pages out of 192 is an unduly liberal allowance for errors of refraction and accommodation, subjects which only those working at some particular point of interest in this domain are likely to wish to catalogue exhaustively at all. In our own experience the card-index system is superior to any other for such a purpose as that for which this book is primarily intended.

The City of London Year Book and Civic Directory for 1910. London: W. H. and L. Collingridge. Pp. 422. Price 5*s*.—At first sight this volume looks like the old familiar "City of London Directory," but closer inspection shows the compilation to be different in several particulars. The general directory of names and addresses of merchants and companies in the City has been omitted and the information in regard to the Corporation, County Council, City charities, committees, and Livery Companies has been retained and amplified. The old directory appeared annually for the past 39 years, and was largely valued for its special and exclusive information, all of which features have been retained under the new name and reduced price of 5*s*. This change will be welcomed by many. Moreover, the special information concerning the civic affairs of the City of London cannot but increase, so there is room for judicious expansion in the new book.

Reports and Analytical Records
FROM
THE LANCET LABORATORY.

"TABLOID" LODAL.
(BURROUGHS, WELLCOME, AND CO., SNOW HILL-BUILDINGS, LONDON, E.C.)

Lodal is regarded as a therapeutic advance on cotarnine, producing a tonic contraction in the pregnant and non-pregnant uterus; but it differs in exercising more effect on the heart, slowing and strengthening the beat and producing vaso-constricting action. Lodal is said to have the same effect on the higher centres, its action in this regard being more powerful than that of cotarnine. The principal value of lodal appears to be in cases of uterine hæmorrhage.

BULGARIAN SOURED-MILK CHOCOLATES.
(ROWNTREE AND CO., 1, GREAT TOWER-STREET, LONDON, E.C.)

Laboratory experiment proved the lactic-acid developing power of the contents of these chocolates. Milk sown with some of the interior portions of the chocolate developed lactic acid in a short time. From an initial acidity the acidity arose to three times as much in 24 hours. The chocolates are well prepared and there is not the slightest objectionable flavour about them.

ANALAX.
(R. DEMUTH, WORKS AND LABORATORIES, 68, SALUSBURY-ROAD, WEST KILBURN, LONDON, N.W.)

The claims for this aperient drug seem to be well grounded. The pharmacological basis of the palatable pastille, Analax, is phenolphthalein, which has been largely used as an aperient during recent years, some observers maintaining that it contains a group related to the active constituents of aloes. In the analax pastille the phenolphthalein is combined with a valerian group about which there are two points of therapeutic importance. Valerianic acid, in the first place, has a sedative effect, but this effect, owing to its rapid absorption, may pass off before the action of the aperient is begun. It is desirable, therefore, to obtain a sedative and aperient action simultaneously in the intestinal tract, and this is obtained by employing anavaleryl-acetyl-phenolphthalein. The analax pastille is a pleasant jujube which gives a mild but certain laxative effect. The drug acts without any suggestion of griping.

CAR-MA-ME PREPARATIONS.
(BASH AND CO., 35 AND 36, FOLEY-STREET, LONDON, W.)

We have received from the above firm a series of quite elegant preparations for the cleansing of the teeth and mouth. We have seen a list of the ingredients employed to make up the various preparations submitted, and each individual product is one that is well adapted for the purpose claimed for it. In addition to being germicidal they are pleasant to use. In the instances examined we found the description in regard to the ingredients present to be correct. The zinc chloride mouth wash deserves mention as an effective preparation for preserving the teeth and for improving the condition of the gums. The preparations in general may be confidently employed for producing a scientific cleansing of the teeth and mouth, and in spite of the presence of powerful germicidal agents they are agreeable to use in such employment.

WORMSER WINEMUST.
(AGENCY: GEO. OTTO HENNINGER, 11, GREAT JAMES-STREET, BEDFORD-ROW, LONDON, W.C.)

We have examined four varieties of this grape juice, which is stated to be expressed from grapes grown in the well-known vineyards in the district around Worms on the Rhine. They possessed an attractive flavour and were remarkably free from that mawkishness which marks some grape juices. The merest trace of alcohol was found, the quantity being quite negligible. The juice was in a good preserved state, although there was no evidence of chemical preservatives being present. The juice on boiling gave no coagulum. On analysis the Riesling specimen (white) gave the following results: extractives, 14·41 per cent.; mineral matter, 0·23 per cent.; grape sugar, 13·50 per cent.; and tartaric acid, 0·54 per cent. The specimen labelled Burgundy gave the following results: extractives, 14·65 per cent.; mineral matter, 0·20 per cent.; grape sugar, 13·70 per cent.; and tartaric acid, 0·56 per cent. The specimen labelled Liebfraumilch gave the following results: extractives, 18·58 per cent.; mineral matter, 0·33 per cent.; tartaric acid, 0·72 per cent.; and sugar, 16·65 per cent. The specimen called Portuguese gave: extractives, 18·50 per cent.; mineral matter, 0·25 per cent.; tartaric acid, 0·95 per cent.; and sugar, 16·65 per cent. It will be noticed that the last two are of a "fuller bodied" character than the previous juices.

PROTEID FOODS.
(THE WILTS UNITED DAIRIES CO., LIMITED, DEVIZES, WILTS.)

The feature of these food preparations is that they are for the most part enriched with milk proteid. According to our analysis, their general defect is the small proportion of fatty matters. In no instance did the fat exceed more than 5·3 per cent., except in the "protette" cocoa, which of course contains cocoa fat. We also note that the baby food is described as "free from starchy elements, which frequently cause stomach troubles," whereas we found the preparation to contain starch as well as sugar. The "albiron" food seems to have its claims based upon the presence of phosphates and of iron. We found a very small quantity of iron present but a considerable amount of phosphates, chiefly in the form of the insoluble calcium salt. The food was unattractive by reason of its peculiar smell. The proteids in these foods ranged from 23 to 31 per cent. and the carbohydrates from 45 to 58 per cent. The mineral matter throughout the series was high owing to the addition of phosphates.

THE LANCET.

LONDON: SATURDAY, APRIL 30, 1910.

Medical Internationalism.

WE gave an account recently of a meeting of the Bureau of the Permanent Commission of the International Medical Congresses. It is an excellent plan, that these great congresses should be directed and arranged by a permanent commission. In no other way can the administrative work of each congress be made sure of profiting by past experience. If there be no continuous authority, no traditional principles, no established procedure, all congresses become so much the harder to organise, and are in danger, more or less, of failure. Even with the help of a permanent commission innumerable difficulties attend the arrangement of a Congress of Nations and the three years of preparation for the International Medical Congress in London in 1913 will bring to the commissioners many problems of management. At the meeting held at The Hague, one of the commissioners presented a pamphlet by Dr. EIJKMAN on "Medical Internationalism." Dr. EIJKMAN is a fervent internationalist, and his pamphlet deserves careful study. It is published by the Bureau Préliminaire de la Fondation pour l'Internationalisme, a title not easily rendered into English, but it might be translated thus: First Steps toward taking the World as a Whole. The aim of this society is "the organisation of organisations," the drawing together and linking-up of all that each nation is doing for the official development of its own interests and well-being. For this purpose the society keeps records of the associations, unions, leagues, conferences, exhibitions, and congresses of every nation. Say that we wish to see at a glance what the whole world is doing to fight slavery, or drunkenness, or prostitution, or the sweating system, or the adulteration of food: the society has a list of the many societies all the world over that are thus fighting. Say that we wish to estimate what is being done by the world for the advancement of this or that art or science or charity: the society will tell us. By thus informing each nation of the doings of other nations the society hopes to bring about closer coöperation, better understanding, readier action, more intimate union. In brief, it is for the promotion of internationalism. And, of course, it has among its records the names and programmes of all international medical societies. The list of them is of great length, and many of them are held in honour everywhere. But, as Dr. EIJKMAN says, they are not all of equal importance; and he lays down this wise rule, that the organisation of organisations must not include those things which are not worth organising.

This word international, like other words of the highest nobility, is often abused. Half-a-dozen Germans play chess with half-a-dozen Englishmen, and call it an international tournament. Little societies of exceptional people, little *anti*-societies (who are not to be called enthusiasts, for that would debase another noble word), though at odds with the vast majority of mankind, call themselves international leagues, or even world's leagues, as if they represented the laws of nature. Indeed, it might be truly said that the titles which these societies give to themselves in their cradles are mostly in inverse proportion to their size, and many societies are written down as international which have little more than a local interest, and not much of that. Dr. EIJKMAN refers in the course of his pamphlet to some of these societies which are concerned—for better, for worse—with medicine, and even he seems to be impressed by the grandeur of their names. For instance, there is what he calls the Fédération Universelle de la Régénération Humaine. It sounds, in French, quite splendid; but its English name, the Malthusian League, removes the claim of romance. Again, there is the International League against Dust on the Roads; and the World's League of Opponents of Vivisection, which, as a witness told the Royal Commission on Vivisection in 1907, had 63 members; and the International Association for the Purification of Rivers, the Soil, and the Air. Altogether, there are so many international activities that little would seem to be left for merely national enterprise, if these societies lived up to their titles. All the same, the way of the world's life has been nationalism. It was all settled for us by the time that the earth was habitable for man. Seas and mountain-ranges kept the nations apart; profound differences of language, customs, and religion maintained them in a sort of natural isolation; and the legend of the tower of Babel has not yet lost its meaning. Out of it all has come a world full of differences, surprises, prejudices, racial antipathies, and wars. As time goes on these will all decrease in number or force, and we, who live in this day of vast facilities of transit, may be seeing the beginning of some system of fusion. But it must be remembered that if every phase of national thought could be internationalised, the discords would hardly be less than they are now. So soon as vaccination, for instance, was made an international affair, immediately antivaccination would also be made an international affair. At present each nation keeps its own discords to itself.

Of course, in matters of law and of arbitration the more internationalism we have the better, for in all those functions of the world's life which are controlled and regulated by law and order each nation is the concern of all nations. So great are the advantages which all nations obtain from international law that we ought to reckon it even higher than international medicine. But international medicine is the great handmaid of international law. Take, for example, the study of tuberculosis, or of plague, or of sleeping sickness. Certain facts have been made out, and are become the world's property, as to the ways in which these diseases are maintained and spread. But laws must be enforced and obeyed if these facts are to be used for the healing of the nations. And International Medical Congresses, the outward sign of medical internationalism, form special occasions for the distribution of these facts. It is a platitude that science does not recognise the differences that are between

the nations, but if the principles of science belong to all nations, the men of science do not. There is room for doubt whether men of science are not the better for restriction within the limits of nationality. They do the best work sometimes who work individually. Internationalism is the world's market for the output of individualism, the great exhibition of works that were each of them made by different men in different workshops. And it is certain that the world is enriched by this bringing together of their results, this wider publication of their teaching.

Bacteriæmia in Tuberculous and other Infections.

THE method of cultivation of the blood removed by puncture of a vein under rigid bacteriological precautions to discover micro-organisms, now generally known as the method of blood culture, has established itself as a valuable procedure in many infective diseases and has yielded results of notable value in regard to the diagnosis and even of the treatment of many general infections, especially in a group which has been classified as cryptogenetic septicæmia. Striking as these practical results have been, the contributions which this method has made to the scientific study of the pathology of bacterial infections have been no less remarkable. It has thrown considerable light upon the nature of the conditions to which the names of sapræmia, septicæmia, and pyæmia have been given. These terms were originally applied to the effects of invasion by the pus-producing cocci or their products. The advances of our knowledge have, however, led to the use of the term "septicæmia" to connote any condition in which the blood contains infective organisms, while the term "pyæmia," or the hybrid "septico-pyæmia," has come to indicate any condition of general or blood infection associated with secondary suppurative foci in the organs or tissues of the body. This extension of the original connotation of these terms has led to some confusion, and to obviate this, in the case of septicæmia, the somewhat ungainly terms "bacillæmia" or "bacteriæmia" have been proposed, or sometimes the name of the organism is appended, so that we may speak of a typhoid septicæmia or a gonococcal bacteriæmia. In the case of pyæmia, again, not only may a blood infection by means of streptococci and staphylococci lead to secondary suppurative foci or metastatic abscesses, but organisms like the pneumococcus, the gonococcus, the bacillus coli, the bacillus typhosus, proteus and pyocyaneus may do the same. The method of blood culture has, moreover, demonstrated that the dividing line between sapræmia or septic intoxication and septicæmia or bacteriæmia is difficult to establish clinically, and has further shown that not a few conditions originally regarded as sapræmias are, at any rate in a majority of cases, septicæmias: e.g., in enteric fever numerous observations by different workers have shown that in 75 or 80 per cent. at least of the cases typhoid bacilli can be demonstrated in the blood at a period before Widal's reaction can be obtained—i.e., before the protective mechanisms of the blood have been set into action sufficiently to reveal themselves. The whole subject is somewhat complicated by the fact, now well known, that the normal blood serum contains substances which destroy bacteria or inhibit their growth. This property, which was originally affirmed by TRAUBE so long ago as 1874, was lost sight of until the important researches of NUTTALL in 1888, followed by those of HANKIN and BUCHNER, established it on a sure foundation of ascertained experimental facts. Apart from this protective action of the serum or plasma, bacteria injected into the blood stream are rapidly removed from it by the activity of the endothelium of the blood-vessels and by the phagocytic action of the white blood corpuscles, so that, unless the organisms have been injected in overwhelming numbers, it may be difficult or even impossible to demonstrate their presence in the blood shortly afterwards either in films or by culture, although if a general infection results they may be found at a later period, when the protective reactions have broken down or become insufficient.

In view of the complexity of processes involved in infection and in immunity reactions, it is not surprising that there are many gaps in our knowledge of the precise characters of many specific infections. Some recent observations on human tuberculosis and experimental inoculation of animals by the tubercle bacillus tend to show that our views on the relation of the bacilli to the blood stream in these conditions may require modification. It has generally been supposed that in ordinary cases of localised tuberculosis few bacilli reached the blood stream, and that these were rapidly removed or destroyed; so that only in cases of general miliary tuberculosis and in the condition described as "typhobacillose" by LANDOUZY[1] were bacilli present in considerable numbers in the blood stream. However, Dr. L. COBBETT[2] demonstrated the presence of tubercle bacilli practically all over the body in calves within three days of the subcutaneous injection of 50 milligrammes of a non-virulent culture. He explains this as due to a passive escape and not as an active invasion, but the dissemination must have been effected through the agency of the blood stream. Dr. A. S. GRIFFITH and Dr. F. GRIFFITH[3] showed that tubercle bacilli were distributed all over the body of animals within 24 hours after subcutaneous inoculation, and they were able to inoculate guinea-pigs successfully with tuberculosis by means of the blood from these animals. In February, 1909, Dr. R. C. ROSENBERGER[4] published the results of his observations, in which he claimed that he had found tubercle bacilli in the blood in every one of 125 patients examined suffering from tuberculosis. In a second paper[5] he has extended his cases to a total of 300, and states that tubercle bacilli may exist in the blood of persons apparently healthy. These somewhat startling statements have not passed unchallenged, and while some observers report finding tubercle bacilli in the blood of tuberculous patients and in experimental tuberculosis in animals, others have obtained negative results. In these circumstances the examination of the technique employed by different observers becomes a matter of importance. The

whole question is reviewed in two interesting papers, one by Dr. JOHN F. ANDERSON,[6] the other by Dr. WILBUR A. SAWYER.[7] Dr. ANDERSON refers to the important paper of BERGERON[8] in 1904, in which a critical summary of previous work is included, and discusses the technique employed by Dr. ROSENBERGER, which was to draw about 5 cubic centimetres of blood from a vein in the arm and mix it with an equal quantity of 2 per cent. sodium citrate in normal saline solution. The mixture, after being well shaken, was placed in a refrigerator for 24 hours, when smears were made from the sediment and stained for tubercle bacilli. Dr. ANDERSON made a careful study of the blood in 48 cases of human tuberculosis and in 13 guinea-pigs and 8 rabbits experimentally infected. He examined films and cultures and investigated the results of inoculation of the blood into guinea-pigs. Of the 48 cases of human tuberculosis, 47 were examples of pulmonary tuberculosis with bacilli in the sputum, the remaining case being one of joint tuberculosis. In not one of them were tubercle bacilli demonstrated by examination of films, cultures, or animal inoculations. In one instance the films showed an organism having the morphological appearance and staining reactions of the tubercle bacillus, but it did not grow in cultures or infect guinea-pigs when inoculated. It is suggested that as the patient was a stableman, and the bacilli were not found in the blood immediately after withdrawal but only in the sediment after it had remained in an ice-chest all night, they may have been due to contamination with an acid-fast hay or grass bacillus. The results obtained in the case of the eight rabbits were interesting. In seven of them tubercle bacilli were found in the blood either by culture or guinea-pig inoculation or by both means. In spite of this, on careful observation by several observers of stained films made from the blood, in not a single instance could the bacilli be found. Of the 13 guinea-pigs, only one showed the presence of tubercle bacilli in its blood as tested by inoculation. It appears, therefore, that whereas tubercle bacilli can frequently be found in the blood of tuberculous rabbits, it is rare to find them in the blood of tuberculous human beings or of guinea-pigs in sufficient numbers to be demonstrable. The fact that Dr. ANDERSON could not demonstrate the bacilli in films from blood which was proved by culture and inoculation to contain bacilli tends to throw doubt upon Dr. ROSENBERGER'S observations. Dr. SAWYER was also unable to confirm them in the human subject, and therefore made a systematic investigation of the blood of tuberculous cattle, working in conjunction with Dr. C. M. HARING. He describes their technique, which was modelled on that of Dr. ROSENBERGER. Special precautions were taken to avoid contamination with acid-fast bacilli, even the distilled water, which, as has been shown by Dr. W. V. BREM,[9] may contain them, being carefully examined in order to ensure that it was free from such contamination. In 167 preparations made from the blood of 39 bleedings from 21 tuberculous cattle no tubercle bacilli were found. In one of the animals, after tubercle bacilli had been directly introduced into the arterial blood stream, they were found in the blood 25 minutes later, but not after one and a half hours, thus showing that the bacilli are rapidly removed from the circulation. Certain observations seemed to indicate that the capillaries of the lungs are more effective in arresting or removing bacilli than those of the peripheral circulation, which may be an explanation of the frequency of pulmonary implication in the tuberculous process when bacilli have entered at distant parts.

Although bacteria have been demonstrated in blood films made from the sediment after standing or centrifugalisation, the above quoted observations show that reliance cannot be placed upon them unless they are confirmed by culture or inoculation from the blood directly. The possibilities of contamination are so numerous that the most rigid precautions must be taken. Moreover, in order to render the results of blood culture of any value a sufficient quantity of blood must be withdrawn—at least 5 cubic centimetres, and if possible 10 or even 20. This should be divided between as many different culture media as possible and the inoculation of the media should be carried out directly after withdrawal, or with the least possible loss of time, in order that the bactericidal effects of the blood serum may be avoided. There can be little doubt that even in regard to the tubercle bacillus and its dissemination there is much yet to learn, and that systematic investigations such as those of Dr. ANDERSON and Dr. SAWYER afford valuable information. It is to be hoped that future workers will, as these observers have done, give full details of their technique and that by this means discrepancies may be avoided and the questions at issue satisfactorily settled.

The Constitution of the Prison Commission.

A DISCUSSION took place in the House of Commons at the end of last week over the substitution, as a Prison Commissioner, of Mr. M. L. WALLER, until recently Lord GLADSTONE'S private secretary, for Dr. H. B. DONKIN, the medical member of the Commission, who has retired under the age limit. That this discussion should have been necessary is at once a subject for congratulation and for regret; for congratulation in that it showed what growing importance is being attached by the public to the opinions of trained medical men in the Civil Service, for regret in that it brings into prominence what seems to be a rooted antipathy on the part of the clerical staff of a great bureau to the admission of men of science into the administrative offices even at a period in our national existence when everything is proving the importance of scientific methods in government. It might indeed be inferred that to add a scientific training to an already extensive lay education is regarded in the Civil Service as a depreciation rather than as an appreciation in value—an inference which receives support from the relatively small salaries which are granted to medical men in the public services. As an actual fact, a combination of medical and lay training is the one above all others which fits a man for any administrative office into which considerations for the physical and mental well-being

of the community enter; and the fact that Dr. DONKIN, a learned physician, has been replaced on the Prison Commission by a gentleman possessing only, if excellent, secretarial credentials is exceptionally unfortunate.

When some 12 years ago, as was well brought out by Sir HENRY CRAIK in the debate on the subject in the House of Commons, the Prisons Bill was introduced by Sir MATTHEW WHITE RIDLEY, at that time Home Secretary, several members of the present Government were clear in their insistence that one of the three Prison Commissioners must be a qualified medical man; and Sir MATTHEW WHITE RIDLEY, promising to strengthen the medical element, added that no doubt future Home Secretaries would adhere to the same principle. Mr. BALFOUR at the same time promised to have an official minute entered in the Home Office's archives on this matter. Dr. DONKIN was accordingly appointed by Sir MATTHEW WHITE RIDLEY; but as soon as he retires a young layman is appointed to fill his place by a Government presumably representing the very persons who so strongly advocated the principle of always having a medical man on the Commission. There is no political significance in the appointment, but it is difficult to regard the occurrence, as Sir HENRY CRAIK pointed out, as other than a reflection upon the sincerity of what is said in the House of Commons. With Mr. ROOSEVELT'S eloquent address at the Sorbonne fresh in our memory, we must not admit "that political morality differs from private morality, or that a promise made on a platform is different from a promise made in everyday life." Now the promise that the Prison Commission should be strengthened medically was made from a more reputable place than a platform—namely, from the front bench in the House of Commons—and it is sad that it should be broken in a cynical manner and as a matter of convenience. An endeavour was made to justify Mr. WALLER'S appointment on the ground that the whole-time services of Dr. DONKIN were being retained for five years at a salary of £200 per annum. Although we are glad to know that Dr. DONKIN will receive this augmentation of his pension until he is 70 years old, we cannot regard the arrangement as a substitution for a medical Commissioner, or as a good method of dealing with the situation. The rule which holds in the Civil Service that a man must retire at 65 is sound. An arrangement by which services are retained until 70 is unsound, if only because the conditions of service are violated; but, this apart, as Mr. BALFOUR observed, "the whole point of the decision taken in 1898 was that a man who gave medical advice ought to be one of the persons responsible for seeing it carried out." Has Dr. DONKIN now a vote on the Board?

Unless some procedure can be arrived at by means of which there may be four Commissioners, one medical, in place of three, all lay, the injustice which has been perpetrated is likely to obtain for another five years, or until Dr. DONKIN feels that he can no longer devote his whole-time services to the Home Office for £200 a year. It is disappointing to find Mr. MASTERMAN, whose writings and speeches reach such a high ethical level, by way of apologising for this unfortunate business, for it is quite clear, as Sir WILLIAM COLLINS pointed out, that the need for a medical member on the Prison Commission is greater now than it was in 1898. The passing of the Inebriates Act, for example, has added to the duties of the bureau. It is our opinion that in justice to the progress of prison reform this matter cannot be left where it is, and, unsatisfactory as it would prove economically, probably the best compromise, if no other duties can be found for the promoted private secretary, is to appoint a fourth—and medical—Commissioner. It is unfortunate that this episode should have occurred at a time when Royal Commissions and public opinion are alike emphasising the importance of engaging the services of specially qualified men to deal with situations where a medical training is essential; and it would serve to re-establish public confidence if the Home Office would at once rectify this administrative slip. It will be useful to assure the public that in future posts practically created for men with scientific attainments shall not be bestowed upon laymen. Mr. CHURCHILL has made an official explanation, but we hope that the subject will not be allowed to lapse.

Annotations.

"Ne quid nimis."

PHARMACOPŒIAS.

A COMPLEX civilisation necessitates the division of labour and the differentiation of functions, and this axiom applies to the practice of medicine as to all other forms of human activity. Time was when the physician culled his own simples and prepared with his own hands the remedies which his patients required; but in these latter days such work is assigned to pharmacists who are specially trained to perform it, and whose functions are often again subdivided, different individuals performing the operations of galenic and extemporaneous pharmacy. That the complementary labours of physicians and pharmacists may be efficiently performed it is essential that they should work in complete accord. There must be no secrecy between them; the physician must give explicit instructions as to what he requires, and the pharmacist must be ready to explain in detail how he fulfils his trust. In a word, they must speak a common language if the dangers of empiricism on the one hand and charlatanism on the other are to be avoided. These considerations have led to the compilation and publication of pharmacopœias, which are essentially recipe books, specifying in detail the variety, quality, and strength of each medicament which they name, and giving formulæ, processes, and methods of assay in order to ensure uniformity in compound preparations. When an article included in a pharmacopœia is prescribed something which answers the requirements of that book should be supplied, but it is somewhat doubtful how far this moral obligation can be enforced by legal process. In order to elucidate this question we have asked a legal contributor, who has made a special study of it, to state his opinion for the benefit of our readers, and this he has done in an exhaustive article, which will be found on page 1220 of the present issue. It will be noted that special stress is laid upon the importance of discriminating between drugs as such—that is to say, when used in medicine—and the same substances when used for manufacturing, commercial, or domestic purposes. We trust that this important point will receive the earnest attention of the committee now engaged in drafting a new edition of the British Pharmacopœia, and would commend to their notice the following pregnant words which are to be found in the preface to the Pharmacopœia of the United States of America: "Inasmuch as there has existed in the past on the part of

the public a misconception of the purposes of a pharmacopœia, and penalties have been imposed upon those who have sold substances bearing pharmacopœial names which were to be used in the arts, for manufacturing and other purposes, and not as medicines, it has become necessary to make the following declaration—'The standards of purity and strength prescribed in the text of this Pharmacopœia are intended to apply to substances which are used solely for medicinal purposes and when professedly bought, sold, or dispensed as such.'"

THE PATHOLOGY OF MUMMIES.

IN the manner of children with toys the ancient Egyptians went through a process of make-believe with their dead. Well acquainted as they were with the rapid putrefactive processes of a hot climate, they thought to frustrate these by embalming corpses so as to resist decay and to retain, perhaps for ever, some semblance of their habit as they lived. Whatever its later developments, the pathetic original theory evidently was that the dead only slept, and if their bodies could be kept intact they would at some time or other awake and resume the ordinary business of life. Hence, of course, the fact that the dead were often buried in mortuary chambers with furniture and utensils about them. It has been left to Europeans, some 8000 years and more after the date of the eighteenth to twentieth dynasties, to make the melancholy discovery that the Egyptians buried many things with those whom they loved, for which the latter had no sort of use in a second life. Had they known, for instance, what they were about, they would certainly not have been at pains to ensure the perpetuation of diseases in the mummies under their care. Still more, they would have refused a factitious eternity to parasitic life or bacteria. One is almost glad that the old pious Egyptians are not able to see the unrolling of their friends, for their feelings might be hurt by our discovery of pathological conditions probably never suspected or understood by them. Writing in the *Cairo Scientific Journal* for January, 1910, Dr. M. Armand Ruffer has given an interesting account of his examination of a number of mummies of the period of the eighteenth, nineteenth, and twentieth dynasties, now in the Hearst collection in the Museum of the School of Medicine at Cairo. From this microscopic examination it would appear that the ancient Egyptians exhibited a variety of grave pathological phenomena. Arterial disease was of "frequent occurrence, and, indeed, temporal arteries of mummies in various museums are as tortuous as they are at the present day, even in people who died when comparatively young." Lung disease was common. "The lungs of one mummy (twentieth dynasty) present all the signs of diffuse anthracosis," being choked with soot, as though in life they had been in smoke-laden air. "Numerous micrococci are packed in an alveolus" of another set of lungs, and Dr. Ruffer does not hesitate to diagnose pneumonia, "which had advanced to the stage of hepatisation." In the tissues of the liver and the blood-vessels of the same mummy large numbers of bacilli were also found. "These bacilli stain well with hæmatoxylin, methylene blue, fuchsin, but not with Gram's method. ..... It is clear that microorganisms retain their characters unaltered in mummified tissue." These particular ones were ovoid in form and "about the size of plague bacilli though plumper." In other mummies renal lesions were found, which took the form, in one case, of multiple abscesses, full again of bacilli resembling bacillus coli. All these microorganisms were dead and incapable of doing harm. In examining a renal calculus of Dynasty II. Mr. Shattock, the pathological curator of the Museum of the Royal College of Surgeons, found in a closed central cavity a mass of mould conidia in so good a state of microscopic preservation that he unsuccessfully attempted to raise a growth from them—they were dead. Were the bacilli of mummies capable of spreading disease among the living, who shall say what results might not follow?

HEALTH PROGRESS AND ADMINISTRATION IN THE WEST INDIES.

IN the spring of last year Sir Rubert Boyce, F.R.S., at the request of the Secretary of State for the Colonies, visited Barbados to investigate the circumstances associated with a local outbreak of yellow fever, and subsequently by official request he extended his visit to a number of other West Indian colonies to advise them generally on sanitary matters. An extremely interesting narration of his experiences has now been published in book form,[1] with a view of affording information not only to the medical profession but also to the public, including the tourist, the man of business, or indeed anyone who desires to visit temporarily, or reside permanently in, any of these beautiful West Indian islands. As regards Barbados, it possesses great natural advantages; its climate is dry and bracing, and the island is continually swept by refreshing breezes from the Atlantic Ocean. The soil is coral limestone, absorbent as a sponge. Under these conditions it is obvious that malaria-conveying mosquitoes cannot find favourable breeding-places, and, as a matter of fact, there is no indigenous malaria, Barbados being one of those parts of the tropical world which stand out unique in this respect. On the other hand, the stegomyia calopus is the common house mosquito of the colony. Some years ago the conditions which afforded opportunities for the breeding of this insect were almost entirely destroyed, more especially at Bridgetown, the chief seaport and capital of the island, by the introduction of a piped water-supply. This resulted in the removal of the barrels in which formerly water had been stored in close proximity to the dwellings, and in which the stegomyiæ previously had bred freely. In the past, yellow fever had often been epidemic in Bridgetown and other parts of the colony; but, as has been indicated above, the disappearance of this disease coincided with the introduction of a piped water-supply into the chief town. The epidemic investigated by Sir Rubert Boyce began in 1907, its origin having been ascribed to imported infection probably from the Amazon, Trinidad, or Martinique. The malady, it is now known, had existed unrecognised for some months in Barbados. No cases had occurred for a period of 26 years prior to 1907, so that the local medical practitioners were not familiar with the clinical characters of the disease. A large proportion of the cases occurred among the native black population, a generation of susceptible subjects having arisen since the occurrence of the last outbreak in 1881. It is asserted that if there had been proper medical administration in Barbados yellow fever would never have gained a footing in the colony in 1907. The sanitary organisation is said by Sir Rubert Boyce to be out of date; it is, he says, "as ancient and as picturesque as the characteristic sugar-cane crushing windmills dotted all over the island—eminently respectable but shabby, and not in conformity with the present age, nor calculated to yield the maximum return." There is no registration of the causes of death and there are no proper district medical officers of health, nor is there a chief medical officer of health to advise the executive and keep them informed of the health conditions of the colony. No regular reports are submitted and no information as to the sanitary circumstances of the island is

[1] Health Progress and Administration in the West Indies. By Sir Rubert Boyce, M.B., F.R.S. With 47 illustrations and 1 map. London: John Murray. 1910. Pp. 328. Price 10*s*. 6*d*. net.

forthcoming unless specially asked for. In most parishes the parochial medical officer appointed under the Poor Relief Act is the adviser of the vestry on health questions, but his only responsibility is to make a quarterly report. No definite or systematic inspections or inquiries into sanitary conditions are required of him, and his reports are often perfunctory. As these appointments for medical relief purposes are in the hands of the vestry, which can relieve the officer of his duties at six months' notice, he is not in a position to comment freely on insanitary conditions coming under his observation, as by doing so he is likely to offend the susceptibilities of his employers, on whose goodwill his tenure of office depends. We may here remind our readers that something closely resembling this is not unknown in a number of districts in England and Wales, where the part-time medical officer of health has frequently to submit to annual reappointment, and if he offend a majority of his council by a display of zeal he is liable, as a reward, to be superseded in his appointment. Summing up the state of sanitary administration in Barbados Sir Rubert Boyce describes it as "barbaric and primitive" and standing in urgent need of improvement. Accordingly, he recommends the Government to introduce a Bill without delay for the registration of deaths and causes of mortality, and for the establishment of a chief medical officer of health for the island with local medical officers of health under him for each district. These reforms should prove neither difficult nor costly; they would, if properly carried out, lift the colony into the first rank, and might make it simultaneously the ideal recuperating ground for the tired-out and sick ones of Europe and the United States. In this connexion we quote Sir Rubert Boyce's expression of his impressions of the health-restoring qualities of Barbados: "I shall never forget," he says, "the feeling of absolute repose, coupled with the stimulating and invigorating effect of the climate and scenery, which I experienced at all hours of the day, whether in the early morning, in the noonday sun, or in the late eventide; no matter what the hour, everything in life appeared sweet."

HARLEY STREET AND MEDICAL LOCALITIES.

IN the "Strange Case of Dr. Jekyll and Mr. Hyde," Cavendish-square is referred to by Robert Louis Stevenson as "that citadel of medicine," but the vogue of Harley-street, Wimpole-street, and the famous square is not, indeed, very ancient. The physicians and surgeons of the earlier part of the nineteenth century had mostly not moved so far west. They lived in Bedford- and Russell-square, or, in the case of several famous surgeons, close to the College in Lincoln's Inn-fields, while Finsbury-square had not by this time lost its attractions. The great medical men of the eighteenth century had no particular quarter; they lived scattered in fashionable parts of town. Radcliffe lived in Bow-street, and John Hunter in Leicester-square, not far from his brother William. Mead prided himself upon his spacious library, 60 feet long, in Great Ormond-street, where he entertained Dr. Freind from Albemarle-street and the literary physician Arbuthnot, from Cork-street, Burlington-gardens. This was in the mid-eighteenth century, at which period the City still flourished as the home of wealthy citizens, among whom were many resident physicians of repute. We get an early glimpse of Harley-street in 1780, when the notorious Lord George Gordon lived there on the confines of the open country to the north. To a sensible but less obvious extent practitioners in medicine and surgery have followed their Colleges as well as their patients. The first College of Physicians in London was in a certain sense the house of Linacre in Knightrider-street. Afterwards the physicians established themselves near Newgate, where, on moving to Pall Mall East, they were succeeded by the butchers of Newgate Market. The English surgeons, after being housed at Barber Surgeons' Hall in the heart of the City, came west, also to the neighbourhood of the great prison. The physicians established themselves in their present College in 1825; the surgeons were finally located in their first College in Lincoln's Inn-fields in 1813. Medicine and surgery having now established themselves, not in a corporate capacity but so far as the heads of the profession are concerned, in Harley-street and its neighbourhood, the Royal Society of Medicine is about to build its new home on the borders of that medical quarter of London. The student of London fashion may wonder whether, in a very few years, an exodus of the general well-to-do residents may not take place from Marylebone in the direction of Kensington or Hampstead, for there is certainly no finality in these questions of habitat. For ages it has been customary for the west ends of towns to be the resort of leisure, wealth, and fashion. But there will not be the necessity nowadays that prevailed in the eighteenth and most of the nineteenth century to establish central buildings where medical men may congregate, nor quite the same inducement for medical men to follow a peregrinating public. Enormously increased facilities of transit are rapidly making all parts of the metropolis accessible to everyone.

THE PATHOLOGY OF INFECTIOUS JAUNDICE.

AT a meeting of the Société Médicale des Hôpitaux of Paris on March 4th, M. P. Abrami, M. Ch. Richet fils, and M. R. Monod made an important communication on the pathology of jaundice. M. Abrami, in collaboration with M. Lemierre, has recently put forward the view that infectious jaundice (*ictère infectieux*) is usually the result, not of ascending infection from the intestine, but of descending infection from the blood. Of this the jaundice which sometimes occurs in connexion with typhoid fever is an example. The systematic examination of the blood in cases of infectious jaundice by Widal and other French observers has confirmed the view stated. The following case is an example. A woman, aged 36 years, was admitted into hospital with the diagnosis of scarlet fever. Eight days previously she was confined at term. In the last three days she presented signs of puerperal fever, and on the previous day generalised erythema and jaundice appeared. On admission the temperature was 105·6° F., the pulse was 160, the face was sunken, the eyes were surrounded by dark circles, and the lips were dusky. The patient was fully conscious and complained principally of hiccough and difficulty of breathing. There were manifest signs of general peritonitis; the abdomen was tympanitic and very tender in the hypogastric and iliac regions. The respiration was short and rapid and of the superior costal type; the diaphragm seemed to be immoveable. The erythema had all the characters of the puerperal scarlatiniform rash; it affected the whole body excepting the face and was most marked on the neck, abdomen, and thighs. There was neither angina nor scarlatinal stomatitis. The jaundice was well marked; the face and conjunctivæ were of a sulphur-yellow colour. The fæces were decolourised and the urine was dark-coloured and contained bilirubin in abundance. The liver extended three finger-breadths below the ribs and the spleen was enlarged. Death occurred in the evening. A culture made from the blood during life yielded in 24 hours a pure growth of streptococci, which on inoculation into a rabbit produced typical erysipelas. At the necropsy the uterus was found to be of the size of a fist; it contained neither clots nor placental remains, but a little opaque inodorous serous fluid. Its internal surface was of a violaceous-red colour and its walls

were flabby and œdematous. There was ulcerative endometritis. The fluid in the uterus contained streptococci in abundance and they were also present in sections of all the coats of the organ; some of the venules were thrombosed. There was no pelvic peritonitis, but there was a little opaque serous fluid in the pelvic cavity. The liver was large and a little softened. On section it showed greenish and violaceous colours. The gall-bladder contained transparent fluid devoid of bile-pigment but giving Pettenkofer's reaction. The fluid contained numerous epithelial cells, a few polynuclear leucocytes, and streptococci. There was no obstruction of the bile-duct or biliary passages, and histological examination of the intra-hepatic ducts showed no angiocholitis. Fragments of liver, the surface of which was cauterised, yielded a culture of streptococci. Histological examination of the liver was unsatisfactory in consequence of decomposition. This case is a further example of the thesis of M. Abrami and M. Lemierre that infectious jaundice is usually only a localisation in the liver of a general bacteriæmia. It is generally supposed that such cases are examples of angiocholitis, which, by causing swelling of the biliary passages, produces retention. Angiocholitis, no doubt, occurs in some cases of infectious jaundice, but such cases as the one now recorded suggest the question whether when present it is the cause of the jaundice or only an accessory condition. Further, marked angiocholitis has been found in cases without the slightest trace of jaundice. It follows that infectious jaundice is due to parenchymatous changes in the liver itself—in other words, to hepatitis.

COLD WEATHER AND PLANT LIFE.

THE present snap of cold weather in regard to its effect upon the life-processes of the plant recall the results of some interesting experiments in which plants were submitted to artificial cold and to the action of certain volatile fluids. It is well known that the potato develops a sweet flavour after it has been exposed to frost, and there seems to be little doubt that this is due to the formation and accumulation of sugar by the enzyme. Under favourable conditions of temperature there is no accumulation of sugar, because the oxidation or respiratory process proceeds unhindered and sugar disappears. Cold does not stop the enzyme working, but it arrests the respiratory process, which thus fails to destroy the sugar, and so it accumulates in the tuber and gives it the well-known sweet taste of a frost-bitten potato. Further observations have shown that cold precipitates an interaction between such glucosides as are present in the leaves of certain plants. When, for example, the leaves of crucifers are strongly chilled or exposed to the vapour of chloroform they soon give evidence of mustard oil being present. Similarly, the leaves of gaultheria produce methyl salicylate, the constituent of winter-green oil. Then in the case of those plants which produce hydrocyanic acid, the so-called cyanogenetic plants, the leaves on chilling evolve prussic acid. For some reason not yet clear it would appear, therefore, that the chloroformisation or etherisation, or chilling of plant leaves sets up an interaction between what glucosides and ferments are present, resulting in a premature formation of products which would be steadily and continuously evolved under normal conditions of temperature. It is hardly surprising, in view of these results, that when the even tenour of the spring or summer season is disturbed by the intrusion of a period of very cold and severe weather a profound influence one way or another is brought to bear upon vegetable life. It is difficult to conclude that unseasonable weather is without similar disturbances on the human mechanism. Apart from temperature, the question of moisture alone has a greater bearing upon the well-being of individuals than hitherto has been conceded to it when we consider the important part which moisture plays in the great vital processes. The study of moisture in air as a factor in health is still in its infancy, and it is a question whether, after all, the great fluctuations in the degree of humidity of the air to which we in the English climate are exposed are not more directly responsible for unsteady health than are the variations of temperature.

SUTURE OF THE RECURRENT LARYNGEAL NERVE.

IN the *Boston Medical and Surgical Journal* of Feb. 24th Dr. J. S. Horsley has reported what appears to be the only case on record of suture of the recurrent laryngeal nerve in man. A considerable amount of experimental work has been done, chiefly by those interested in veterinary surgery, in which the left recurrent laryngeal nerve was divided and implanted higher in the vagus. Most of these experiments were successful in restoring the function of the laryngeal muscles supplied by the nerve. In Dr. Horsley's case the left recurrent was injured by a bullet and all the laryngeal muscles supplied by it were paralysed. Three months after the injury an incision was made along the anterior border of the sterno-cleido-mastoid muscle and the injured nerve was easily found in the groove between the œsophagus and trachea. The injured portion was excised, excepting a small filament consisting of the posterior part of the nerve sheath. The ends of the nerve were brought together with a single suture of No. 0 chromic catgut and a fine curved needle. Some muscle tissue was drawn over the sutured nerve. The wound healed by first intention and the patient left the hospital nine days after the operation with no improvement in voice or breathing. Subsequently gradual improvement occurred. About two months after operation a laryngologist found improvement in the muscles supplied by the nerve; 15 months after the operation recovery was complete.

THE TREATMENT OF MENINGOCOCCUS CARRIERS.

THE part played by the healthy carrier of certain infective organisms in disseminating the diseases produced by them is now generally recognised, and measures for the diagnosis and quarantine of carriers have been frequently discussed, notably in regard to carriers of the typhoid and paratyphoid organisms, the diphtheria bacillus, and the meningococcus. We published in THE LANCET of April 16th an annotation dealing with the measures employed to deal with the carriers of the meningococcus in Belgium. An interesting paper by Dr. Hans Bethge of Gelsenkirchen appears in the *Deutsche Medizinische Wochenschrift*, No. 2, 1910, describing the means employed to deal with the carriers in an epidemic of meningococcal meningitis at the Catholic Orphan Asylum in that town. Nine cases of the disease occurred, 8 of the patients being girls, one a boy. They were treated by intraspinal injections of Kolle-Wassermann serum and all recovered, except one child which died some months later from pulmonary tuberculosis. All the inmates of the institution were examined for the presence of meningococci in the naso-pharynx and 60 carriers were found, distributed as follows: 5 nurses, 2 workmen, 32 girls, and 21 boys. Of these, 57 were isolated and systematic endeavours were made to get rid of the meningococcus by various means. In order to judge better of the relative value of the different measures employed, the 57 carriers investigated were divided into six groups, and in all except one of these groups the naso-pharynx was first irrigated by means of 1 per cent. sodium chloride solution run in from

a pressure height of one metre. The first group was treated with a spray of pyocyanase, the second with an irrigation of 3 per cent. perhydrol, the third with a spray of Kolle-Wassermann serum, the fourth with an irrigation of protargol in 1·5 per cent. solution, the fifth by simple washing out with salt solution, while the sixth group received no treatment of any kind. The irrigation with saline and the other forms of treatment were carried out twice daily. The results demonstrated that the meningococcus persisted longer in the cases without treatment than in the others. The spraying with serum gave only a slight result; pyocyanase, perhydrol, and protargol acted fairly satisfactorily, the perhydrol giving the most rapid effect, since the meningococci disappeared on an average after 8·6 days of treatment, whereas nine days were required with protargol and 12·7 with pyocyanase.

AMERICAN MORTALITY STATISTICS.

IN view of the near approach of another decennial British census, and of the preparations now proceeding for that event, the experience of other countries enforcing periodical counting of their inhabitants becomes for us especially interesting at the present time. The latest census returns of the United States of America have been utilised by Mr. Edward B. Phelps of New York for the preparation of an elaborate analysis[1] of American mortality statistics, the necessary data having been derived from the special reports of the Census Bureau at Washington. Until quite recently the only trustworthy American vital statistics were those compiled annually for "a mere handful of States in the East." The vital statistics of the decennial censuses are judged by the author to be practically worthless—comparisons of figures for single years a decade apart being for many reasons untrustworthy. Owing to loose legislation respecting birth and death registration, the imperfection of death certificates, and the frequent changes in the *personnel* of registration bureaus, no useful comparison has until recent years been possible of the records of even the group of districts within the registration area. Even now the data required for accurately computing the death-rates of the United States as a whole are lacking. Nevertheless, inasmuch as the existing registration area includes more than half of the population of the United States, Mr. Phelps is satisfied that the foundations for computing the nation's annual death-rates have now been fairly laid. In the present pamphlet the annual mortality records of the Census Bureau are presented in detail for each consecutive year from 1900 to 1908, and as far as the author is aware this detailed information has not previously been published, although comparisons have occasionally been made for shorter periods of time. Before entering on his detailed analysis, the author is careful to make allowance for certain factors that disturb his calculations. For example, (1) the constantly changing character of the population in the registration areas, and (2) the circumstance that less than 7 per cent. of the total deaths were those of coloured persons; from which it appears that the Southern States, with a large proportion of coloured races, are for the most part excluded from the benefits of registration. Mr. Phelps includes a table in which the death-rates are compared for each of the nine years above specified, and in addition the average rates are shown for the last four as contrasted with the first five years of that period. The mortality rates are given not only for all causes but for 16 groups of causes, in the urban and in the rural parts of the registration area. From this table it appears that in the last four years, as compared with the first five of the nine-year period ended with 1908, the general death-rate fell from 16·6 to 16·0 per 1000. In a population of rather more than 40,000,000 this fall means a saving of nearly 90,000 lives in the four years as compared with the numbers that would have been lost had the average general death-rate of the previous quinquennium been maintained throughout the later period. The bulk of this life-saving occurred in the chief cities of the registration area, where the decrease of the death-rate was equal to 36 per 100,000 of the population, whilst the decrease in the rural parts of the area did not exceed 4·4 in the same number living. Proceeding to deal with the fatality of particular diseases, as shown by their recorded death-rate, Mr. Phelps emphasises the need of extreme caution in deducing conclusions from figures which cannot be regarded as otherwise than mere approximations to the truth. Speaking generally, however, we note that in the American registration area the fatality from enteric fever, diphtheria, tuberculous phthisis, and pneumonia has recently shown a marked decrease, whilst that from cancer, heart disease, diarrhœa, and enteritis has, on the contrary, considerably increased. With respect to the mortality from diseases of early infancy, Mr. Phelps remarks that "the recent talk about a vigorous campaign against infant mortality has not yet produced any appreciable results in the American community at large." In support of Professor Irving Fisher's estimate that about 40 per cent. of existing American mortality is preventable, the author remarks that "never before in the entire history of the country have so many agencies for social and sanitary uplifting been in evidence; never before have so many of the more intelligent class of Americans been actively identified with such movements. But, at the present rate," he pertinently asks, "how long will it take for this thinking handful of Americans to arouse and leaven the general mass of this country's population?"

[1] Analysis of Some Phases of American Mortality Statistics, 1900–1908, by Edward Bunnel Phelps, M.A., F.S.S. Reprinted from the American Underwriter, vol. xxxii., No. 4, December, 1909.

THE MEDICAL INSURANCE COMMITTEE.

A MEETING of the Medical Insurance Committee was held on Wednesday, April 27th, at the offices of the British Medical Association, when the report of the chairman, Dr. G. E. Haslip, was read and adopted. The report referred first to the death of the late chairman, Dr. Radcliffe Crocker, in whom the committee lost a colleague who always exhibited great practical interest in, and enthusiastic confidence as to the ultimate success of the objects in view. These objects, it may be briefly stated, are to obtain, by acting as agents, favourable terms in all forms of insurance for medical men, while retaining out of the agency rebates a small percentage to be employed in charitable movements where the medical profession is interested. The report showed that during the year the business of the committee has been satisfactory and progressive in all directions. The total increase of premium income reached some £725. Previous to the period now under review motor-car insurance had not been touched, but in November, 1909, the committee was able to issue through Lloyds a policy against all motoring risks which at once proved popular, and it seems that there is a reasonable possibility of this branch of the work developing to a valuable extent. During the two months of 1909 the premium income from this source reached £236, while for the three months of the current year it has already reached £650. As to the working expenses of the agency, postages naturally show a slight increase, while with the extended business more clerical assistance has been necessary. In connexion with the business of personal accident and employers' liability insurances, results tend to confirm the earlier experience that the renewal business involves considerable labour and correspondence, as the percentage of

variation year by year is considerable. Stationery and printing have cost less, but during the year 1908 a considerable portion of the initial outlay was brought into the accounts. The report points out that, having regard to the small amount of commission retained by the Medical Insurance Committee to cover working expenses, it was hardly contemplated that any large reserve could be built up. By the strictest economy, at the end of 1909, after providing for all liabilities, there was a surplus of £85 11*s.* 3*d.* It is true this is not a large amount, but since the committee has been at work it has returned in the form of rebates on premiums to those taking advantage of insuring through the agency a sum of over £500—a result by itself that fully justifies the existence of such an agency. During the past year the committee has been strengthened by the addition of Dr. D. J. Mackintosh, M.V.O., Mr. Hugh R. Ker, and Dr. Frederic Hewitt, M.V.O., all these gentlemen kindly consenting to serve. It only remains to point out that the future prosperity of the Medical Insurance Committee must depend on the support it receives from the medical profession. The terms offered by the committee in all forms of insurance are exceptionally advantageous, and those who avail themselves of them can not only effect a saving of a considerable extent to themselves but will enable the committee to carry out its original object—to devote after paying working expenses any surplus to suitable medical charities. The committee voted a donation of £10 10*s.* to the British Medical Benevolent Fund, £10 10*s.* to the Royal Medical Benevolent Fund of Ireland, £10 10*s.* to the Birmingham Medical Benevolent Society, and £15 15*s.* to the Guild in connexion with the British Medical Benevolent Fund. The five guineas allocated to this Guild in excess of the other donations were a recognition that the work had been recently started and without funds to meet the initial expenditure.

LEPROSY IN NEW SOUTH WALES IN 1908.

SOME interesting facts relating to leprosy in Australia are given in the annual report for 1908[1] recently received by us from Dr. J. Ashburton Thompson, chief medical officer to the Government of New South Wales. At the beginning of 1908 22 lepers remained under detention in the lazaret at Little Bay, which is situated some nine miles from Sydney. Two fresh cases were admitted during the year, 1 died and 3 were repatriated to the New Hebrides, leaving 20 patients in the lazaret at the end of the year, 12 of whom were whites and 8 coloured. A series of clinical and etiological notes of the cases admitted in 1908, together with detailed "surveys" of the white patients still under treatment, are appended to the report. A summary is also given showing the number of persons who have been isolated on account of leprosy in the lazaret since 1883, along with the number of deaths and discharges in each of the years included in the period. A tabular statement is furnished giving the number of lepers who came under observation during 1908 in the Commonwealth of Australia. From this it appears that in addition to the two new cases already mentioned as having occurred in New South Wales, 23 others were reported from Queensland and 3 from Western Australia; no fresh cases were recorded in Victoria, South Australia, or Tasmania during the year. As appendices to his annual report Dr. Thompson reproduces two papers, the first of which was read by him before the International Dermatological Congress at Berlin as far back as 1904, entitled, "A Review of Leprosy in Australia during the Ten Years 1894 to 1903, and a Description of the Measures in Force there for the Control of the Disease." It is explained that this paper has been reprinted for the reason that it was not generally accessible and also "because the account of the laws and penalties as regards leprosy throughout the Commonwealth (which is still as accurate as it was four years ago) is a necessary addition to the records contained in this series of annual reports." The second paper was read by Dr. Thompson at the Second International Conference on Leprosy at Bergen last year, and in it he relates his experience of a trial of Professor Deycke's nastin treatment in three cases of tuberous leprosy and in one of pure nerve leprosy. In none of the four instances could an appreciable benefit be ascribed to the treatment, although its use in the cases was prolonged respectively for ten, eight, six, and nine months. In Dr. Thompson's hands nastin is alleged to have behaved as an inert substance. This paper is illustrated by photographs and charts.

[1] Eighteenth Report of the Board of Health on Leprosy in New South Wales for the Year 1908. By Dr. J. Ashburton Thompson.

A DANGEROUS DRY SHAMPOO.

ANOTHER example of silly and dangerous lay advice is given in a letter which we publish this week from Dr. V. H. Veley. Gasolene is recommended for giving the hair a dry shampoo. As Dr. Veley points out, gasolene cannot be purchased by the public. Its use for any general purpose has been strictly prohibited owing to its giving off an inflammable vapour even below ordinary room temperature, say 15° C., or 60° F. But clearly some other petrol is meant which would be sure to be equally dangerous for all practical purposes as, unless it were rapidly volatile, it would not answer as a satisfactory dry shampoo at all. It is true that a note of warning is given, for it is recommended in our contemporary that the shampooing operation be done in daylight, and further, that the ears should be stopped with cotton wool during the process, as some people are apt to find that the vapours affect their hearing; but such directions, even if they are heeded, convey to the public very little idea of the extreme risk involved by the use of such a highly and easily inflammable fluid. Pretty girls, to whom this sinful advice is particularly addressed, would be well advised to eschew the use of highly inflammable materials for the cleansing of the hair. As we have pointed out before, it is difficult to understand why the public, pretty or otherwise, does not give such a perfectly safe and effective mixture as distilled water, spirit, and ammonia a trial.

DR. ROBERT FLETCHER.

THE announcement that the Royal College of Surgeons of England had conferred the honorary gold medal upon Dr. Robert Fletcher in recognition of his exceptional services to the profession calls attention to a man who has had a career of great interest. Born in Bristol in 1823, Dr. Fletcher received his professional education at the Bristol School of Medicine, and took the diploma of the Royal College of Surgeons in 1844. After practising for a time in England he went to the United States and settled at first at Cincinnati; at the outbreak of the Civil War he joined the 1st Ohio Infantry and served throughout the war. In 1876 he became associated with Dr. John S. Billings in the Surgeon-General's Library, where for nearly 30 years he has been engaged in bibliographical work of a unique character. Every single volume of the Index Catalogue of the Surgeon-General's Library has passed through his hands, and he has been editor of the second series. In the very first volume published (1880) Dr. Billings acknowledges the great debt the work owed to Dr. Fletcher. He was associated with Dr. Billings in the editorship of the first series of the "Index Medicus," and he has been responsible, with Dr. Garrison, for the issue of the second series. He has written extensively on anthropology and folk-lore subjects. He has been greatly interested in medical jurisprudence, on which subject

he has lectured for some years at the Johns Hopkins Hospital Medical School. Though in his eighty-third year, Dr. Fletcher is able to continue his work at the Surgeon-General's Library, surrounded by all the things which, as Shakespeare says, should accompany old age—honour, love, obedience, troops of friends.

THE REGISTRAR-GENERAL'S WEEKLY RETURNS.

THE Registrar-General has since the last census in 1901 published weekly returns of vital statistics relating to the 76 towns of England and Wales which then had an enumerated population amounting to 50,000 persons. From March 31st last the area and population dealt with in these returns have been somewhat increased. At that date the municipal borough of Dewsbury was extended, and as the area now constituting the borough contained at the time of the last census a population exceeding 50,000, this town has been added to the list of 76 towns recently dealt with in these returns; its population in the middle of this year is estimated at 51,224. At the same date the newly constituted county borough of Stoke-on-Trent was substituted in these returns for the county borough of Hanley. The county borough of Stoke-on-Trent, as now constituted, includes, in addition to the county borough of Hanley, the late municipal boroughs of Burslem, Longton, and Stoke-upon-Trent, the urban district of Tunstall, and the greater part of that of Fenton. Thus the new county borough includes an estimated population of 245,726, among which pottery manufacture is the prevailing industry. These weekly returns will therefore, until further changes are rendered desirable by the results of next year's census, relate to 77 instead of 76 of the largest towns in England and Wales, having an aggregate population estimated to the middle of this year at 16,940,895 persons.

A SPECIAL meeting of the Royal Society of Medicine will be held on May 18th, at 5 P.M., at Morley Hall, George-street, Hanover-square, W., when Sir Almroth Wright, F.R.S., will open a discussion on Vaccine Therapy, its Administration, Value, and Limitations. The discussion will be continued on May 25th, June 1st, June 8th, and June 15th. The council has arranged for a number of Fellows to speak on the above days. Any Fellow who wishes to take part in the discussion is requested to communicate with the honorary secretaries.

Dr. Pestalozza of Rome and Dr. Martin of Geneva have been elected corresponding members by the Paris Academy of Medicine.

THE forty-third annual meeting of the Canadian Medical Association will be held in Toronto on June 1st, 2nd, 3rd, and 4th.

HEALTH OF ROTTERDAM.—Mr. Turing, the British Consul, reports that the population of Rotterdam on Dec. 31st, 1909, amounted to 417,783. The mortality rate in 1909 compared very favourably with that of the previous year, being 12·2 against 13·3 per 1000, and was the lowest ever recorded in the city. This very satisfactory condition was the more worthy of notice because of the fact that an outbreak of Asiatic cholera occurred on August 20th, resulting in 15 fatal cases. It was due to the energetic measures adopted by the municipal authorities that the course of the epidemic was so soon arrested, the last fatal case occurring on Sept. 4th. The outbreak was due to the drinking of impure water from the river, and this has led to the issue of orders by the town council instructing all owners and skippers of inland craft to provide themselves with supplies of filtered water from the municipal waterworks—a measure which will not only beneficially affect the large floating population, but will also tend to safeguard the health of the city generally.

THE ORIGIN, SCOPE, AND AUTHORITY OF THE BRITISH PHARMACOPŒIA.

BY H. WIPPELL GADD, F.C.S.,
OF THE MIDDLE TEMPLE, BARRISTER-AT-LAW.

THE British Pharmacopœia is published under the direction of the General Council of Medical Education and Registration of the United Kingdom, pursuant to the Medical Acts, 21 & 22 Vict. Cap. XC. (1858) and 25 & 26 Vict. Cap. XCI. (1862).

Section LIV. of the Medical Act, 1858, enacted that:—

> The General Council shall cause to be published under their direction a Book containing a List of Medicines and Compounds, and the manner of preparing them, together with the true weights and measures by which they are to be prepared and mixed, and containing such other matter and things relating thereto as the General Council shall think fit, to be called "The British Pharmacopœia"; and the General Council shall cause to be altered, amended, and republished such Pharmacopœia as often as they shall deem it necessary.

The Medical Act, 1862, recited in its preamble and enacted, *inter alia*, as follows:—

> Whereas different Pharmacopœias have hitherto been in use in England, Scotland, and Ireland, published in England under the direction of the Royal College of Physicians of London, and sanctioned by an Order of Her Majesty in Council, published in Scotland under the direction of the Royal College of Physicians of Edinburgh, but without any legal sanction, and published in Ireland under the direction of the King and Queen's College of Physicians in Ireland, and sanctioned by Act of Parliament: And whereas the Pharmacopœia to be published by the said Council is intended to supersede the above-mentioned Pharmacopœias: And whereas it is expedient to incorporate the said Council, and to make such provisions as are hereinafter contained with respect to the said British Pharmacopœia: Be it enacted ..... the British Pharmacopœia, when published, shall for all purposes be deemed to be substituted throughout Great Britain and Ireland for the several above-mentioned Pharmacopœias.

The purpose of the British Pharmacopœia is well stated in the preface thereof:—

> It is intended to afford to the members of the medical profession and those engaged in the preparation of medicines throughout the British Empire one uniform standard and guide, whereby the nature and composition of substances to be used in medicine may be ascertained and determined.

In order to ensure that this purpose should be fulfilled, it was enacted by Section XV. of the Pharmacy Act, 1868 (31 & 32 Vict. c. 121) that:—

> Any person who shall ..... compound any medicines of the British Pharmacopœia except according to the formularies of the said Pharmacopœia, shall for every such offence be liable to pay a penalty or sum of five pounds .....

It should be noted that this does not provide a penalty for selling an improperly compounded medicine, but only for the wrongful compounding. This offence is obviously difficult to prove, and hence the provision has seldom, if ever, been used, and has become a dead-letter.

Another attempt to enforce by penalties the authority of the British Pharmacopœia was made in 1875, when the sixth section of the Sale of Food and Drugs Bill, as submitted to Parliament, read as follows:—

> No person shall sell any compound article of food which is not composed of ingredients in accordance with the demand of the purchaser, under a penalty of twenty pounds. No person shall sell any compounded drugs except the same shall be compounded in accordance with the demand of the purchaser, or with the prescription in writing of a registered medical practitioner, *or with the regulations prescribed by the British Pharmacopœia issued by the General Medical Council*, or in Great Britain with a basis to be laid down by the Council of the Pharmaceutical Society of Great Britain or the Privy Council, or in accordance with the provisions of the Pharmacy Act, 1868, or in Ireland in accordance with the Act of the Session of the thirty-third and thirty-fourth of Victoria, chapter 26, under a penalty of twenty pounds.

This clause was, however, entirely remodelled during the passage of the Bill through Parliament, and in the Act[1] all direct reference to standards is omitted, and the offence specified is that of selling any article of food or any drug which is not of the nature, substance, and quality of the article demanded by the purchaser.

It is true that in the sixth section of the Act it is provided that the offence of selling to the prejudice of the purchaser cannot be committed "where the food or drug is compounded as in this Act mentioned," but this proviso has been held to be meaningless and therefore inoperative. The point was raised in the case of Beardsley *v.* Walton and Co. (1900, 2 Q.B.D. 1), in giving judgment in which Channell, J., remarked: "There is nothing in the Act as to how drugs are to be compounded. The only way in which this omission

[1] Sale of Food and Drugs Act, 1875 (38 & 39 Vict., c. 63).

can be accounted for is that the Bill as originally drafted contained a definition of the expression 'compounded drugs' which was dropped out of it during its progress through Parliament, while the expression 'drug compounded as in this Act mentioned" was left in by an oversight. The result is that Subsection 3 of Section 6 has practically no operation."

In the course of their duties, perhaps no more difficult task confronts public analysts than that of finding a standard by which the quality and strength of substances submitted to them for examination can be gauged. The difficulty is in some degree met for certain food substances by regulations made by the Board of Agriculture, under powers conferred upon it by Section 4 of the Sale of Food and Drugs Act, 1899. Thus it is laid down that: "When a sample of milk ..... contains less than 3 per cent. of fat, it shall be presumed, ... until the contrary is proved, that the milk is not genuine." There is no such presumptive standard for drugs, but public analysts have very generally taken the British Pharmacopœia as a convenient guide, by comparison with the standards and descriptions of which they can gauge the quality of medicinal substances purchased by inspectors under the Sale of Food and Drugs Acts.

This use of the Pharmacopœia has been challenged in several contested cases, which I propose briefly to review. The earliest of these cases is White *v.* Bywater (1887, 19 Q.B.D. 582). In this a purchaser asked for some tincture of opium without specifying that he wanted it prepared according to the standard of the British Pharmacopœia. The seller supplied an article which on analysis was found to be deficient both in opium and spirit when compared with the tincture made as specified in the British Pharmacopœia. Evidence was given that tincture of opium was a well-understood term in the trade, and that the article sold by the defendant was not of the nature, substance, and quality of tincture of opium as understood by persons usually dealing in that article. It was held by Lord Coleridge, C.J., and A. L. Smith, J., that the respondent ought to have been convicted of an offence under Section VI. of the Sale of Food and Drugs Act, although the purchaser had not asked for tincture of opium prepared according to the standard of the British Pharmacopœia; and A. L. Smith, J., said: "Tincture of opium must mean the article known in commerce as tincture of opium. The thing supplied was not tincture of opium of commerce, but an inferior article."

In Dickins *v.* Randerson (1901, I.K.B. 437) a chemist managing a branch of Taylor's Drug Stores, Limited, was asked for "mercury ointment," and supplied an ointment containing 12·5 per cent. of mercury, whereas according to the formula in the British Pharmacopœia it should contain 48·5 per cent. Evidence was given to show that it was the usual practice amongst chemists to supply the weaker ointment unless the stronger variety was prescribed or specially asked for, and that the indiscriminate distribution of the official ointment would be a source of considerable public danger. The defendant was, however, convicted, and on appeal it was held by Bruce and Phillimore, JJ., rightly so. Phillimore, J., said: "If a drug is to be found in the Pharmacopœia, and if that drug is asked for, that drug must be supplied; and if it is not sold with the ingredients and in the proportions prescribed by the Pharmacopœia, there is at least *primâ-facie* evidence that what is sold is not of the nature, substance, and quality which was demanded."

In Boots, Cash Chemists (Southern), Limited *v.* Cowling (1903, 67 J.P. 195) the defendants sold liniment of soap, made with methylated spirit instead of with rectified spirit, as prescribed by the British Pharmacopœia. Liniment of soap is one of the few articles in the manufacture of which the Board of Inland Revenue allows methylated spirit to be used, and such methylated liniment is extensively sold, and being, of course, used externally only, is as efficient a preparation as the one made with rectified spirit. The defendants wished to call a number of witnesses to prove that there was a commercial standard for liniment of soap different from that of the British Pharmacopœia, but the magistrate refused to receive this evidence, holding that he was bound so to refuse by the decision in Dickins *v.* Randerson (*vide supra*). The defendants appealed to the Divisional Court, the appeal being heard by Lord Alverstone, C.J., and Wills and Channell, JJ., who decided that the evidence ought to have been received, but expressly refrained from giving any opinion as to its value, and sent the case back for rehearing. Lord Alverstone, C.J., said: "It was quite clear that Phillimore, J., never meant to lay down in that case (Dickins *v.* Randerson) that nothing could be looked at except the British Pharmacopœia. On the other hand, if it were a sale of some drug recognised by a special name in the Pharmacopœia a very strong *primâ-facie* case would be made out as to what the drug ought to contain. Any evidence, therefore, tendered to show that a commercial standard did exist different from that prescribed by the Pharmacopœia ought to be received. To say that no evidence of this kind was admissible, because of the decision in Dickins *v.* Randerson, was, in the opinion of the court, going too far." Subsequently the case was reheard by the magistrate, who, in spite of this evidence, convicted the defendants on the ground that the standard formula was that of the British Pharmacopœia, and that it had not been proved that there was any other commercial standard, nor was it reasonable to expect that there could be two commercial standards.

A singular case was that of Hudson *v.* Bridge (1903, 67 J.P. 186), in which the article sold was vinegar of squills, which was found to contain 2·5 per cent. of acetic acid, whereas it was alleged that it should have contained 4·27 per cent. of acetic acid. Obviously the acid is not the most active ingredient of this preparation, being rather the menstruum by which the potent drug squill is exhausted, and the vehicle in which it is exhibited. Moreover, evidence was given to the effect that some of the acetic acid is lost, as such, in the process of manufacture, and that a change takes place in the vinegar, even when carefully kept, which results in the further reduction of the quantity of free acetic acid present. The defendant was, however, convicted, but on appeal it was held that the justices were wrong. The Lord Chief Justice, in giving judgment, expressed his opinion that it was not material that the acetic acid had diminished, as the vinegar of squill as a drug was none the worse.

The general effect of these cases is, therefore, that when a compound medicine is demanded by a name which occurs in the Pharmacopœia, an article made in accordance with the formula, and answering the tests, if any, given in the Pharmacopœia, is presumed to be required, and that only very strong evidence to the contrary will suffice to rebut such presumption.

With regard to simple drugs there are few, if any, authoritative cases, and the question of the authority of the Pharmacopœia is complicated by the fact that many articles named therein have uses other than medicinal.

Thus in Fowle *v.* Fowle (1896, 75 L.T. 514) the defendant, a grocer, sold some beeswax which on analysis was found to contain about equal parts of true beeswax and paraffin. The magistrates dismissed the case on the ground that beeswax was not a drug, although evidence had been given before them to the effect that it is used in the preparation of substances for medicinal use and is included in the British Pharmacopœia. On appeal, the court (Grantham and Wright, JJ.) held that it is a question of fact for the justices to decide whether, in all the circumstances of each case, the article in question is a drug, and that in the circumstances of this case they were right in deciding that the beeswax was not a drug. "It was sold by a grocer at a little country shop. The grocer did not make it. He said he did not know what its constituents were. The justices were right." The implication apparently is, that if the sale had been made by a pharmacist the result might have been different.

A further difficulty arises from the fact that many of the standards of the Pharmacopœia for crude drugs are restrictive rather than absolute; that is to say, they are framed to include not all normal genuine samples but only certain selected ones. Thus, opium of the British Pharmacopœia is not simply "the juice obtained by incision from the unripe capsules of Papaver somniferum," but only such juice as when dried yields a powder, which on being tested by the official method is found to yield approximately 10 per cent. of anhydrous morphine. When this standard was first established there was some outcry amongst drug merchants to the effect that it would have the result of lowering the quality of commercial supplies; but the General Medical Council has nothing to do, at least directly, with the exigencies of commerce, and the establishment of a restrictive standard for opium achieved the desideratum of ensuring a uniform product for medicinal purposes. On the other hand, the Pharmacopœial monograph for rosemary oil excludes by its

characters and tests the Spanish variety. But pure rosemary oil comes from Spain in enormous quantities and is of the very greatest service to soap manufacturers, besides being used for many other non-medicinal purposes, and there is no reason why the paramount duty of securing uniformity in therapeutic agents should involve hardship upon legitimate users of such for industrial and commercial purposes.

A little consideration will show that the General Medical Council cannot take general names and apply them to particular varieties any more than a manufacturer or dealer can appropriate ordinary English words to special proprietary brands. Thus, aconite root of the Pharmacopœia is "the root of aconitum napellus, collected in the autumn from plants cultivated in Britain and dried," but it would degrade the English language and confuse botanical science if it were insisted that the words "aconite root" might not properly be applied to roots of other species of the genus *Aconitum*, which have been collected at other times of the year and in other countries.

It should be made quite clear in the next edition of the Pharmacopœia that the standards laid down therein are for medicinal substances, when sold as such, alone. Pending this, each case will have to be decided on its merits, but it may safely be assumed that any drugs mentioned in the Pharmacopœia when sold for medicinal purposes should conform to the standards, descriptions, and tests of the Pharmacopœia, provided always that these are consistent *inter se*.

CENTRAL MIDWIVES BOARD.

SPECIAL meetings of the Central Midwives Board were held at Caxton House, Westminster, on April 19th and 20th, Dr. F. H. CHAMPNEYS being in the chair.

The following midwives were struck off the roll: Margaret Barnett, Esther Farrall, Mary Ann Neale, and Elizabeth Williams, that being in attendance as midwives at confinements, the children suffering from inflammation of the eyes, the midwives did not explain that the cases required the attendance of registered medical practitioners, nor did they hand to the nearest relatives or friends present the form of sending for medical help, properly filled up and signed, in order that these might be immediately forwarded to medical practitioners as required by Rule E 19 (5). Henrietta Chinn, that being in attendance as a midwife at a confinement she was uncleanly in person, house, clothing, and appliances. Margaret Davies and Esther Letherin for drunkenness. Annie Hardstaff, that being in attendance as a midwife at a confinement, the child suffering from inflammation about the navel, she did not send for a medical man. Margaret Middlemiss, that being in attendance as a midwife at a confinement, the presentation being abnormal, she did not send for a medical man. Sarah Timson, that having received a written direction from Dr. Arthur B. King, medical officer of health of the urban district of Watford, to discontinue attendance at any confinements for one week, and to disinfect herself, her clothing, and her appliances to the satisfaction of the local supervising authority, on account of one of her children suffering from diphtheria, she nevertheless attended three confinements during the five days following the receipt of Dr. King's direction, without having undergone adequate disinfection. Mary Weddell, that being in attendance as a midwife at a confinement, the patient suffering from excessive bleeding before the birth of the child, she did not send for a medical man. Elizabeth White. that being in attendance as a midwife at a confinement, the child having been born apparently dead, she made no effort to carry out any method of resuscitation. Mary Backhouse, that being in attendance as a midwife at a confinement and present on the occurrence of rigor she did not take the patient's temperature nor send for a medical man. Sarah Beeston, that being in attendance as a midwife at a confinement, the lochia being persistently offensive from the first, she did not send for a medical man. Ann Foley, that being in attendance as a midwife at a confinement, the patient suffering from severe rigor and sickness, and subsequently from abdominal pain and constant sickness, she did not send for a medical man. Frances Rebecca Llewellyn, that having been engaged as a midwife at a confinement, the patient suffering from recurrent hæmorrhages, she did not send for a medical man. Susanna Thomas, that without reasonable excuse and with intent to evade supervision, she persistently refused to submit her bag and appliances for inspection by the duly appointed officer of the local supervising authority.

The following midwives were cautioned after charges against them had been considered: Elizabeth Baverstock, Adelaide Harker, Arabella Matilda Hopton, Sarah Jane Long, and Sarah King.

Elizabeth Mary Dean, Elizabeth Hill, Hannah Howe, Elizabeth Wilding, Elizabeth Anderson, Mary Frankham, Alice Turner, and Sarah Wainwright were censured after charges alleged against them had been considered.

An ordinary meeting of the Board was held on April 21st, Dr. CHAMPNEYS being in the chair.

A letter was read from Dr. H. Scurfield, medical officer of health of Sheffield, in which he observed that "as midwifery is neither medicine nor surgery he did not know whether it would be considered 'covering' for a medical man to keep an unqualified dispenser who attended midwifery cases." Dr. Scurfield also pointed out that it did not appear from Section 1 of the Midwives Act, 1902, that it was an offence for an unqualified male midwife to undertake midwifery. The Board directed the secretary to reply that the best course for Dr. Scurfield to follow would be to apply to the General Medical Council.

A letter was considered from a certified midwife advertising a patent medicine. The Board decided that the midwife be informed that if she does not forthwith discontinue the use of the letters C.M.B. affixed to her name and the advertising of the patent medicine she will be cited to appear before the Board.

Letters were read from the inspector of midwives for Norfolk as to the period of suspension of a midwife to which the Board had taken exception.[1] The Board decided that the local supervising authority be informed that no suspension should be for a longer period than is necessary for adequate disinfection.

The Board having considered the procedure on application to be certified under Rule B. 2, and the fee to be charged, decided: (1) that the form of application, and the certificate in support thereof, be the same as used in similar applications down to March 31st, 1905; (2) that the fee payable be 1 guinea; and (3) that the grant of a certificate without requiring training or examination be limited to those who have been practising, and desire to continue to practise, as midwives in England and Wales.

Dr. Champneys was unanimously re-elected Chairman of the Board for the year ending March 31st, 1911.

MEDICINE AND THE LAW.

The Sale of Poisons and the Name of the Seller.

THE Divisional Court recently heard an appeal against the conviction of a druggist by a magistrate at a London police court for selling poison in a bottle upon the label of which his name did not appear. The point at issue in the case was whether the provisions of Section 17 of the Pharmacy Act, 1868, were satisfied by the use on the label of the trade name of the defendant, whose surname was Edwards, but who carried on business under the name of Godfrey. The Pharmaceutical Society, the prosecutors in the case, contended that the true name of the seller must be used, the words of the section being "the name and address of the seller." The court, after listening to counsel on both sides, allowed the appeal and quashed the conviction, the Lord Chief Justice in doing so saying that the object of the Pharmacy Act in imposing regulations to govern the sale of poisons was to protect the public, and that in providing for the keeping of records of the sale, including the signature of the purchaser, it was intended that it should be possible to trace the poison to the address where it was sold. He was of the opinion, therefore, that where a trade name was used "the name of the seller" would be the name under which the sale was effected. He pointed out that it had been held that a corporation could sell poisons and was liable to prosecution if in doing so it did not comply with the section. In the case before the court Mr. Edwards traded under the name of Godfrey, and

[1] THE LANCET, March 26th, p. 898.

it was a proper compliance with the section to place the name of Godfrey on the label. His lordship recognised the care which the magistrate had devoted to the consideration of the case, but was of opinion that the conclusion at which he had arrived was a wrong one. Mr. Justice Bray and Mr. Justice Pickford agreed with Lord Alverstone in allowing the appeal.

THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.

Provision in Wandsworth.

THE Education Committee of the London County Council on April 27th had under consideration further arrangements for the medical treatment of children in districts remote from hospitals. The medical practitioners of Wandsworth submitted a scheme, similar to those already approved for Hampstead and Norwood, for the treatment of children in their district. It was proposed to make arrangements for 1500 cases—500 ear, nose, or throat, and 1000 eye and ringworm cases. The payment for the former would be on the basis of £50 per annum for each medical man working one half day a week, and a capitation fee of 2*s*. Arrangements were to be made for the treatment of ringworm cases at the respective surgeries of the medical men at an inclusive fee of 17*s*. a case. The scheme was approved, but as it was discovered that no provision had been made in this or the other schemes submitted by medical practitioners for reports to the Council as to the results of treatment, the chairman of the committee promised to come to some arrangement. In the case of the hospitals, Mr. Jackson said, results were being tabulated.

The Hampstead Experiment.

The Children's Care Committee reported that the period during which the Hampstead Council of Social Welfare agreed to provide treatment for school children in Hampstead came to an end in March, 167 children having received medical attention. An expression of thanks had been conveyed to those responsible for the experiment. The committee passed no verdict on the experiment, which, of course, has been superseded by the arrangements entered into with the local medical men.

Withdrawal of the Westminster Ophthalmic Hospital.

The governing body of the Royal Westminster Ophthalmic Hospital wrote on March 3rd withdrawing the offer, accepted by the Council at the end of last July, to provide for one year treatment for 2000 children a year, free of charge to the Council. The arrangements were put into operation from August 23rd, 1909. In notifying their withdrawal the governing body expressed their willingness to consider any suggestions the Council might make. The committee understood that the hospital authorities would be prepared to continue treatment in return for financial aid. In view, however, of the proximity of the Royal Westminster Ophthalmic Hospital to Charing Cross Hospital, where provision had been made for 1000 cases, and to the provision made at other neighbouring hospitals, the committee thought it would not be possible at present to ensure that sufficient cases would be available to justify a financial agreement being entered into. They, therefore, recommended that the hospital authorities be thanked and informed accordingly, and this was agreed to.

British Medical Association's Protest.

The Children's Care Committee reported the receipt of a letter, dated March 8th, from the British Medical Association protesting against the arrangements made by the Council with the hospitals for medical treatment, and stating that the experience of medical practitioners showed the insufficiency of inquiries by hospital almoners to establish in all cases the ability or inability of parents to pay for treatment. The committee had informed the Association that the Council's plan, before children were referred to hospitals, was that local care committees and head teachers should satisfy themselves that the cases were suitable for hospital treatment. There was therefore a double check against the abuse of hospitals.

Assistant School Doctorships Vacant.

The Education Committee decided to advertise inviting applications to fill vacancies for 24 assistant school doctors. Hitherto it has been mentioned in the advertisements that promotions to the posts of school doctors would be made from among the assistant school doctors, but in order to preserve freedom of action the committee decided to omit the statement. Under the scheme adopted in November, 1908, holders of appointments as school doctors or assistant school doctors are not eligible for reappointment after three years' service.

Finance Committee and Dental Treatment.

In introducing the annual estimates of income and expenditure at the meeting of the London County Council on April 26th Mr. Hayes Fisher, chairman of the Finance Committee, prophesied the continued rise of the education rate owing to the cost of teachers' salaries, the feeding of necessitous children, and medical inspection and treatment. In respect of the latter £21,000 had been included in the present estimates. Nothing had been included in respect of dental treatment, but they must expect such an item in future estimates.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 28th, 1832.

ROYAL INSTITUTION OF GREAT BRITAIN.

STRUCTURE AND FUNCTIONS OF THE INFUSORIA.

On the 6th instant Mr. THOMAS BELL read a paper on the structure and functions of the *infusoria*, a class of animalcula discovered with the aid of powerful lenses in animal and vegetable infusions. Until very recently the most perfect microscopes were incapable of showing more of these minute beings than their mere existence. They were supposed to have no proper form, and their spherical shape was said to be due to the pressure of the surrounding medium. These creatures were first discovered by Lewenhoeck. His researches were ingeniously followed by La Marque and his followers, who, with singular daring, endeavoured to apply the new facts to the construction of a scheme of necessity in the organization of living beings. These vivacious dots or monads were supposed to be the ultimate elements of animate bodies, and to supply by their aggregation the materials of every form of life. The late discoveries of the German physiologists have effected a signal overthrow of these doctrines, for these apparently indivisible points have by means of improved instruments been proved to possess a complete organization, as difficult to be accounted for by the hypothesis of necessity as the human frame itself. This end was obtained by the simple expedient of feeding the animalcules with coloured liquids. A solution of pure indigo is the most eligible fluid, and great caution is requisite to prevent the introduction of any metallic or medicinal pigment, for their destruction would be the immediate consequence, and the desired results could not be obtained. These precautions taken, a variety of appearance was observed in the hitherto seemingly homogeneous globules. In some, numerous spots became evident; these are the digestive cavities or stomach; others present a different character, and one digestive cavity alone is exhibited. The observer succeeded in detecting a mouth and an anus, and the rudiments even of a nervous system were perceived. The first and most simple class is named *polygastrica*, from the great number of stomachs; the second and more complicate is denominated *rotatoria*, from the nature of their movements. Relating to the functions of this second class, numerous facts of great interest were ascertained. They were found to exhibit all the principles of reproduction exemplified in other animals. When divided, each part, as in the planaria genus, became a perfect animal. The propagation by germ or bud was also frequently exemplified, and their ovicula had been distinctly demonstrated. The interest of these researches will be enhanced, when it is stated, that these objects are so minute, that the space occupied by a single drop of distilled water is adequate to contain no less than five hundred millions, and that a cubic inch would include *eight hundred thousand millions*, a number a thousand times greater than

that representing the population of the globe. Mr. Bell appended some remarks on the tendency which the rash explication of natural phenomena, by a principle of necessity, especially in animated nature, has to debase the character of philosophy, and to deprive the mind of that exalted pleasure which it derives from the contemplation of infinite design.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8195 births and 4467 deaths were registered during the week ending April 23rd. The annual rate of mortality in these towns, which had steadily increased in the five preceding weeks from 13·5 to 15·0 per 1000, declined again to 13·7 in the week under notice. During the first three weeks of the current quarter the annual death-rate in these towns averaged 14·5 per 1000; in London the mean rate during the three weeks did not exceed 14·2 per 1000. The lowest recorded annual rates of mortality during last week in these 77 towns were 5·7 in Burton-on-Trent, 6·5 in Handsworth, 6·6 in Walthamstow, and 7·7 in York; the rates in the other towns ranged upwards, however, to 19·8 in Liverpool, 20·3 in Merthyr Tydfil, 20·6 in Preston, and 21·3 in Oldham. In London the recorded death-rate last week did not exceed 13·1 per 1000. The 4467 deaths registered last week in the 77 towns showed a decline of 405 from the number in the previous week, and included 345 which were referred to the principal epidemic diseases, against 333, 362, and 383 in the three preceding weeks; of these 345 deaths, 143 resulted from whooping-cough, 97 from measles, 40 from diarrhœa, 29 from diphtheria, 27 from scarlet fever, and 9 from enteric fever, but not one from small-pox. The mean annual rate of mortality in the 77 towns from these epidemic diseases during the week was equal to 1·1 per 1000, against 1·1 and 1·2 in the two preceding weeks. No death from any of these epidemic diseases was registered last week in Leicester, Walthamstow, Norwich, Hornsey, or in eight other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2·9 in Liverpool, Rochdale, and Stockton-on-Tees, 3·1 in Devonport, and 3·3 in Merthyr Tydfil. The fatal cases of whooping-cough in the 77 towns, which had been 151 and 143 in the two previous weeks, were again 143 last week; they caused annual death-rates equal to 1·3 in Birkenhead and in South Shields, 1·4 in Liverpool, 2·2 in Bootle, and 2·5 in Devonport. The 97 fatal cases of measles showed a decline of 20 from the number in the previous week; the highest death-rates from this disease last week were 1·3 in East Ham, 1·5 in Stoke-on-Trent, 1·8 in Bradford, and 2·6 in Merthyr Tydfil. The 40 deaths attributed to diarrhœa considerably exceeded the numbers in recent weeks. The deaths from diphtheria, which had been 35 and 39 in the two preceding weeks, declined to 29 last week and were fewer than in any previous week of this year; 9 occurred in London and its suburban districts and 2 each in Birkenhead, Manchester, Rochdale, and Preston. The 27 fatal cases of scarlet fever included 10 in London and its suburban districts, 3 in Liverpool and in Sunderland, and 2 in Manchester. Only 9 deaths in the 77 towns were last week referred to enteric fever and were fewer than in any previous week of this year. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily declined in the 27 preceding weeks from 2819 to 1535, had further fallen to 1510 on April 23rd; 196 new cases of this disease were admitted to these hospitals during last week, against 166 and 197 in the two preceding weeks. The Metropolitan Asylums Hospitals contained no case of small-pox on Saturday last. Of the 1226 deaths registered in London during the week under notice 277 were referred to pneumonia and other diseases of the respiratory system, showing a decline of 35 from the number returned in the previous week; these deaths were 43 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 35, or 0·8 per cent., of the deaths registered in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during the week were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, and in 53 other smaller towns; the 35 uncertified causes of death in the 77 towns included 7 in Birmingham, 4 in Liverpool and in Gateshead, and 3 in Stoke-on-Trent.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 969 births and 590 deaths were registered during the week ending April 23rd. The annual rate of mortality in these towns, which had been equal to 18·1, 18·2, and 18·5 per 1000 in the three preceding weeks, declined to 16·3 in the week under notice. During the first three weeks of the current quarter the death-rate in these towns averaged 17·7 per 1000, and exceeded by 3·2 the mean rate during the same period in the 77 largest English towns. The annual death-rates last week in these eight Scotch towns ranged from 7·8 and 13·2 in Leith and Aberdeen to 26·1 in Dundee and 26·2 in Greenock. The 590 deaths from all causes in the eight towns during last week showed a decline of 79 from the number in the previous week, and included 87 which were referred to the principal epidemic diseases, against 123 and 97 in the two preceding weeks. These 87 deaths were equal to an annual rate of 2·4 per 1000; the mean death-rate from the same diseases in the 77 English towns last week did not exceed 1·1 per 1000. These 87 deaths in the Scotch towns last week included 59 from measles, 16 from diarrhœa, 6 from whooping-cough, 4 from diphtheria, and 1 each from scarlet fever and "fever," but not one from small-pox. The fatal cases of measles, which had been 74 and 64 in the two preceding weeks, further declined last week to 59, which included, however, 24 in Dundee, 18 in Glasgow, 9 in Greenock, and 7 in Edinburgh. The 16 deaths attributed to diarrhœa exceeded the number in the previous week by 1; 7 occurred in Glasgow, 3 in Edinburgh, and 2 both in Dundee and in Aberdeen. The 6 fatal cases of whooping-cough corresponded with the number in the previous week, and included 2 in Glasgow and in Dundee. Three of the four deaths from diphtheria, showing a considerable decline from the numbers in recent weeks, were returned in Glasgow. The fatal case of scarlet fever and that referred to "fever" occurred in Glasgow; the death from "fever" was certified as cerebro-spinal meningitis. The deaths in the eight towns referred to diseases of the respiratory system, which had been 114 and 126 in the two preceding weeks, declined to 92 in the week under notice, and were 26 below the number in the corresponding week of last year. The causes of 10, or 1·7 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death did not exceed 0·8 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 643 births and 494 deaths were registered during the week ending April 23rd. The mean annual rate of mortality in these towns, which had been equal to 23·2 per 1000 in each of the two preceding weeks, declined to 22·4 in the week under notice. During the first three weeks of the current quarter the annual death-rate in these Irish towns averaged 22·9 per 1000, whereas the mean rate during the same period did not exceed 14·5 in the 77 largest English towns, and 17·7 in the eight principal Scotch towns. The annual death-rate during last week was equal to 24·3 in Dublin, 21·3 in Belfast, 23·3 in Cork, 13·2 in Londonderry, 19·1 in Limerick, and 29·2 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish town districts was equal to 22·3 per 1000. The 494 deaths from all causes in the 22 town districts last week showed a decline of 18 from the number in the previous week, and included 41 which were referred to the principal epidemic diseases, against 26, 34, and 39 in the three preceding weeks; these 41 deaths were equal to an annual rate of 1·9 per 1000; in the 77 English towns the mean rate from the same diseases last week did not exceed 1·1 per 1000, while in the eight Scotch towns it was equal to 2·4. The 41 deaths from these diseases in the Irish towns last week included 17 from whooping-cough, 9 from measles, 6 from diarrhœa, 4 from diphtheria, and 5 from "fever," but not one either from scarlet fever or small-pox. The fatal cases of whooping-cough in the 22 towns, which had been 15 and 9 in the

two previous weeks, rose again to 17 last week, of which 5 occurred in Dublin, 8 in Belfast, and 2 in Drogheda. The 9 deaths from measles were, however, fewer by 8 than the number in the previous week; they included 8 in Belfast. Of the 6 deaths attributed to diarrhœa, 3 occurred in Belfast and 2 in Dublin; and 2 of the 4 deaths from diphtheria were also returned in Dublin. A fatal case of typhus was registered both in Waterford and in Galway; and one each of enteric fever in Belfast and in Portadown. The deaths in the 22 towns referred to pneumonia and other diseases of the respiratory system, which had been 129 and 121 in the two preceding weeks, further declined to 118 last week. The causes of 15, or 3·0 per cent., of the deaths registered in the Irish towns last week were not certified; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent., and in the eight principal Scotch towns it was equal to 1·7 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: C. L. W. Bunton to the *Suffolk*, on recommissioning, and E. F. Mortimer to the *Carnarvon*, on recommissioning. Staff Surgeons: L. A. Baiss to the *Prince George* (temporarily), and S. T. Reid to the *Antrim*, on recommissioning. Surgeons: W. Bastian to the *Bacchante*, on recommissioning; J. E. Johnston lent to the *Circe*, temporarily; H. F. Briggs to the *Leander;* F. G. Hitch to the *Suffolk*, on recommissioning; G. F. Syms to the *Exmouth;* H. A. Kellond-Knight to the *Bellerophon;* J. H. Wright to the *Bulwark*, additional.

ARMY MEDICAL SERVICE.

Surgeon-General Philip M. Ellis retires on retired pay (dated April 23rd, 1910). Colonel James G. MacNeece to be Surgeon-General, vice P. M. Ellis (dated April 23rd, 1910).

ROYAL ARMY MEDICAL CORPS.

The under-mentioned Lieutenants, from the Seconded List, are restored to the establishment (dated April 1st, 1910):—Frederick R. Laing and John T. Simson.

Colonel W. G. Macpherson, C.M.G., from the London District, has been appointed Principal Medical Officer at Malta. Lieutenant-Colonel T. J. O'Donnell, D.S.O., from Quetta, has been appointed to command the station hospital at Aden. Lieutenant-Colonel C. E. Nichol, D.S.O., lately commanding the Royal Army Medical Corps Depôt and School of Instruction at Aldershot, has been appointed to command the station hospital at Maymyo. Lieutenant-Colonel W. C. Beevor, C.M.G., from Dalhousie, has joined at Bangalore. Major C. T. Samman, from Shorncliffe, has been appointed to command the station hospital at Dinapore. Major J. Grech, from Meerut, has been posted to the Western Command. Major E. M. Williams, from Fermoy, has embarked for India. Major H. J. Parry, D.S.O., from Pietermaritzburg, has been transferred to the home establishment and posted to the Southern Command. Major M. M. Lowsley has been transferred from Secunderabad to Ambala. Major F. J. Wade-Brown has taken up duty in the Cork District. Captain M. C. Wetherell has been appointed a Specialist in Electrical Science to the Seventh (Meerut) Division. Captain W. B. Fry, on arrival in Egypt, has been posted for duty under the Soudan Government and granted the local rank of Bimbashi. Captain F. C. Lambert, from Cape Town, has been posted to Cosham; and Captain P. J. Hanafin, from Wynberg, has been posted to the Southern Command. Captain W. MacD. MacDowall has been transferred from Buttevant to Devonport. Captain G. Baillie has embarked for a tour of service on the West Coast of Africa. Lieutenant A. L. Stevenson has been transferred from Dublin to the Curragh. Lieutenant C. E. L. Harding has been attached to the station hospital at Purandhur. Lieutenant M. Leckie has arrived in Egypt for a tour of service with the Egyptian Government.

INDIAN MEDICAL SERVICE.

Colonel D. ffrench Mullen, Deputy Principal Medical Officer, His Majesty's Forces in India, has been granted eight months' combined leave out of India. Major P. Dee has arrived home on leave. The services of Captain J. M. A. Macmillan have been placed permanently at the disposal of the Honourable the Chief Commissioner of the Central Provinces. Captain J. H. Burgess has been granted one year's leave out of India, and Captain A. Murphy, Medical Officer of the 103rd Mahratta Light Infantry, has been granted eight months' leave. Captain C. Barnes has arrived home on leave.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The undermentioned Lieutenants (on probation) are confirmed in that rank:—George Rollason, W. H. L. McCarthy, Ian D. Dickson, J. M'G. Scott, T. E. Guthrie, W. T. Graham, and C. S. Sandeman.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st South Midland Field Ambulance: Edward James Boome to be Lieutenant (dated Feb. 19th, 1910).

1st Scottish General Hospital: Captain Peter Mitchell, from the 1st Highland Field Ambulance, Royal Army Medical Corps, to be Captain (dated Feb. 1st, 1910). Captain Peter Mitchell to be Major (dated April 2nd, 1910).

4th Northern General Hospital: Captain Francis B. Cooper resigns his commission (dated Sept. 24th, 1909). Frank Alcock to be Captain, whose services will be available on mobilisation (dated Feb. 14th, 1910).

For attachment to Units other than Medical Units.—Thomas Hamilton Ward to be Lieutenant (dated March 1st, 1910). Lionel Henry Moiser to be Lieutenant (dated March 11th, 1910). William Townsend Storrs to be Lieutenant (dated Feb. 21st, 1910). Surgeon-Captain Frederick William Johnson, from the 8th Battalion, The Sherwood Foresters (Nottinghamshire and Derbyshire Regiment), to be Captain, with precedence as from August 4th, 1906 (dated Feb. 25th, 1910).

Attached to Units other than Medical Units.—Lieutenant Walter G. Paget to be Captain (dated Feb. 25th, 1910).

BRITISH RED CROSS SOCIETY.

In the Lord Mayor's Parlour of the Town Hall, Manchester, on April 22nd, a meeting was held for the purpose of forming a Manchester branch of the society.

Sir Frederick Treves delivered an address to the Westminster Branch of the British Red Cross Society at the Westminster City Hall on April 20th. The Duchess of Fife, who is the president of the branch, has nominated the Mayoress, Mrs. F. Harcourt Hillersdon, as a vice-president.

THE KING'S BIRTHDAY.

Notice is given in the *London Gazette* that the King's Birthday will be celebrated in London and at all Home Stations on Friday, June 24th next. At all other stations His Majesty's Birthday will be celebrated on Wednesday, Nov. 9th next.

COTTAGE HOSPITALS AT WIMBLEDON.—At the fortieth annual meeting of the North Wimbledon Cottage Hospital subscribers, held on April 23rd, Mr. J. F. Schwann, J.P., chairman of the committee, made an important statement as to the attitude of that institution in regard to the difficulty at present occupying much attention as to hospital matters in the borough. For years the council of the South Wimbledon Cottage Hospital has been urging an amalgamation with the North Wimbledon Cottage Hospital and the erection of a central hospital, the two present small hospitals being a considerable distance from the centre of the town. Many lively meetings have been held, but no agreement has been arrived at; and after being denied 16 sites through opposition from neighbours the council of the South Wimbledon institution has resolved to build a new hospital for 24 beds at The Rush, Merton, outside the borough, and still farther away from the middle of the town; while the North Wimbledon committee has resolved to extend the hospital at Copse Hill. Mr. Schwann on Saturday greatly deplored the decision of the South Wimbledon committee, and said he would have preferred that the funds and interests were combined and a large hospital built on the site at North Wimbledon, a receiving-room only being kept up in South Wimbledon. He reviewed the negotiations and said he had been strongly in favour of one hospital, but this was now out of the question. The report presented showed that 259 patients had been treated during the year, and there were 100 operations, the highest numbers yet recorded.

FEMALE HÆMOPHILIACS AND *DE NOVO* CASES OF HÆMOPHILIA.

To the Editor of THE LANCET.

SIR,—The new iatro-mathematical school comes as a wild nor'-easter to brace us into better mental health and habits. It was really delightful to hear Dr. Bulloch belabour the physicians at the Medical Society, and that I had myself to kiss the chastening rod added not a little to the enjoyment of the evening.

I would like to say a word or two on the question of female hæmophiliacs and the *de novo* cases. Dr. Bulloch thinks it extremely unlikely that any of the female cases are genuine. It is very difficult not to accept the following: A girl, aged 19, was admitted Nov. 16th, 1897, with epistaxis and purpura. The patient is one of three children, of whom one boy, aged 12, has always bled excessively when cut, has bled from the nose at intervals, and three weeks ago had purpura. The father had frequent epistaxis as a boy, and is now living and well; the mother is healthy and there are no bleeders known in her family. One of the father's brothers had frequent epistaxis; of his children, a son, aged 20, has had profuse epistaxis, and a few weeks ago he bled for two hours. Of course, such a history would not be regarded by Dr. Bulloch as very conclusive, and yet it shows a marked tendency to hæmorrhage. The girl herself has always bled freely when cut, when the teeth were drawn, or even when the gums were rubbed hard. A year ago she had soreness and swelling of both the shoulder-joints. She has had no menstrual irregularities. On Oct. 3rd she began to have epistaxis, which has continued at intervals ever since; at the same time she had bleeding from the gums. Hæmorrhages into the skin were noted about Nov. 1st. Her blood coagulation-time ranged from 10 to 15 minutes. In spite of all known methods of treatment the bleeding recurred at intervals, and successive crops of cutaneous hæmorrhage, and she died on Nov. 30th.

Was this a true hæmophiliac, or only an aggravated case of purpura hæmorrhagica in a family with marked tendency to epistaxis? The latter would no doubt be Dr. Bulloch's view. One has to recognise that purpura in severe forms may occur in several members of a family. I have notes of a case seen with Dr. F. H. Smith, a woman aged 63, whose mother died from purpura, and the patient's twin sister died from the same disease; there had been no other cases in the family.

There is a chronic purpura which must not be mistaken for hæmophilia. Miss E., aged 46, seen with Dr. Mary Sherwood, began to have epistaxis at her eleventh year. Every few months for the next five years she had severe attacks, almost always accompanied with crops of purpura. When about 26 years old the attacks of epistaxis ceased and she has only had two short attacks in the last 20 years. She does not think that for years she has ever been entirely free from spots of purpura, chiefly small scattered petechiæ. She bruises easily, and the slightest abrasion is followed by hæmorrhage, but she has never bled from the gums. I saw her in a severe attack of epistaxis, and the following day she had an enormous extravasation of blood involving the greater part of the skin of the front and outer side of the right arm.

As to the *de novo* origin, I mentioned in the discussion how important it is to look carefully into the family history, as the patients may deny knowledge of the peculiarity or they may not know the collateral history.

There is an Oxford bleeder, G. C., who has frequently been admitted to the infirmary, among whose ascendants it does not seem possible to trace any similar cases. He and his brother were bleeders from childhood—spontaneously, from slight cuts, and bruises. Both have been greatly troubled with the joint lesions. The brother died from tuberculosis at 26. The patient whom I saw the other day must be regarded as a bleeder. The tendency began about his second year; he has had frequent attacks of epistaxis, and on three occasions he nearly died from accidents—once when he "mashed" his finger in the door, the second occasion a cut on his right forefinger, and the third he accidentally scratched the roof of his mouth. He has also had three attacks of severe abdominal pain with vomiting of blood and melæna. He has been greatly troubled with swellings of the joints, which have come on at the time of the hæmorrhages, and the skin about them has been blood-stained. He is only just recovering from an attack in the ankles. He has small hæmorrhages into the muscles which leave little nodular thickenings, one of which is just disappearing from the left biceps. Three months ago he had to have a tooth taken out, and he bled at intervals for 12 days. The patient's mother died from tuberculosis; none of his brothers were bleeders; the maternal grandmother and grandfather not known, but the patient's father, an intelligent man, has never heard of any bleeders either in his wife's family or in his own.

I am, Sir, yours faithfully,

April 25th, 1910. WILLIAM OSLER.

A DANGEROUS DRY SHAMPOO.

To the Editor of THE LANCET.

SIR,—The danger of the dry shampoo with commercial carbon tetrachloride containing carbon bisulphide, thereby increasing its poisonous properties, has been so far established that any further fatal accident will result in a criminal prosecution. Before the inquiry into the above matter had been completed an immediate death in a hairdressing establishment resulted from the ignition of an inflammable mixture of air and vapour of petrol purchased from a neighbouring garage. It might have been expected that even if the use of such dangerous materials had not been stopped by legislation the public would have been sufficiently warned. One reads with surprise the following passage in a modern society paper:—

> The first thing to be done is to give it [the hair of a pretty girl] a dry shampoo; the best thing to use for this purpose being gasolene, which is not so very dangerous provided reasonable care is taken, which includes, of course, performing the operation in daylight. It is also a good plan to stop up the ears with cotton-wool, as some people are apt to find that *it* affects their hearing.

With regard to the above sentence, which has been copied exactly, it is desirable to point out that gasolene, properly so-called, sp. gr. at 15° C. = 0·66, cannot be purchased by the public, as its use for any general purpose has been strictly prohibited owing to its giving off an inflammable vapour even below ordinary room temperature, say 15° C., or 60° F. It must therefore be supposed that some other kind of petrol must be meant, which may be sold under a copied name; but there does not appear to be any guarantee that the flash-point of the article so supplied has been determined, nor that "reasonable care" would be taken even in daylight. A lighted match or even a cigarette end might, and probably would, produce a conflagration.

It is further presumed that the word "it" (the italics are those of the present writer) must refer to the gasolene and not to the cotton wool. If so, then the admission that the vapour of the gasolene affects the auditory apparatus, probably the membrana tympani, appears a sufficient condemnation; it would clearly require a very tightly-fitting plug of cotton wool to exclude all vapour. It may be pointed out that for cleansing hair, long or short, the old text ἄριστον μὲν ὕδωρ—"Water is the best"—still remains uncontroverted.

I am, Sir, yours faithfully,

April 25th, 1910. V. H. VELEY, F.R.S., D.Sc.

THE MIDWIVES BILL AND POOR-LAW RELIEF.

To the Editor of THE LANCET.

SIR,—A somewhat interesting discussion is being published in your columns on this subject. It might prove of interest to your readers and instructive to Mrs. Sidney Webb if I give two personal experiences of calls attended in the last year. Early in 1909 the Newbury board of guardians (owing to the difficulty found in getting practitioners to attend cases when summoned by a Central Midwives Board call) issued a notice to all legally qualified persons that the Board would pay in cases where such calls had been issued fees in accordance with the Poor-law scale. In August last, at 12 midnight, I received a C.M.B. call to Weston (six and a half miles), one of the villages under the control of the Newbury board.

This was sent to me as the nearest available practitioner. I attended and applied forceps under chloroform. Notice of the call was sent at the time to the guardians. The account was furnished in January, together with the detailed statement of notification of infectious disease certificates.

In January, 1910, I again received a C.M.B. call as the nearest practitioner to the same village for a case of violent hæmorrhage (miscarriage 5½ months). The midwife sent as death was imminent. This call was received at 2 A.M., and I had to motor cycle over frozen roads partially covered with water and the rain falling heavily. I cleared the uterus and attended the woman for over three weeks. I sent this call also to the Newbury board of guardians and claimed the fees. The clerk replied: 1. That the first claim was barred by statute (should have been sent in quarterly, although no date was named on the circular sent out); and, secondly, that the January claim was not for attendance at the delivery of a viable child. 2. That the guardians would see what they could do if I could prove to them that I had taken reasonable steps to secure the fee from the person attended. The women were in both cases the wives of labourers earning one 12*s.*, the other 13*s.* a week. I should not dream of attending such persons in my own neighbourhood on credit unless as district medical officer under a guardians order, and am certainly not going to dun such persons for fees which the guardians of that district had promised to pay to any practitioner so called. For the future some other and younger medical man can attend these calls in the district of the Newbury board of guardians.

The nett result of the matter is that I have had pounds of out-of-pocket expenses and hours of time taken up attending persons that I never voluntarily undertook to attend, owing to the joint action of the Central Midwives Board and the Newbury board of guardians, and have not received one penny piece. To paraphrase the last words of Mrs. Sidney Webb's letter, "Why should doctors be treated differently from other men?"—I am, Sir, yours faithfully,

CHARLES S. PATTERSON, M.B. Edin., M.R.C.S. Eng.,
Medical Officer, Lambourn District, Hungerford Board of Guardians.

Lambourn, Berkshire, April 22nd, 1910.

THE JOHN HERBERT WELLS FUND.

To the Editor of THE LANCET.

SIR,—Referring to the appeal on behalf of the widow and children of the late Dr. J. H. Wells, who died in the course of research work, we write to say that the sum actually received in response to the appeal amounted to £4760, which has been invested by the direction of the committee in the names of the Right Honourable the Earl of Dalhousie, Sir Almroth E. Wright, M.D., F.R.S., Leonard Colebrook, M.B., B.S., Julian G. Lousada, and John Matthews, M.B., B.C., who hold it under a deed of trust on behalf of the beneficiaries.

We are, Sir, yours faithfully,

DALHOUSIE
JULIAN G. LOUSADA } Honorary Secretaries, the Wells Appeal Fund.

Old Broad-street, E.C., April 25th, 1910.

CÆSAREAN SECTION IN PLACENTA PRÆVIA.

To the Editor of THE LANCET.

SIR,—The following statistics, which did not arrive in time to utilise in the discussion at the meeting of the Obstetrical and Gynæcological Section of the Royal Society of Medicine on April 14th, may be of interest.

Dr. Thrès, from Professor Bumm's clinic in Berlin, records from the year 1904 to 1909, 179 cases of placenta prævia. The total maternal mortality 5 (2·85 per cent.), 94 of the fœtus (52 per cent.). 15 vaginal Cæsarean sections were performed, with 1 maternal death (6·6 per cent.). Mortality of the fœtus 7 (46·6 per cent.). Professor Dimitri de Ott, from the Imperial Institute of Obstetrics and Gynæcology, St. Petersburg: During 18 years there were 111 cases of placenta prævia, with a total maternal mortality of 2·51 per cent., and of the fœtus 71 per cent. No Cæsarean section has been performed. From Sir Halliday Croom I learn that no Cæsarean section for placenta prævia has been performed to his knowledge in Edinburgh, and Dr. Munro Kerr (Glasgow Maternity) says that the only case in which he performed Cæsarean section for placenta prævia was the successful one already reported.[1] He is "convinced that the operation has a place in certain well-chosen cases, but these are very few and far between.

I am, Sir, yours faithfully,

April 23rd, 1910. H. MACNAUGHTON-JONES.

FOXWELL MEMORIAL.

To the Editor of THE LANCET.

SIR,—We ask permission to call attention in your columns to a fund which has been opened with the object of perpetuating the memory of our late friend and colleague Dr. Arthur Foxwell, whose untimely death by accident last year was, and still is, deeply deplored. It has been decided that the memorial shall take the twofold form of a mural tablet to be affixed within the Queen's Hospital, and of an annual prize for a clinical essay open to residents of several Birmingham hospitals.

Personal friends, colleagues, and past house physicians of Dr. Foxwell have subscribed for these purposes about £200, of which sum £150 is available for endowment of the prize. If there are other friends and former associates of Dr. Foxwell who would wish to contribute to this memorial we beg to intimate to them that the fund is not closed, and that we shall be grateful for any further subscriptions.

We are, Sir, yours faithfully,

J. T. J. MORRISON,
Chairman of the Medical Committee, Queen's Hospital.
O. J. KAUFFMANN,
22, Broad-street, Birmingham.
A. W. NUTHALL,
89, Cornwall-street, Birmingham.
W. F. HASLAM,
54, Newhall-street, Birmingham.
} Treasurers of the Fund.

Birmingham, April 25th, 1910.

THE FAR EASTERN ASSOCIATION OF TROPICAL MEDICINE.

(FROM A SPECIAL CORRESPONDENT.)

FIRST BIENNIAL MEETING.

THE first biennial meeting of the Far Eastern Association of Tropical Medicine was opened on Saturday, March 5th, in the Administration Building of the Philippine General Hospital, Manila, by an address of welcome from the Hon. GREGORIO ARANETA, Minister of Justice, in the unfortunate absence, through indisposition, of His Excellency Vice-Governor N. W. Gilbert. An address on behalf of the city of Manila was then given by the Hon. FELIX M. ROXAS, President of the Municipal Board, after which the President of the Association, Dr. PAUL C. FREER, delivered his opening address on "The Tropical Sunlight." In the evening a reception and dance to the foreign delegates were given at the University Club.

On the following day a visit to the Naval Hospital at Cañacao, Cavite, by invitation of the Medical Corps, United States Navy, was made. Some 30 members were present and the hospital was thoroughly inspected, every courtesy being extended to the visiting members by Surgeon E. R. Stitt and the assistant surgeons. The hospital is an excellent, up-to-date building, with every modern convenience, and is built of reinforced concrete, all the windows being protected from mosquitoes by wire netting. There is quite a large out-patient department carried on by this hospital amongst the native Filipino and others in the surrounding district.

On Monday, March 7th, the scientific work commenced at 9 A.M. in the Administration Building of the New General Hospital, which is almost finished but not yet occupied, and was built to replace the present Civil Hospital, which is an old Spanish building in the central part of the town. It is situated to the north of the Bureau of Science and within 200 yards of it. In accordance with the prevailing practice it is built entirely of reinforced concrete. There were excellent exhibits of foodstuffs and medicinal plants, as well as pathological and zoological specimens. The snakes of the Philippines were to be seen on the ground floor.

[1] Transactions of the Royal Society of Medicine, vol. iii., p. 1.

Major W. P. CHAMBERLAIN of the United States Army read an interesting paper on Statistical Studies of Uncinariasis among White Men in the Philippines. He showed how much more prevalent the uncinaria Americana (necator Americanus) was than the ankylostoma duodenale, and how, in all probability, it was introduced to the Philippines by the American troops.—In the discussion which ensued Dr. J. M. ATKINSON (Hong-Kong) asked in what part of the United States this hookworm was prevalent, and whether a medical examination, more especially with regard to the possible presence of this parasite, was not now made before the recruits left the United States, as it was a serious matter introducing a parasite from the West to the East, especially when it found a suitable habitat in the intestines of the Filipino natives. He also inquired whether there was no evidence of the presence of the parasite during the Spanish occupation of the islands.—Major CHAMBERLAIN, in his reply, stated that this examination is now carried on, but there were only scanty records of any parasitic prevalence in the writings of the Spanish doctors.

The next paper, on Unidentified Larvæ of some Dipterous Insect Developing in the Deep Urethra and Bladder, was read (for Assistant-Surgeon G. P. TRIBLE) by Surgeon E. R. STITT, United States Navy.

Mr. C. S. BANKS, of the Biological Department of the Manila Bureau of Science, then read an interesting paper on the Rôle of Arthropoda in Man's Life in the Tropics. A discussion followed.

The next paper, Flies and Fleas as Factors in the Dissemination of Disease, by Dr. J. S. PURDY (Auckland, New Zealand) was read by Dr. CLARK, the secretary of the association.

The last paper was on the Treatment of Trypanosomiasis by Dr. R. P. STRONG and Dr. O. TEAGUE, Biological Laboratory, Bureau of Science. (See Fig. 1.) It demonstrated how the administration of arseno-phenylglycin, which had been kindly supplied from Berlin (Professor Ehrlich's laboratory), had caused the disappearance of the trypanosomes in the blood of monkeys suffering from surra. Elaborate tables were shown proving that in those animals which had been inoculated with surra a dose proportionate to the body weight of the animals had practically cured them of this disease. The results of similar experiments with horses were given; although in a few cases improvement had occurred the results in horses were not so conclusive as were those in monkeys.

In the afternoon a visit to the Germinal Tobacco Company was made, the director, Dr. Batista de Leon, one of the members of the Association, courteously acting as guide. One thousand nine hundred hands, chiefly Filipinos, are employed, and the death-rate amongst the employés is only about 2 per 1000. Seven and a half million cigarettes and 275,000 cigars are daily turned out by this factory, figures which are certainly staggering. Some 50 of the members with most of the foreign delegates were present, many being accompanied by their wives. From 5 to 7 P.M. a reception was given by Mrs. Higgins at Caloocan, at which many of the delegates attended. The grounds were beautifully illuminated, and the orchids and palms were much admired.

The third session was opened on Tuesday, March 8th, by "An Historical Survey of Plague in Hong-Kong since its Outbreak in 1894, with an Account of the Measures which had been taken in Dealing with It," by Dr. J. M. ATKINSON, principal civil medical officer, Hong-Kong.—This was followed by a paper from Dr. F. W. CLARK, medical officer of health, Hong-Kong, detailing the present procedure *re* plague measures in Hong-Kong.—A discussion followed, in which Dr. H. C. HIGHET (Siam), Dr. A. CASTELLANI (Ceylon), Mr. G. E. BROOKE (Singapore), and Dr. R. P. STRONG took part.

A paper on the Present Position of the Leper in view of the Resolutions passed at the International Conference on Leprosy at Bergen, 1909, was read on behalf of Sir ALLAN PERRY, principal medical officer of Ceylon, by Dr. FRANCIS CLARK.—At the conclusion of the paper Dr. ATKINSON suggested the formation of committees to consider during the present session what practical measures could be advanced *re* leprosy, plague and quarantine, and beri-beri. He pointed out that if this were done much practical good would result. Never before in the East had there been such a gathering of delegates, practically from every country east of Suez, there being delegates from Ceylon, India, Federated Malay States, the Straits Settlements, Netherlands Indies, Siam, Hong-Kong, Tsingtau (German), Hankow (China), and Japan, and it was a pity to lose such an opportunity.—Dr. P. HIGHET seconded, and it was agreed to appoint such committees, the nomination being left to the President.

Later committees were appointed to consider and report on, in addition, tuberculosis and the opium question.

Mr. M. T. CLEGG, of the Biological Laboratory, Bureau of Science, read a paper on Leprosy, and a demonstration was given by Major E. R. WHITMORE, United States Army, of the cultivation of the leprosy bacillus in artificial media. This, which has baffled bacteriologists for years, has been accomplished by Mr. Clegg. He has grown it in symbiosis with amœbæ, and the technique, which he explained, will be fully described in the Transactions. He first grows the amœbæ in gelatin cultures, then introduces the lepra bacillus, kills off the amœbæ, and obtains a growth of the lepra bacillus on gelatin. Dr. SHIBAYAMA (Japan) also demonstrated leprosy in living rats and guinea-pigs.

Dr. A. W. SELLARDS, of the Bureau of Science, read a paper on the Treatment of Asiatic Cholera.

Dr. A. F. COCA'S (Bureau of Science) Treatment of Cancer by a vaccine prepared from the cancer growth itself was described by Dr. P. K. GILMAN. The tumour tissue immediately after excision is comminuted as far as possible with scissors, and passed ten times through a vaccine grinder which has been sterilised by successive rinsing with pure carbolic acid, absolute alcohol, and sterile salt solution. After the first passage through the grinder an equal volume of sterile salt solution is added. By this thorough grinding of the tissue practically the tumour cells are completely broken up, so that the decanted fluid contains all the protoplasmic and nuclear substances of these cells. In order to get rid of the threads of fibrous tissue the thick creamy fluid is centrifuged at a high speed for three minutes and decanted. A cubic centimetre of 5 per cent. carbolic acid is then added to every 10 cubic centimetres of fluid. Injection is made preferably within six hours after addition of carbolic acid, otherwise the fluid must be kept in cold storage. Notes of several cases in which it has been used with success were read. This investigation is still further being carried on by Dr. Coca.

At 1.30 P.M. a luncheon was given by the medical officers at the Division Hospital, United States Army. Afterwards a visit was paid to the wards, where several interesting cases of tropical disease were shown, particularly some cases of sprue and malarial fever. A series of six cases of skin reaction in suspected tuberculosis were shown.

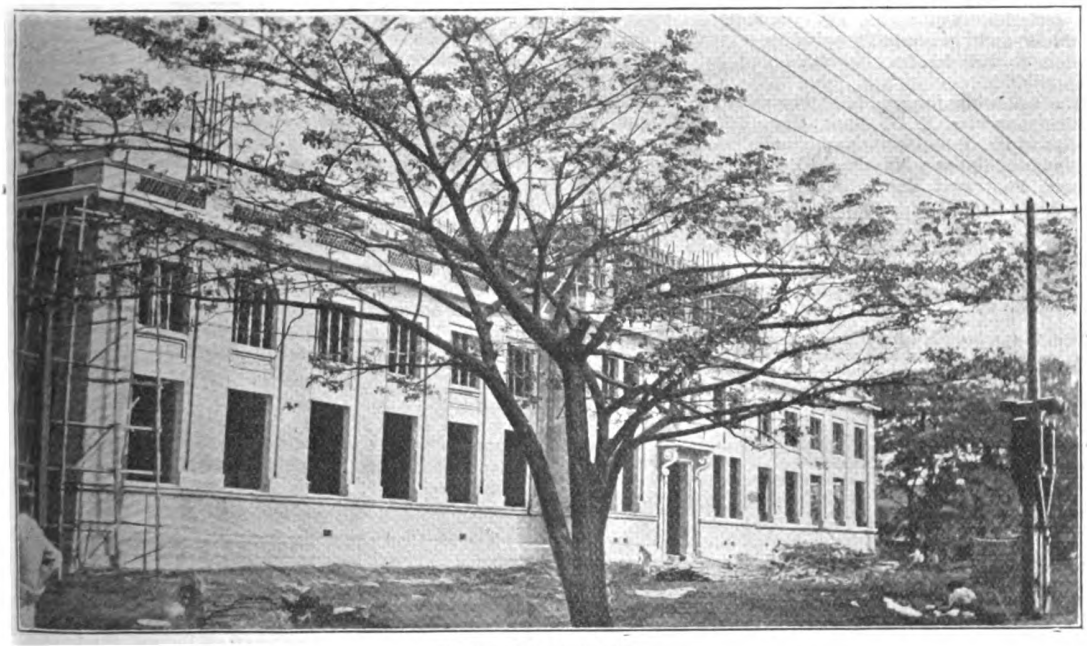
On Wednesday, March 9th, various papers were read, including one by Major A. HOOTON, I.M.S., on Litholapaxy, detailing his experiences of this operation in India.

In the afternoon, between 3 P.M. and 5 P.M., visits were made to the Medical College (Fig. 2), the San Lazaro Hospital, and the health stations in charge of the Bureau of Health, when Dr. V. G. HEISER explained the methods in use of scavenging and removal of night soil. At 9 P.M. there was a reception at the English Club, San Marcelino, followed by a dance.

On Thursday, March 10th, the general subject for discussion was Fever in the Tropics, although the meeting opened with an interesting address delivered by Mr. G. E. BROOKE, health officer of Singapore, on Trachoma. An animated discussion ensued. Other papers dealing with malaria followed, together with one on typhoid fever.

In the afternoon a visit to Fort McKinley, by invitation of the Medical Corps, United States Army, was made. The Post hospital was visited, and a company of the Army Medical Corps with field hospital equipment was inspected; and at 9 P.M. a reception was given to the delegates by Dr. and Mrs. Freer.

On Friday, March 11th, the session was devoted to dysentery and beri-beri. This was a most interesting morning.



Dr. H. FRASER (Federated States), Dr. J. DE HAAN (Netherlands Indies), Dr. H. C. HIGHET (Siam), and Dr. Y. K. OHNO (Manila), all working on the same subject, unbeknown to each other, practically came to the same conclusion—viz., that a most important, if not *the* most important, factor in the etiology of beri-beri was the consumption of white (polished) rice as the staple article of diet. Dr. Fraser's experiments at the Federated States were ably and succinctly given and will be fully detailed in the printed Transactions. Briefly stated, it is the deficiency of the fat and proteid layer of the rice grain which is removed during the process of polishing that causes

FIG. 1.

Bureau of Science, Manila.

FIG. 2.

Medical College, Manila.

or appears to cause beri-beri. In this layer there is a certain percentage of P_2O_5, the deficiency of which may be the important factor.[1] At any rate, it is the eating of rice impoverished by polishing which seems to produce beri-beri.

At 8 P.M. there was a subscription dinner at the Army and Navy Club to the delegates under the chairmanship of His Excellency NEWTON W. GILBERT, Vice-Governor of the Philippine Islands.

On Saturday, March 12th, the following papers were read: Dr. G. SHIBAYAMA: Beri-beri as Occurring in Japan. Dr. CASTELLANI: Various Subjects in Tropical Medicine. Major HOOTON: Mycetoma. Surgeon E. R. STITT: On a Method of Making Blood Counts in Wet Preparations. Three papers on tuberculosis followed.

In the evening the foreign delegates, accompanied by some 20 members of the association, left for Baguio, the hill station and health resort of Manila, at 10 P.M. Here Sunday was spent in visiting hospitals, civil and military, and generally exploring Baguio, which is situated some 5400 feet above the sea level and is an excellent hill station very similar in a way to Simla. There is a plateau some 30 miles in extent, which is becoming gradually covered with bungalows. There is an excellent country club with a golf course, a polo ground, baseball ground, and practically all the accessories of a delightful hill station. The temperature, which was 86° F. in Manila, was only 62° at Baguio.

The eighth session on Monday, March 14th, was devoted to climate, hygiene and sanitation. Six papers were down for discussion but only two were read—namely, one by Dr. V. G. HEISER, of the Bureau of Health, on Problems which Confront the Bureau of Health, and another by Captain J. M. PHALEN, of the United States Army, on an Experiment with Orange-red Underwear in the Tropics. An interesting discussion followed on both these papers. The remaining papers were taken as read.

This the first meeting of the Far Eastern Association of Tropical Medicine was successfully brought to a conclusion by the business meeting, which followed an interesting paper by His Excellency Mr. DEAN WORCESTER, Minister of the Interior, on Baguio as a Health Resort. At this business meeting an invitation from the Governor of Hong-Kong was submitted that the second meeting be held at Hong-Kong in 1912; this was accepted with acclamation, and Dr. J. M. Atkinson was appointed president, with Dr. F. W. Clark honorary secretary and treasurer.

The meeting was closed with a vote of thanks to all the societies, institutions, and residents for their extreme kindness and generous hospitality extended during the session to the foreign delegates and to the association generally.

The following foreign delegates were present: Dr. J. M. Atkinson and Dr. F. W. Clark, Hong-Kong; Captain H. M. Neeb and Dr. J. de Haan, Netherlands Indies; Dr. Gorusaku Shibayama, Japan; Mr. G. E. Brooke, Singapore; Dr. H. Fraser, Federated Malay States; Dr. H. C. Highet, Siam; Dr. Aldo Castellani, Ceylon; Dr. Staby, Tsingtau; Dr. Beebee, Hankow, China. Major A. Hooton, I.M.S., and Dr. M. H. Fulton, Canton, were also present.

The Association passed the following resolutions dealing with various diseases, quarantine, and opium:—

Beri-beri.

That in the opinion of this Association sufficient evidence has now been produced in support of the view that beri-beri is associated with the continuous consumption of white (polished) rice, as the staple article of diet, and the Association accordingly desires to bring this matter to the notice of the various Governments concerned.

Leprosy.

That: 1. Leprosy is to be regarded as a dangerous communicable disease. 2. Compulsory notification of all cases of leprosy to the authorities is essential. 3. Compulsory segregation of all cases of leprosy is necessary and preferably in special colonies constructed for the purpose. 4. The entrance of aliens afflicted with leprosy into a country must be prohibited.

Plague.

In our opinion the only practical measure concerning plague that we can recommend is the advisability of each country represented agreeing to notify to other countries the occurrence of cases of plague within their borders, the first case by telegram and afterwards by weekly returns.

Tuberculosis.

That the Far Eastern Association of Tropical Medicine should use its influence to cause the formation of a national anti-tuberculous society in each political entity represented in the Far Eastern Association of Tropical Medicine. These societies to be formed along the lines of existing anti-tuberculous societies in other parts of the world, yet revised to facilitate the work under local conditions.

Quarantine.

That the Far Eastern Association of Tropical Medicine, appreciating the benefit which would accrue from concerted sanitary action on the part of Eastern Governments, be empowered officially to approach the following Governments—namely, Philippine Islands, Japan, Hong-Kong, French Indo-China, Siam, Netherlands-India, Straits Settlements and Ceylon, with the view, if possible, of obtaining their official support on the following lines:—1. To have a common standard for the term "epidemic" when making reports to, or imposing quarantine against, each other. We suggest the following definition for consideration:—"Plague, cholera, small-pox, or yellow fever shall be considered to be epidemic when, after the first telegraphic report of its occurrence, any weekly report thereafter shall show the occurrence of an average daily number of three cases." 2. To agree to notify each other's territories as infected only when the infectious disease shall have assumed epidemic proportions as defined above; and automatically to withdraw such notification when the average number of cases for three successive weeks has fallen below the *status epidemicus* as above defined. 3. To circulate weekly returns of plague, cholera, small-pox or yellow fever amongst each other, and also a telegraphic report on the first occurrence of any of these diseases, in a clean port or territory. 4. To insist on a bill of health being carried by all ships, leaving a country declared to be infected, which intend to proceed to the port of another signatory; such bills of health to include a return of infectious disease for the previous 48 hours. 5. To report by telegram to the country concerned, the departure of an infected or suspected ship (as defined by the Paris Convention) which may intend to proceed to any port in the territories of another signatory; and to endorse the bill of health of the said infected or suspected ship with a full account of measures taken to disinfect or otherwise deal with the said vessel.

Opium.

The committee appointed to consider the opium question regret that the time at their disposal precludes the possibility of giving the subject adequate consideration. They have reviewed the work done and the resolutions agreed on by the International Opium Commission, Shanghai, 1909. With these resolutions the Committee are in agreement, but it is to be regretted that the paucity of medical commissioners prevented the question being dealt with fully in its medical aspects. Any measures which are introduced for the control of opium must be adequate to guard against the danger of secret remedies containing opium and opium derivatives being substituted. They would suggest that the delegates from the various countries represented at this Conference should be asked to arrange that the regulations controlling the sale and use of opium in their respective countries, as well as any observations they may care to make on this subject, be submitted to the next meeting of this Association in 1912.

[1] THE LANCET, March 12th, 1910, p. 733.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENT.)

University of Bristol.

DRAFT ordinances have recently been approved by the University Council which contain important provisions for supplementing university teaching in professional or technical directions by associating with it institutions in which teaching of a specialised character is given or in which facilities for research in special directions are afforded. For university purposes such institutions will be treated as part of the University itself. Provision is also made in the ordinance for affiliation of other educational institutions, attendance in which may be accepted in lieu of attendance in classes within the University itself. Professor A. P. Chattock has resigned the professorship of physics, held by him for some years; the Council accepted his resignation with expressions of deep regret.

Dinner to Mr. L. M. Griffiths.

The Clifton Shakspere Society on Saturday, April 23rd gave a dinner in honour of Mr. L. M. Griffiths, who has resigned his offices of honorary secretary and honorary librarian to the society after 34 years' service. The society's excellent library is now housed within the University premises.

The Medical Dramatic Entertainment.

The Medical Dramatic Society of the University of Bristol gave its annual entertainment at All Saints' Hall, Clifton, the play performed being *An American Citizen*, by Madeleine Lucette Ryley. The leading parts were admirably played by Mrs. P. A. Opie and Miss Duncan-Lees, while Mr. R. Dacre scored a great success as Simms, the imperturbable valet. The hall was filled on each of the five nights, and it is confidently anticipated that a substantial sum will be realised. The proceeds are to be devoted to the help of the University Clubs Union.

April 26th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Changes in the Surgical Staff of the Royal Infirmary.

Mr. F. A. Southam, in view of the approaching expiration of his term of office as honorary surgeon at the infirmary, has resigned the professorship of clinical surgery at the University of Manchester. Mr. Southam followed Mr. Walter Whitehead in 1900, and has held the position with great advantage and benefit to the Medical School and students. He is to be succeeded by Mr. William Thorburn, M.D., B.S. Lond., F.R.C.S. Eng., who has long been connected with the Owens College, the University, and the Manchester Royal Infirmary, first as a student and then as a very able member of the teaching staff. Mr. Thorburn was a distinguished student, and his subsequent career has fully borne out the promise of his early days. He became assistant surgeon to the infirmary in 1889 and surgeon in 1899. Graduating in medicine at the University of London, he obtained the scholarship and gold medal in medicine, the gold medal in obstetric medicine, and also the gold medal in surgery. In 1891 he obtained the Jacksonian prize of the Royal College of Surgeons of England, and in 1894 was appointed Hunterian professor of surgery and pathology. He is also an examiner in the University of London.

Open-air Schools.

It is satisfactory to know that the experiment of open-air schools for delicate children seems to be generally a success. One of the latest to come under notice is that of Halifax, where during last summer 130 children were admitted to the open-air school at Bemerside suffering from one or other of the following formidable list of ailments: anæmia, enlarged glands, bronchitis, phthisis, chorea, and rickets. The head mistress reports that the children were generally improved, and some so much so as scarcely to be recognised for the delicate and puny little people who arrived on the first morning. They were happier, better tempered, more cheerful, and their intelligence was much improved. It would be well if these experiments were carried out more extensively, of course with judgment, for the results so far are certainly promising.

Royal Albert Institution.

The annual joint meeting of the Manchester committees of the Royal Albert Institution, Lancaster, was held in Manchester on April 19th. The secretary reported that the Manchester Ladies' Association had so far collected over £317 for the current financial year. The alteration of the title of the institution will be noticed. It was felt that the name Royal Albert Asylum was more likely to be confused with the rate-supported lunatic asylums than when it was called an institution. The Manchester and Salford district is a wide one, including the towns of Bolton, Burnley, Bury, Leigh, Oldham, and Wigan, and it is considerably indebted to the institution for maintaining the 155 local patients now in the institution. An appeal has therefore been made to cover this indebtedness. There are 686 patients at present in the institution, 283 of them from Lancashire, while there are many urgent applications for free admission by election. There is to be an election next month, with 83 candidates for 40 vacancies, while Lancashire has 28 applicants for 16 places. These figures tell little or nothing of the hope, the anxiety, and distress involved in each single case. The appeal for help is fully justified, for the cause is good and must call forth sympathy from all.

Mr. Thomas Windsor, M.R.C.S. Eng., L.S.A.

To the junior members of the medical profession in Manchester the name Tom Windsor, as his more familiar friends called him, is little known, or only known as belonging to a past era, for he retired from practice many years ago. But during a considerable part of the latter half of the nineteenth century he had a great and deserved reputation as an ophthalmic surgeon. He was born in 1831, qualified in 1853-54, and died at Great Budworth, Cheshire, on April 13th. He was the son of a well-known and highly esteemed general practitioner, Mr. John Windsor, but struck out a line of his own, soon becoming surgeon to the Royal Hospital, Salford, and to the Manchester Eye Hospital, being also, for a time, surgeon to the Manchester Southern Hospital for Women and Children. Later he became ophthalmic surgeon to the Royal Infirmary and lecturer on ophthalmology at the Owens College, before its absorption into the University of Manchester. In addition to the clinical position which these appointments, successfully filled, prove him to have occupied, he was a man of great culture. His knowledge of medical literature, both ancient and modern, was, without exaggeration, phenomenal, and he was known among his friends as a most ardent lover of books. This it was that led him to devote his leisure hours for over 20 years to the building up, arranging, and cataloguing of the Manchester Medical Society's library, one of the finest in the country. For some years he edited the *Ophthalmic Review* and was the author of the New Sydenham Society's Reports on Surgery for 1862–64 and Report on Ophthalmic Medicine and Surgery 1865–66. He was not a great traveller, but made on one occasion what was considered in those days rather an adventurous journey to Russia, seeing, among other things, the famous fair at Nijni Novgorod.

April 26th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Educational Treatment of Consumptives.

THE health committee, in a report to be presented to the city council on May 3rd, states that experience in the working of Salterley Grange Sanatorium has forced upon it he desirability of making provision for the treatment of more advanced cases of consumption than are eligible for the sanatorium. Experience in selecting patients for the sanatorium has shown that the majority of applicants have passed the first stage of the disease. Many, however, would derive great benefit from a short course of treatment, and their infectivity would be reduced. The committee feels that facilities should be provided for a short period of educational and recuperative treatment for patients of this class. The small-pox hospital at Little Bromwich has been unoccupied for five years, and at small cost it could be made suitable for consumptives. It is proposed to adapt two large pavilions by certain internal alterations and the erection of a covered verandah. Two shelters will also be required in the grounds. The total cost of the alterations is estimated at £1200. It is intended that the average treatment shall last six weeks, thus allowing 400 cases to be received during the year. The main feature in connexion with the treatment will be the practical instruction of the patients in the value of fresh air and in the regulation of their own lives, so that they may learn how best to combat the disease and prevent infection of others. The staff would include a visiting physician skilled in the treatment of consumption, a resident medical officer, matron, nurses, and so on. The cost of maintenance is estimated at about £2500 per annum.

Proposed Taylor Memorial Home.

A project is on foot for the establishment of a home for incurables in connexion with the Birmingham and Midland Hospital for Women. A statement signed by Dr. Ann E. Clark, Mr. Christopher Martin, Mr. J. Furneaux Jordan, Mr. F. Edge, Dr. Mary D. Sturge, and Mr. J. T. Hewetson, the members of the honorary staff, sets forth the need for the proposed home. It points out that at the Women's Hospital patients suffering from internal malignant disease can in many instances be practically restored to health by operation; but, on the other hand, there are cases in which the malady is too advanced for successful treatment, and only a few weeks or months of life remain to such women. Where and how are they to pass this period of suffering? They are too ill to live alone, and if relatives exist, these usually consist of persons with young families dwelling in crowded houses entirely unfit for the reception of cases of hopeless disease. The average workhouse infirmary is not the place to be suggested to many of these deserving and self-respecting poor. An influential committee has been formed to advance the scheme, and it is proposed to begin in a very small way with a simple nursing home near the hospital containing six or eight beds. The cost of maintenance is estimated at £300, the friends of patients being expected to contribute a small sum weekly when able to do so. The

suggestion is made that the home should be called "The Taylor Memorial Home," in recognition and commemoration of the 24 years' valued and self-sacrificing services rendered the hospital by the late Professor Taylor. Among the promises of donations received is one of £500 from Mrs. W. A. Cadbury and another of £105 from Mrs. Christopher James.

April 26th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

A Highland Medical Officer's Heroism.

A LOCHBROOM correspondent of the *Scotsman* writes: "Dr. Gunn, medical officer of the parish of Lochbroom, in response to a call to a keeper's house some twenty-five miles distant, left in the early morning cycling. Before he had gone far a gale sprang up, which gradually increased to a hurricane. Sheets of rain came down in the valleys. On the hill-tops and mountain ridges snow fell, and sweeping downwards melted into coldest sleet. A stormier day has seldom been experienced in the district. The keeper's house was reached after a trying journey. But that was not all. Dr. Gunn left behind him a patient, who, if not visited that night, would be in imminent danger. To cycle back or, indeed, to cycle at all was quite out of the question, but to return somehow was a necessity of which Dr. Gunn had never lost sight. By this time the day had worn into evening. To walk back by the road would mean not reaching home till well into the following morning. To take a short cut over the hills was the only possible course. Securing, therefore, a trustworthy guide, Dr. Gunn walked out into the late evening and on to the mountain side and over it, and through the darkest night and wildest he walked or scrambled somehow over a famous spur of Benmore Coigach called the Coigach Rock. The mountain is based on the rock in question, which rises sheer for many hundred feet out of the sea. There is no path, and so dangerous was the route taken by the doctor and his guide in the night that only men of nerve would dare try it in daylight. With almost superhuman strength the worthy doctor pushed forward and arrived at the house of his suffering patient in a state verging on collapse, but rewarded by the sense of having done his duty and saved a life." We congratulate Dr. Andrew Rugg Gunn on a veritably heroic act.

Tuberculosis in Glasgow.

The Glasgow and District Societies' Committee for the Suppression of Tuberculosis, which has been in existence for two years, has been reconstituted on a wider basis, and will henceforth be known as the Glasgow and District Societies' Council of Public Health. The organisation was originally a joint committee of the Trades' Council and the Friendly Societies' Federation, and after some time its ranks were increased by the inclusion of delegates from coöperative societies. At the last meeting there were represented 28 trade unions, 11 ward committees, 10 coöperative societies, and 5 friendly societies. A resolution was adopted calling upon the corporation to provide dispensaries in all working-class parts of the city where advice, appliances, and other assistance would be given free of charge and without stigma to all persons suffering from tuberculosis who lived within the city boundaries. Another motion was also approved which demanded that the corporation should go further and provide hospitals for the treatment and isolation of tuberculous patients, the only tuberculous cases at present dealt with in hospitals in the city being those passed by the parish council.

Clinical Laboratory for Western Infirmary, Glasgow.

At the Dean of Guild Court the directors of the Western Infirmary have been granted warrant to erect a block of buildings in the infirmary grounds. When completed the new block, which is estimated to cost £5000, will be used as a clinical laboratory.

Post-graduate Course at Royal Infirmary, Glasgow.

The classes in connexion with the post-graduate course at the Royal Infirmary, Glasgow, will commence on May 2nd. Anyone desirous of attending any of the classes may obtain information by applying to Dr. J. M. Thom, superintendent of the infirmary.

Extension of Stirling Infirmary.

The extension of the Stirling Royal Infirmary has been discussed for some time, but the lack of accommodation has now become so evident that the directors feel that building operations can no longer be delayed. It has now been resolved to proceed with one part of the work in the meantime—that of a new west wing, which will provide convenient and commodious accommodation for dispensary out-patients and also for the staff. The cost of the new wing will be about £4300.

April 26th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Post-Graduate Classes in the University of Dublin.

TRINITY College, Dublin, the first medical school in Ireland to start systematic lectures and demonstrations for qualified practitioners, has issued its annual syllabus of post-graduate classes. As for the past two years, there will be a summer and an autumn course. The former will begin on June 6th and the latter on Sept. 19th. The duration of each course will be three weeks. Instruction will be given in medicine, surgery, gynæcology, diseases of the eye, ear, throat, nose, and skin, and also in anatomy, physiology, urology, and radiology. The classes are essentially practical and are specially adapted to the requirements of the general practitioner. One advantage of having two sessions each year is that the classes are more limited in numbers so that each member has an opportunity of personally examining every case which is demonstrated. During the operative surgery course a considerable number of operations is performed on the cadaver by each member of the class. The inaugural lecture will for this year be given by Mr. B. G. A. Moynihan. The social side of the class has not been forgotten. Members, whether graduates of the University of Dublin or not, can obtain, if they so desire, completely furnished rooms in College, and can dine on commons. Particulars of fees and a prospectus may be obtained on application to the honorary secretary, Dr. A. R. Parsons, 27, Lower Fitzwilliam-street, Dublin.

Belfast Ophthalmic Institution.

At the annual meeting of the supporters of this Belfast charity, held on April 19th, the Lord Mayor presiding, it was reported that there were in the past year 145 intern and 1370 extern eye, and 776 extern ear, nose, and throat cases. The extern department, thanks to the help of various friends, has been renovated, there being now three main and three smaller rooms, besides additional dark rooms, and a small extern theatre for the carrying out of minor operations and dressings. These changes cost £425. Financially there is a debit balance of £25. The income was £300, which very nearly met the current expenditure of the institution.

Newry Water-supply.

Mr. J. N. Richardson, D.L., has not only paid the expert who made a report as to the existing defects in the supply of water from Camlough mountain to Newry, but he has also offered to undertake, at his own expense, to carry out these changes. At a meeting of the Newry urban council, held on April 19th, Mr. Richardson's act was referred to in the warmest terms of praise.

County Antrim Infirmary.

It was unanimously resolved at a public meeting of the inhabitants of Lisburn, held on April 18th, to promote a bazaar to raise the cost of an electrical installation for the County Antrim Infirmary in Lisburn. It is estimated that the cost will be about £1000.

Ulster Medical Society.

The eighth meeting of the session was held on Thursday, April 21st, in the Physiological Department of the Queen's University of Belfast, Dr. J. J. Austin, the President, being in the chair. Professor T. H. Milroy read a paper on the Experimental Study of Mental Fatigue. Dr. J. A. Milroy gave a communication on the Oxygen Capacity of the Blood. In the Pathological Laboratory Dr. W. J. Wilson gave a short paper on Carbon Monoxide Poisoning. Specimens of

glossina palpalis, presented to the Hygiene Museum, were shown by Surgeon A. McCloy, R.N., while Dr. J. A. Sinton showed some preparations of trypanosomes and spirochætæ. In the Anatomy Department Mr. P. T. Crymble gave a lantern demonstration of (*a*) the suspensory muscle of Treitz; and (*b*) the blood-supply and position of the pelvic colon. He also showed specimens of (*a*) diverticulum of the duodenum; and (*b*) preparations demonstrating the anatomy of lumbar puncture. Dr. J. S. Dickey exhibited drawings, slides, and casts illustrating the anatomy of the apex of the lung. Professor J. Symington, Dr. J. Rankin, and Mr. J. Holmes showed anatomical specimens.

Superstition in Ulster.

At an inquest held at Banbridge, County Down, on April 23rd, on the death of a young woman, aged 22 years, it came out in evidence that her father got a "cure" for her disease—which was erysipelas—consisting of a bit of butter, which he took to a "charmer" in Tandragee, who gave it back to him, and with it he treated her until, finding her getting worse, he called in Dr. W. N. McWilliam of Banbridge. The doctor said the effect of the charm was purely negative; had the girl been put under proper medical treatment there was a strong probability that she would have been saved. The jury returned a verdict in accordance with the medical evidence, but disagreed as to adding any rider to their verdict.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Medical Students in France in 1910: Cosmopolitanism.

ON Jan. 15th, 1910, the Faculties and mixed Faculties had in all 8029 medical students. Of these 7227 were men, divided into 6600 Frenchmen and 627 foreigners; 802 were females, divided into 312 Frenchwomen and 490 foreign. The students in the medical schools numbered 1692. Of these 1420 were male, 1413 being French and 7 foreign. Of women students 253 were French and 19 foreign. After Paris, which had 2857 matriculated students, the various Faculties came as follows: Lyons, 746 students; Bordeaux, 740; Montpellier, 504; and then Nancy, Toulouse, Lille, and Algiers. As for the schools, Marseilles is at the head with 285 pupils, and next in order come Rennes and Nantes. Besançon closes the list with 31 pupils. Of foreign students enrolled in French Faculties the most numerous are Russian, of whom there are 515 at Paris, 137 at Montpellier, and 29 at Nancy. At Paris, too, there are 62 Turks, 43 Roumanians, and 20 Greeks. Bulgarians are numerous, there being 34 at Nancy and 13 at Montpellier. Nearly every nationality has at least one representative in almost every Faculty, and even in the schools, both preparatory and otherwise. The students of pharmacy number 1448, of whom 53 are women. In these figures are included foreigners of either sex in the higher schools and the mixed Faculties. The schools have 310 pharmaceutical pupils enrolled, of whom 3 are women and 3 male foreign students.

Medical Practice.

The following are the terms of the Act as to Medical Practice in France which has just been gazetted in amendment of that of 1892. Doctors of Medicine, surgeon dentists, and midwives are bound, directly they set up in practice, and before they have performed any act of their profession, to register (without fee) their qualifications at the prefecture or subprefecture and at the depôt of the civil tribunal of their arrondissement. Their qualifications must also be *viséd* at the Mairie of the place where they are domiciled. Those who have not yet received their diploma or certificate must register and cause to be *viséd* a provisional document with which the Faculty or their professional school, supposing the latter to be duly authorised, will provide them.

Excursions for Medical Study to the Thermal Stations of France.

These excursions, which were organised some eleven years ago, were started with the idea of giving both French and foreign medical men facilities for making acquaintance with the French thermal and climatic resorts. An excursion taking in all the stations in one particular district is organised every year during the first fortnight in September. Medical men and medical students, both French and foreign, and the wives of medical men travelling with their husbands alone are eligible for these excursions. The excursion is so laid out that every station may be thoroughly studied in the shortest space of time. This year the excursion will be to Dauphigny and Savoy, and it will be under the scientific direction of Professor Landouzy. All requests for information must be sent to Dr. Carron de la Carrière, 2, Rue Lincoln, Paris.

Aleppo Boil (Bouton d'Orient).

At a meeting of the Academy of Sciences held on April 4th M. Roux, the Director of the Pasteur Institute, gave an account of a discovery made by M. Charles Nicolle, Director of the Pasteur Institute at Tunis, and M. Manceau, one of his collaborators. These two workers have been able to reproduce Aleppo button experimentally and so to give facilities for ascertaining the etiology of the condition.

Typhoid Fever and the City of Paris.

At a meeting of the Society of Medicine of Paris, held on April 8th, Dr. Paul Vincey read a notable paper on the above subject. The frequency of typhoid fever in Paris has greatly diminished during the last half century and the death-rate is now 10 per 100,000 inhabitants. Every *arrondissement* shows a reduction, but those in the centre are more affected than those in the northern district. The 20th *arrondissement*, which is one of the poorest, shows a very low typhoid fever incidence, one cause of this being the rarity of wells in the quarter. In the suburban communes the north-west side of the Seine used to show a higher incidence of the disease than anywhere else. This is mainly due to the fact that the eight communes included in this district drew bad water from the Seine up to the end of 1905. Since the beginning of 1906, however, the water of the Seine has been filtered at the new works of Mont Valerien and the cases of typhoid fever have fallen by one-half. The reduction is less in the low-lying communes owing to the habit of drinking water from wells which are always contaminated.

A Refusal by the Conseil d'État.

Eighteen months ago the Faculty of Medicine received a legacy of 20,000 francs for the purpose of paying the expenses of the publication of certain treatises on homo sexuality. The treatises were to show that this perversion is a real disease which cruelly afflicts the unfortunate persons who suffer from it. The Faculty accepted the legacy and its conditions, but the Conseil d'État has just decided that the legacy cannot be accepted.

April 26th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Myopia and Heredity.

BEFORE the Society for Social Medicine Dr. Czellitzer read a paper on the Hereditary Transmission of Diseases of the Eyes, based on an investigation of the following morbid conditions: (1) myopia; (2) hypermetropia; (3) strabismus; (4) nystagmus; and (5) coloboma. His material included 488 families of the working class and 62 families belonging to the middle classes. The paper only dealt with the conditions in myopia which were prevalent in 230 families of the working class and in 48 families of the middle classes, the number of cases of the other diseases discovered having been too small to allow a distinct opinion. He found that taking the myopic children, in 30·4 per cent. both parents, in 13 per cent. the father, and in 17 per cent. the mother had been myopic, these numbers exceeding fivefold the average number of myopics in the urban population and tenfold that of the rural population. Concerning indirect heredity, it was found that the number of myopics amongst the grandparents exceeded threefold the average for the general population. Crossed heredity—namely, the transmission of myopia from mother to son and from father to daughter—is somewhat more frequent than one-sex heredity. The first-born children are more liable to become myopic than the younger. The age of the father had no influence. Myopia was found to occur with greater frequency amongst girls than boys. Consanguinity of parents without myopia

does not give rise to myopic offspring but may produce other affections of the eyes. Professor Czellitzer suggested a general collective investigation of the matter on a large scale on behalf of the public health authorities.

On Artificial Goitre.

Professor Wilms of Basle, writing to the *Deutsche Medicinische Wochenschrift* upon goitre in animals, said that it was generally admitted that the use of the water of certain wells and springs was the origin of the evil. The prevalence of goitre in certain districts was stopped at once when the water was supplied from other places. The cause of the disease could, however, not be found by microscopical or bacteriological research. From the prevalence of the disease in quite distinct districts a Swiss *savant*, Dr. Bircher, has concluded that the excitant of the disease depends on certain geological conditions of the soil, and is a product of decomposition of organic substances. Professor Wilms is of opinion that these products, being either toxins or ferments, are present in the water. He administered to rats the water of a certain "strumogenic spring" which was brought to Basle, the result being that they showed a marked hyperplasy of the thyroid gland after a few months. When the water had passed through a Berkefeld filter the result was the same. The materies morbi is not a miasma but an organic soluble substance passing through the filter, and Professor Wilms concludes that the usual filters cannot make the water innocuous as far as goitre is concerned. Heating the water had a salutary effect. Four animals received water subjected to temperatures of 50°, 60°, 70°, and 80° C. respectively. The first animal developed a large goitre, the second and third smaller tumours, and the fourth preserved a normal gland; the toxic substance is thus destroyed only at temperatures exceeding 70°. The cause of the swelling of the thyroid gland is, according to the author, that the latter has an increased activity in destroying these substances. On microscopical examination the artificial tumours resembled very closely human goitres in structure. It was, moreover, remarkable that when the water was evaporated in a vacuum its strumogenic action decreased. The author supposes that the lime salts of water agglutinate the toxic substance and thus make the water atoxic. This theory is in accordance with the fact that the Jura Mountains, which are a chalk formation, are free from endemic goitre.

Sterilisation of Linen by Ironing.

It has lately been suggested by Professor Holscher that linen may be sterilised by simple ironing. The Institution for Infectious Diseases has examined whether this statement can be accepted. It was found that the temperature of flat irons was between 150° and 250° C. Pieces of linen impregnated with infected water, cultures of tubercle bacilli, enteric fever bacilli, diphtheria bacilli, cholera vibrios, and different pyogenic cocci were then ironed and their eventual sterility tested. It was stated that spores, e.g., of anthrax in linen, were not even destroyed by ironing at a temperature of 250°. The vegetative forms of micro-organisms were destroyed after ironing at 250°, but at a temperature of 150°, which practically is seldom exceeded, the success was uncertain. Tubercle bacilli, which were destroyed at 250°, proved at 150° to be living but reduced in virulence. The bactericidal action of dry ironing was less effective than that of damp ironing. The results were, of course, better when the linen was ironed on both sides. The report concludes that plain ironing, in which the temperature seldom exceeds 150°, is insufficient to ensure disinfection of linen, 250° being the minimum, and that, therefore, the old recognised methods were preferable in cases where an efficient disinfection is required.

Congress on Criminal Anthropology.

An international congress on criminal anthropology will be held at Cologne in 1911. A provisional committee consists of Professor Aschaffenburg of Cologne, Professor Sommer of Giessen, and Professor Kurella of Bonn, a larger international committee being in formation. The following subjects are to be discussed before the congress: (1) The present state of criminal anthropology; (2) morphological abnormalities, especially of the skull with reference to expert evidence in courts of law; (3) morphology and psychology of the primitive races of the human species; (4) the influence of heredity and of environment on the criminal; (5) the care of criminals with a deficient sense of responsibility; (6) on prisons; (7) the care of the dangerous insane; and (8) the care of young criminals.

Nutrient Suppositories.

Professor Boas has published in the *Berliner Klinische Wochenschrift* an account of his method of rectal feeding by nutrient suppositories. He said that rectal feeding by enema is attended with great drawbacks, the principal one being that only a small quantity of nutrient material is absorbed. The procedure is, moreover, not only troublesome but has also sometimes been followed by decomposition of the food in the intestines causing colic and tenesmus. In a certain number of cases the total stoppage of feeding by the mouth has been found by several observers to produce parotitis. Professor Boas himself once saw purulent colitis develop after a nutrient enema. In the hope of avoiding these mishaps he some years ago recommended the administration of nutrient enemata in drops, a method which prevents the occurrence of painful spasm and allows larger quantities to be retained in the intestine than would otherwise be possible. Recently he has made trials of nutrient suppositories as substitutes for nutrient enemata. The suppositories consist of albumin, especially of the "crystallised" white of hen's eggs, which in combination with common salt is satisfactorily absorbed; the other ingredients comprise dextrin (the least irritating of the carbohydrates) and emulsified fat, for which cacao butter is chosen. Each suppository has a thermodynamic value of 46·2 calories, and as five of them may be given in a day food having a heat-producing power of about 230 calories may be administered in that time. In addition to the suppositories an enema of about 500 cubic centimetres of a physiological salt solution is given twice a day in order to replace the fluid lost by the various processes of excretion. The suppositories are usually absorbed within three or four hours, and expulsion of them unaltered is comparatively rare.

Action against a Medical Journal.

A remarkable decision was recently given by a Berlin law-court in an action brought against the editor of a medical journal which had criticised unfavourably certain compounds prepared at a chemical factory in Hamburg. The manufacturers accordingly wrote to the editor replying to this criticism and demanding insertion of their reply in the journal in accordance with Article 11 of the Press Act. This being refused by the editor on the ground that the reply contained erroneous statements, an action was brought against him, with the result that he was found guilty and was sentenced to a nominal fine of 1 mark. The court said that, according to the law, when a person felt himself prejudiced by an article published in a journal the editor was compelled to insert any communication which such person might send in reply, and that this must be done even when the editor is persuaded that the reply contains untruths!

April 23rd.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Rabies in Western Ontario.

RABIES has certainly become unduly prevalent in Western Ontario. The Canadian Minister of Agriculture and the Veterinary Director-General, acting in coöperation with the health department, have decided to take energetic steps to eradicate the disease. On Feb. 5th an order was issued by the Dominion Department of Agriculture on the report of the Veterinary Director-General directing that all dogs in the western peninsula of Ontario shall be securely chained, or kept under lock and key, or kept constantly muzzled. The provincial Government of Ontario, acting by the advice of the Provincial Board of Health, has issued a similar Order in Council. There have been no deaths among the 42 persons bitten, almost all of whom went to New York to be treated at the Pasteur Institute there. At a recent meeting of the Toronto Academy of Medicine a resolution was proposed to the effect that in view of the prevalence of rabies in Ontario representations should be made to the Secretary of the Provincial Board of Health urging the establishment of a Pasteur Institute in the Province.

Pasteurisation and Care of Milk.

In almost all the large cities of the United States the question of a fairly pure milk-supply has received close attention. In the majority of these the example of New York with regard to pasteurisation has been followed. The general opinion seems to be that while pasteurising milk is not an ideal method it is the best method at hand. In Canada pasteurisation of milk is making considerable headway, and Mr. Charles J. C. Hastings, chairman of the Milk Commission of the Canadian Medical Association, lecturing on the subject, has stated that in his opinion before next summer from 50 to 75 per cent. of the milk sold in Toronto would be quite safe to use. This result, he thought, would be to a large extent brought about by pasteurisation. A pasteurising plant has been installed in the Toronto Children's Hospital and is stated to have had an excellent effect on the health of the inmates.

The Cold Storage of Meat.

In both Canada and the United States the price of food of every description has greatly risen within the past few years and is still rising. This is said to be largely due to the abuse of the cold storage system, the charge being brought against many of the large meat packing firms of the United States that food is held in cold storage frequently for the sole purpose of keeping up the price by controlling the market. The Bill, which has been introduced into the legislature of Massachusetts to regulate the cold storage warehouses in that State, provides that on being placed in, or taken out of, cold storage all food products shall be stamped or otherwise marked with the date upon which such action is taken and that not longer than three months shall intervene at any time between these dates. There is, however, another aspect of the cold storage question which has not been sufficiently considered—namely, the fact that meat which has been retained in cold storage for a considerable period may undergo deterioration and become unwholesome. In Canada it is felt that food products should not be retained in cold storage for several months, as is stated to happen frequently here as well as in the United States. An investigation of the changes which take place in meat kept in cold storage for varying periods would be instructive, and a movement is on foot to this end.

(FROM OUR OWN CORRESPONDENTS.)

Suits for Malpractice in Leaving a Sponge or Pad in the Wound.

THE number of suits for malpractice due to leaving behind a sponge or pad which has been used during an operation seem to be on the increase. The various kinds of defence in these cases form an interesting chapter in medical jurisprudence. In a recent case in Switzerland two eminent surgeons testified that the resemblance of a sponge filled with blood to the tissues of the part was so exact that the most skilful and careful surgeon might overlook the sponge and close the wound with it retained. On the strength of this testimony the verdict was in favour of the surgeon. In a case in a Western State the defence was that the operation ceased when the surgeon ceased to use the knife, and therefore the complaint that he was guilty of gross negligence during the operation was not sustained, as it was admitted on the part of the prosecution that the operation was skilfully performed. The court held, however, that the operation began with the first incision and closed with the finished dressing. In another case in a Southern State the defence was that the enormous amount of detail in modern operations made it quite possible that the most careful surgeon might overlook a sponge or pad. The court sustained that view and the verdict was in favour of the surgeon. In still another case the defence was that the sponges were placed in the care of the nurse, and if any one was left in the wound she was guilty of negligence and not the surgeon. The court held that the nurse was an agent acting under and by direction of the surgeon, and therefore he was responsible for acts performed by her during the operation.

Education in Tuberculosis.

From the fifth annual report of the Phipps Institute, presented by Dr. Lawrence F. Flick, the following principles appear to stand out: That of foreign-born residents who develop tuberculosis in this country, a large number have contracted it from insanitary houses here; that work entailing exposure to dust is the greatest occupational factor; that the mortality is greater proportionately among those who use alcohol and tobacco than among those who do not; that frequent change of residence is a factor, as indicating greater liability to exposure to contagion; that personal contagion is contracted most frequently from those of the same generation (29·37 per cent.), next from the preceding generation (25·81 per cent.), then from fellow employees (11·06 per cent.), the consort's family (8·87 per cent.), contaminated houses (4·64 per cent.), and, finally, from the succeeding generation (3·35 per cent.). Dr. Flick's ultimate conclusion is that "a more intimate knowledge of the subject which has come to us from experience shows us that education by itself cannot accomplish much in the prevention of tuberculosis. For effective prevention isolation of the advanced cases is necessary." In this, perhaps, he overreaches his data. It all depends on what is meant by "education." The effective result of education is the creation of an efficient public spirit, and that is just what is needed to secure the enforcement of the practice of isolation in a popularly governed country. Coercive legislation that is opposed to the general sentiment of the governed will be evaded as much as possible, and either be soon repealed or become a dead-letter. History demonstrates that point over and over again. And such opposition to beneficent measures is in the main the result of popular ignorance. Enlighten the public at large and in due course popular sentiment will support such restrictive and coercive measures against the individual as may show themselves necessary for the public good.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE plague returns for the week ending March 19th show 27,642 deaths, but these include some returns for a fortnight. The Bombay Presidency reports 1035, Bengal 3261, the United Provinces 9211, the Punjab 10,787, Burma 332, the Central Provinces 1068, and Rajputana 1775. There is a great increase in mortality in the Punjab. It is curious to note that the incidence of plague in Bengal varies in a remarkable way from year to year. Thus for 1905 the mortality was 126,000; in the next year it dropped to less than half this number; but in 1907 it again rose to 83,600. In 1908–09 the disease died down except in a few centres, and less than 16,000 deaths were reported. The epidemic was a very local one, as two-thirds of the mortality was in the Patna division, the Monghyr district alone returning nearly one-fifth of the deaths. Bengal has never suffered to the same extent as the Bombay Presidency, the United Provinces, and the Punjab. Calcutta has been spared the terrible mortality which has swept cities such as Bombay and Poona, but plague retains its hold upon parts of Behar and the western districts. It is officially stated that inoculation is still viewed with great distrust by the people, and not more than five or six thousand persons submit themselves to this prophylactic treatment each year. Villagers prefer to evacuate their houses, and in this way some good is effected. It is to be regretted that plague has again appeared in epidemic form in Bengal, a weekly mortality of over 2000 being now reported.

A Pasteur Institute for Assam.

The question of establishing a Pasteur Institute in Assam was raised by Mr. J. R. Macnamara so far back as 1906, when there had been a succession of cases of dog-bites among the employees of the Assam Company. But at that time no station could be found in the province with a sufficiently low temperature for the manufacture of the antirabic serum. Scientific discoveries have since then made it possible to prepare the serum in comparatively high temperatures, and last year the subject was reopened. The India Tea Association was

communicated with, and eventually a small committee, consisting of Mr. Macnamara, Dr. G. C. Winchester, and Dr. W. A. Murray, was appointed to investigate the question. Their report has just been published, and it shows how necessary it is to establish a Pasteur Institute in Assam. During the last four or five years 260 cases of bites by rabic animals have been reported in the province, and of these 16 were sent to Kasauli. There were 60 deaths among the persons bitten. These figures relate only to Assam, and it is probable that they would be doubled or trebled if there had been any record of cases in the more densely populated tracts of Eastern Bengal. The cost of sending patients to Kasauli is heavy, and the long journey, extending in some instances to seven days, lessens the chance of successful treatment. The advantages, therefore, of a local institute are obvious, and it could also be a centre of research for tropical diseases such as kala-azar and blackwater fever. The staff would have ample time for this kind of research work, and as trained bacteriologists would be employed the general results gained would be of the highest value. The committee considers that there would be possibilities for the carrying out of research work unrivalled in any part of the world. The expense involved is not excessive. A capital expenditure of Rs.35,000, in the first instance, would have to be met, and there would be an annual outlay of Rs.9600, if the services of a director and his assistant were given by Government. The small station of Haflong, which is on the railway, seems indicated as a suitable place for the institute. Considering the enormous amount invested in the tea-gardens of Assam there should be little difficulty in raising the sum required. Burma has recently provided Rs.160,000 for a Pasteur Institute, and Eastern Bengal and Assam should be equal to finding more than this, as the big firms in Calcutta and London interested in the tea industry might be asked to subscribe. An endowment fund would have to be provided, and the Government would doubtless give a helping hand.

Sikh Officers in the Indian Medical Service.

It is officially notified that Sikhs serving in the Indian Medical Service are permitted to retain their hair uncut (in accordance with their caste custom) and to wear puggris instead of helmets when in uniform. This order is also applicable to Sikhs undergoing probationary courses at the Royal Army Medical College, London, and Royal Army Medical Corps Depôt at Aldershot.

Civil Surgeoncies in India.

At a recent meeting of the Imperial Legislative Council held at Calcutta, His Excellency the Viceroy presiding, the Hon. Mr. Hague asked for information concerning the number of civil surgeoncies held by the assistant surgeon branch of the subordinate medical department. Replying to Mr. Hague's questions, Sir Harvey Adamson said that the number of civil surgeoncies to be transferred to civil assistant surgeons has been increased since 1899 from 28 to 33. Four of the five new appointments have been added to the list during the last year. Civil assistant surgeons hold 22 of these appointments substantively, 3 in Madras, 3 in Bombay, 1 in Bengal, 4 in the United Provinces, 3 in the Punjab, 4 in Burma, 3 in Eastern Bengal and Assam, and 1 in the Central Provinces. Eleven more medical officers of this class were officiating as civil surgeons on Jan. 1st last. Of the 7 appointments in Bengal, which it was decided in 1899 to transfer to civil assistant surgeons when opportunities offered, 4 are now allotted to Bengal proper and 3 to Eastern Bengal and Assam. It was recognised in 1899 that the arrangement could not be given effect to pending the retirement of the uncovenanted medical officers, European and Indian, then employed in the several provinces. The local governments concerned are aware that the appointments still to be transferred are to be given to civil assistant surgeons when opportunities offer, and the Government of India do not think that it is necessary for them to issue any further orders on the subject. The Government of India have given full and sympathetic consideration to the memorials of civil assistant surgeons in Bengal and to the proposals made to them by the Government of Bengal. They are now about to address the Secretary of State on the subject, and are consequently unable at present to give the information asked for by the honourable member.

Cinchona Bark.

In the Bengal Budget for 1910–11 provision is made for the purchase of no less than two lakhs worth of cinchona bark to supplement the out-turn of the Government plantations. It would be of interest to know whether the purchase is to be made in Holland as heretofore or whether there will be direct buying in Java. The latter course would seem to be the more economical one, as otherwise the bark bought will have travelled all the way from Java to Europe and half-way back again before it reaches the Bengal factory. It is to be hoped that an effort will be made to keep down the prices of quinine sold by State agency, as in the last few years these have compared very unfavourably with the rates quoted by wholesale chemists in India.

April 2nd.

NOTES FROM CHINA.

(FROM OUR OWN CORRESPONDENT.)

The Water-supply of Peking.

THE establishment of a water-supply in Peking, a city of over 600,000 inhabitants and covering an area of 25 square miles is an event of the first importance in public health and sanitary engineering. Hitherto the capital has been dependent on a supply from domestic shallow wells, of which there are thousands. These wells yield a very hard (over 30 degrees), impure water, which increases the sick-rate and is only kept within limits here by being rarely drunk unboiled, thanks to the tea-drinking habits of the people. Notwithstanding this, intestinal complaints, such as typhoid fever, dysentery, diarrhœa, and worms abound. In the Quartier Diplomatique deep wells, ranging from 170 to 300 feet, have been sunk in the various Legations and yield an unlimited supply of pure bacteria-free water averaging 10 degrees of hardness. But with the progressive spirit so much in evidence it was felt that a supply of good, soft, upland-surface drinking water would be appreciated sufficiently to make its installation a paying concern. A Chinese company, with no foreign participation, was therefore formed with a capital of 3,000,000 taels (about £400,000). A good supply of water was available from the Sha Ho, one of a series of rivers running south-east from the great mountain range lying north-west of Peking separating China from Mongolia. This is a shallow river with sandy bed rarely over 2 feet in depth and liable to flood in summer. In winter, though frozen over, the current is too strong for it to freeze through its whole extent and water can always be drawn from beneath the ice coating. Leaving the mountains it passes through cultivated land with a scattered population. No sewers empty into it, as all excreta are applied directly to the fields by the farmers, and the organic matters are thus oxidised by atmospheric oxygen. The intake pipe is at a spot on the river bed 10 miles north-east of Peking. At this place it is estimated that 35,000,000 gallons a day flow past the opening, and of this quantity the waterworks could take up and deal with 3,500,000 gallons or about 150,000 gallons per hour. This is very largely in excess of the demand as not more than 160,000 gallons are used daily. As there had been some discussion as to the advisability of substituting "laid-on" water for that from the deep wells I recently visited the company's works and was very favourably impressed. From the intake pipe the water is drawn through two centrifugal pumps and sent by them to settling tanks. From these it flows over a number of covered filtration beds, where it percolates through a layer of bricks, 4 feet of fine river sand, and 1 foot of gravel. After this it enters the main engine room and is pumped on to the city station, where there are three covered reservoirs of 400,000 gallons capacity each. At this station there is also a water tower, 160 feet high, up which the water is pumped, whence it flows by gravitation throughout the city, being supplied to consumers by street hydrants. of which there are 420, each in charge of a coolie, So little demand has been made for private supply that there are not more than 20 meters at present in use. The main and distributing pipes are of the best type—a German patent called the Mannesmann process, by which a tube of solid forged steel is immersed in a bath of boiling asphalt, which is ingrained in the metal to such an extent that pipes which have lain in sea-water for 30 years have been found quite unaffected. The machinery is also German made and the works have been built under the superintendence of an experienced Danish engineer, Mr. Gimbel. The cost to

consumers is about 10*d.* per 1000 gallons. One hour's pumping a day is sufficient for all the water required. Having now provided an ample supply the company's main business will be to create the demand, for the present rate of consumption only represents a fraction of a gallon per head. In Peking the use of water for personal ablution is reduced to a minimum, as Chinese hardly ever take baths, and there is, moreover, no system of water-borne sewage, nor are there any big manufactories consuming water to any extent. The company will also have to contend with thousands of private wells and an organised system of water-supply from street wells in the hands of a guild of water-carriers. It is interesting to note that the £1 shares now stand at 30*s.* and a divident of 8 per cent. has already been paid, evidently *pour encourager les autres*, as it has been derived from capital, the water having only been turned on for the first time some weeks ago.

April 6th.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in April the following candidates passed in the subjects indicated:—

Surgery.—H. R. L. Allett (Section II.), Sheffield; M. Graves (Section II.), London Hospital; F. F. L. How (Section I.), Middlesex Hospital; B. J. Nolan, Dublin and St. Bartholomew's Hospital; L. M. Potter (Section II.), Geneva and Royal Free Hospital; and G. W. Simpson (Sections I. and II.), London Hospital.

Medicine.—C. S. Foster (Sections I. and II.), Middlesex Hospital; M. Graves (Section II.), London Hospital; C. Pyper (Section I.), Leyden and University College Hospital; L. M. Potter (Section II.), Geneva and Royal Free Hospital; A. H. Rich (Section II.), University College Hospital; H. Stanger (Section II.), Leeds; and W. H. Watson (Section I.), Guy's Hospital.

Forensic Medicine.—K. Baylis, Royal Free Hospital; A. Cordon, Birmingham; M. Graves, London Hospital; C. Pyper, Leyden and University College Hospital; F. C. V. Thompson, Guy's Hospital; and R. P. Wylde, Manchester.

Midwifery.—A. Cordon, Birmingham; H. P. Jelley, Edinburgh; and F. C. V. Thompson, Guy's Hospital.

The diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery:—K. Baylis, M. Graves, H. P. Jelley, B. J. Nolan, and L. M. Potter.

CONJOINT EXAMINING BOARD OF SCOTLAND.—At the recent examinations of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow, held in Glasgow, the following candidates were successful:—

First Professional Examination.—Cyril Popham, James Fitzpatrick, Jeremiah John O'Connell, John Joseph Mulvey, and Violet Millicent Tracey.

Second Professional Examination.—Michael M'Closkey, Andrew Wilson Cochrane, George Agincourt Hodges, William James Hogg, John Edward Rees, and Elliot Paxton Dewar.

Third Professional Examination.—Tom Entwisle Ferguson, Bepin Chandra Sen, Colin Hunter, David Lindsay Hutton, Kedar Nath, James Alfred Frost, and Thomas Nicholson Wilthew.

Final Examination (admitted L.R.C.P.E., L.R.C.S.E., and L.R.F.P.S.G.).—Harold Hope Scott, James Denis Collins, Robert Anderson, George Wallace, Evan Alan Sivell Shaw, and Hopetoun Edward Bond.

FOREIGN UNIVERSITY INTELLIGENCE.—*Göttingen:* Dr. Otto Friedrich Bernhard von Linstow, *Oberarzt*-General, has been granted the title of Professor. *Innsbruck:* Dr. Adolf Posselt, *privat-docent* of Medicine, has been promoted to an Extraordinary Professorship. Dr. Gustav Bayer has been recognised as *privat-docent* of General and Experimental Pathology.—*Kiel:* Dr. Wilhelm Pfeiffer, First Assistant in the University Medical Clinic, has been appointed *Oberarzt*. Dr. Rudolf Hoeber, *privat-docent* of Physiology, has been granted the title of Professor.—*Königsberg:* Dr. Ludwig Wrede, *Oberarzt* of the University Surgical Clinic and *privat-docent* of Surgery, has been granted the title of Professor.

ROYAL INSTITUTION OF GREAT BRITAIN.—The Friday evening discourse next week (May 6th, at 9 o'clock) will be delivered by Sir Almroth E. Wright, who will take as his subject Auto-inoculation. The following three lectures will be delivered at 3 P.M.:—On Tuesday, May 3rd, Dr. Frederick W. Mott, Fullerian professor of physiology R.I., on the Mechanism of the Human Voice (Lecture II.); on Thursday, May 5th, Mr. Walter McClintock, on Blackfeet Indians in North America (Lecture II.); on Saturday, May 7th, Mr. D. H. Scott, on the World of Plants before the Appearance of Flowers (Lecture II.).

FIFTEENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.—We are asked to state that the next Congress will probably be held in Washington, D.C., towards the end of the month of September, 1912.

EAST-END MOTHERS' LYING-IN HOME.—The annual meeting of the friends of this institution will be held at the Mansion House on May 11th. The Bishop of Stepney will speak in support of the work done by the institution, which deserves wider financial support.

THE City of London Hospital for Diseases of the Chest (Victoria Park) will hold a festival dinner on Thursday, May 12th, at which the Hon. L. Walter Rothschild will preside. The dinner will take place at the Trocadero Restaurant and further information can be obtained from the secretary to the hospital.

A MEDICAL CONGRESS IN JAPAN.—A five-days' congress of medical men has lately been held at Osaka, Japan. It is stated that over 3000 medical men were in attendance, and that over 700 addresses were either read or taken as read at the gathering. The subject of beri-beri was discussed at the congress, which appears to have come to the conclusion that there can be no question about a rice diet being the prime cause of the disease. Professor Shiga and Professor Togo described the results of experiments made by them in feeding barn-door fowls and monkeys on rice alone, and from these experiments it became perfectly clear that the disease is produced by such a diet, though, of course, rice may not be the only determining factor. Dr. Adachi attracted much attention by a discourse on the difference between the structure of Japanese and Occidental blood-vessels.

THE CARE OF THE CHILD.—As director of the National Society for the Prevention of Cruelty to Children Mr. Robert Parr has had special opportunities of studying the child question and the effects of legislation in respect to the treatment of the child. In a little book which he has just issued under the title of "Wilful Waste," he reviews in a plain manner the conditions of child life to-day. In the several chapters dealing with infantile mortality, physical and mental deficients, paupers, child labour, and so forth, he throws out many thoughtful suggestions for the preservation of child life and shows the need for a strong impelling force to induce local authorities to take advantage of existing legislation, and to recognise more fully the value of hygiene among school children. In this connexion he naturally lays stress on the importance of medical inspection, but thinks also that one of the first requirements in bringing about better conditions is the formation of a new Government department to deal solely with children. Everyone will not agree with this view. Separate courts of law have a good reason as have separate food menus for children; but after all children are men and women in miniature, and must not be treated as a third species in every relation of life. The book is published by the National Society for the Prevention of Cruelty to Children, Leicester-square, London, W.C., at the price of 6*d.*, and is one which should certainly stimulate thought upon a subject vital to the interests of the nation.

INTERNATIONAL HYGIENE EXHIBITION, DRESDEN (May—October, 1911).—The first conference of the British Executive Committee of this exhibition, presided over by Professor Pannwitz (the official delegate of the German National Committee), took place at the Hotel Cecil on March 11th last, as reported in THE LANCET of March 26th, p. 871. A second conference of the same committee will be held at the Prince's Hall, Hotel Cecil, London, on May 5th next, at 3.30 P.M. The agenda consist of the following items: (1) Election of chairman; (2) formation of British National Committee; (3) election of President and Vice-President; (4) appointment of Executive Committee. About 250 ladies and gentlemen (hygienists and others) have been invited to attend the meeting and 12 different societies have been asked to send delegates. The British Government has now received the invitation from the German Government to take part in the exhibition, and this invitation, it is believed, is receiving favourable consideration at the hands of various Government departments. It is

hoped that a large and fully representative National Committee will be formed in order that the success of the undertaking may be assured. The business management of the exhibition issued from Dresden on April 9th an invitation, written in English, to exhibit in the scientific section. Applications to exhibit are requested to be made before July 1st next. The general secretary for the Scientific Department is Regierungsrat Dr. Weber, Zwickauerstrasse 35, Dresden. The office of the British Executive Committee is at 47, Victoria-street, Westminster, London, S.W., and the Organiser of the Scientific Department is Mr. H. W. Armit.

PRESENTATION TO A MEDICAL PRACTITIONER.—On April 21st at Bodmin, Cornwall, the captain of the local fire brigade (Major W. A. Bawden), on behalf of the members, presented Mr. Bartholomew Gidley Derry, L.R.C.P. Lond., M.R.C.S. Eng., with a barometer, bearing a suitable inscription, as a mark of appreciation for his services as honorary medical officer, an appointment he has held for about 40 years.

SHEFFIELD ROYAL HOSPITAL.—At the quarterly meeting of governors held last week the board of management reported having received an intimation that, owing to the recent death of Major-General William H. Randolph Simpson, the hospital had become entitled, under the will of Mrs. Agnes Elizabeth Randolph Simpson, to a bequest of £7000 or thereabouts for the purpose of endowing beds in the hospital to be called the Barker beds. Mrs. Simpson was a daughter of the late Mr. Thomas Rawson Barker.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of this society was held on April 13th, Dr. G. F. Blandford, the President, being in the chair. Seventeen members of the court were present. Two members of the society had died since the last court, and their widows applied for assistance on behalf of themselves and their children. In both instances they were without any income whatever, and the court voted grants at the rate of £50 per annum for each widow and £15 per annum for each child. By its by-laws the society can only grant relief to the widows and orphans of its deceased members. Membership is open to any registered medical practitioner who at the time of his election is resident within a 20-mile radius of Charing Cross. Full particulars and application forms for membership may be obtained from the secretary at 11, Chandos-street, Cavendish-square, London, W. The next election will be on July 13th, and application forms must reach the secretary on or before June 22nd. The invested funds of the society now amount to £100,550. The date of the annual general meeting has been fixed for Thursday, May 26th, at 5 P.M.

"THE BULLETIN OF ENTOMOLOGICAL RESEARCH."—We learn that the Entomological Research Committee for Tropical Africa is about to establish a journal to be called *The Bulletin of Entomological Research*, dealing with the entomology of tropical Africa. This journal will contain accounts of the observations made by field-workers which may have any bearing on the subject of economic entomology; descriptions of insect life-histories, with figures of their earlier stages; reports on practical methods for destroying or keeping in check any noxious species; papers by specialists dealing with the systematic classification of such groups as are known to be, or are likely to be, injurious to human beings, live-stock, or agriculture; and so forth. The requirements of medical men, farmers, &c., who have no special knowledge of entomology, will also be kept in view; and fully illustrated papers will be issued from time to time showing, as simply as possible, the characters by which the more important pests may be recognised. In this connexion the value of good illustrations cannot be over-estimated, and it is proposed to make these a special feature of the *Bulletin*. Brief accounts will also be given periodically of any useful work and important discoveries that may have taken place in connexion with economic entomology outside the area with which the research committee is more particularly concerned. It is proposed to issue not less than four parts annually, and additional parts will be published whenever sufficient material is forthcoming. Annual subscribers will be entitled to receive such extra parts without further cost. In order to facilitate the prompt publication of important papers the parts will not be issued at fixed intervals but as occasion requires, though, as far as possible, regularity will be maintained. The subscription for the first year will be 10*s*. The separate parts will also be on sale, the prices varying with the size of the part and the number of illustrations. Subscriptions may be sent to the Scientific Secretary, Entomological Research Committee, British Museum (Natural History), Cromwell-road, London, S.W.

COAL SMOKE ABATEMENT SOCIETY.—The annual meeting of this society will be held at the Royal United Service Institution, Whitehall, S.W., at 3 o'clock P.M., on Wednesday, May 4th. The Very Rev. the Dean of Westminster has consented to address the meeting, and an opportunity will be afforded members freely to express their views; those desirous of doing so are invited to send their names to the secretary.

BRUSSELS MEDICAL GRADUATES' ASSOCIATION.—An extra dinner of this association will be held at the Trocadero Restaurant to-day (Friday) at 7 for 7.30 P.M. Tickets 5*s*. (not including wine). Members are invited to bring ladies. All graduates of the University of Brussels are welcome. Applications for tickets to be made to the honorary secretary, Dr. Arthur G. Haydon, 23, Henrietta-street, Cavendish-square, London, W.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Milk and Dairies Bill.

THE Prime Minister having found that Mr. COURTHOPE'S Milk and Dairies Bill will be treated in some quarters as controversial has declined to give Parliamentary facilities for its progress. It is therefore unlikely that it will obtain a second reading this session. The Bill is now published. In a memorandum it is stated that its objects are:—(1) the more effective registration of dairies and dairymen; (2) the inspection of dairies and the examination of cows therein; (3) the prohibition of the supply of milk from a dairy where such a supply has caused, or would be likely to cause, infectious diseases, including tuberculosis; (4) the prevention of the sale of tuberculous milk; (5) the regulation of the importation of milk so as to prevent danger to public health arising therefrom; and (6) the issue of regulations for securing the supply of pure and wholesome milk.

It is further stated by the promoters of the Bill that the provisions as to registration supersede the provisions as to the registration of dairies contained in the Contagious Diseases (Animals) Acts and the orders made thereunder. The provisions as to the inspection of dairies and the prohibition of the supply of milk reproduce with amendment Section 4 of the Infectious Diseases (Prevention) Act, 1890, Section 71 of the Public Health (London) Act, 1891, and the milk clauses incorporated in many local Acts. It also appears that the clause as to the prevention of the sale of tuberculous milk is taken from the Public Health (Scotland) Act, 1897. The Board of Agriculture and Fisheries have prepared an order under the Diseases of Animals Act, 1894, dealing with the notification of tuberculosis in cattle and the inspection, examination, detention, isolation, and slaughter of tuberculous cattle, and the giving of compensation in appropriate cases.

The Provision of Meals to School Children.

Some interesting comments appear in the report of the Board of Education on the working of the Education (Provision of Meals) Act, 1906, up to March 31st, 1909. Accordingly, the report reviews the two years when the feeding of necessitous school children was being developed in some respects tentatively. The relation which this matter must have to the medical inspection of school children is insisted on. On the results which have followed the Act the report proceeds to state that "it is clearly impossible to say with any precision how far the provision of meals has produced an improvement in the mental condition of the children and has rendered them better able to take, in the words of the Act, 'full advantage of the education provided for them.' The Board drew special attention to this point, and many local education authorities have dealt with it in their reply. In a large number of cases they have confined themselves to a general statement that improvement was shown, and some authorities have dwelt upon the fact that the meals increased the regularity of attendance and thus promoted the education of the children. In some cases it is suggested that the provision of meals, by improving the physical condition of the children, rendered them less likely to remain at home for trifling ailments, but it is obvious that the prospect of a dinner may have made the children more ready to come to school." It must be borne in mind that the report does not deal with the experience of the Act obtained during the past year.

The Medical Member of the Prison Commission.

The Government, on Friday, April 22nd, explained its attitude as to the filling up of the vacancy caused by the retirement of Dr. H. B. DONKIN on the Prison Commission by the appointment of a non-medical gentleman. Sir HENRY CRAIK, who, as the Member for the Universities of Glasgow and Aberdeen, represents a large number of medical graduates, voiced the dissatisfaction that a member of the medical profession had not been appointed. He had previously given notice of a question to the Home Secretary on the same subject to be put in the House of Commons on Monday. However, when the occasion for putting the question came Sir HENRY CRAIK, although present in the House, declined to put it. Mr. CHURCHILL, who desired to supplement the information given on Friday, was anxious to answer it, but the Speaker held he could not do so unless it was actually asked.

Mr. CHURCHILL has, however, made a communication of the reply which he intended to make to Sir HENRY CRAIK. It will be desirable to give both the text of the question on the paper and Mr. CHURCHILL'S intended answer. Sir HENRY CRAIK'S question was as follows: "To ask the Secretary of State for the Home Department whether, when the place on the Prison Commission recently rendered vacant by the retirement of Dr. DONKIN was filled, regard was had to the official minute which was placed on record at the Home Office on the undertaking of the First Lord of the Treasury and of the Home Secretary, when the Prisons Act of 1898 was under discussion, and at the urgent request of Members of the present Government, to the effect that one of the Prison Commissioners should, if possible, be a medical man; and why, in view of the minute so placed on record by their own demand, the vacancy was filled by the gentleman who acted as private secretary to the late Home Secretary."

The reply which Mr. CHURCHILL intended to give was in the following terms: "I am informed that the minute in question was fully considered by my right honourable friend. I cannot do better than read its full terms to the House. 'On the passing of the Prisons Act of 1898 through the House of Commons I was urged to accept an amendment to the effect that one of the Prison Commissioners should always be a medical man. I resisted this on the ground that it was not desirable to tie the hands of the Secretary of State. But I gave an undertaking that I would in some way strengthen the medical element in prison administration. There being a vacancy in the summer of 1898 on the Prison Board, I decided to take the opportunity of fulfilling this promise by appointing Dr. DONKIN to it. But I desire to place upon record that it was not my intention to fetter the action of any of my successors, it being conceivable that there might be possibly as effective, or even more effective, a method of carrying out the pledge which I gave to the House of Commons in some other way. I entirely agree with the object in view.—M. W. RIDLEY.' Lord GLADSTONE, whose interest in prison questions is well known and who was chairman of the committee from which the proposal originally emanated, was not likely to overlook this matter. When the time came for Dr. DONKIN'S retirement from his commissionership, he arranged to retain him in a new position in which he is relieved from his former heavy administrative duties and is able to devote himself to medical questions, and in this way the medical influence in prison administration is maintained and strengthened. Dr. DONKIN'S retirement would have been a very serious loss to the medical side of the prisons; but under Lord GLADSTONE'S arrangement he remains in the position of medical adviser and director of convict prisons, and he is present at all meetings of the Prison Board and has an equal voice in all its decisions. Having thus carried further the policy embodied in the minute quoted above, Lord GLADSTONE was able to meet the enormous increase of administrative duties falling on the Prison Commissioners by appointing to the vacancy a man who is a conspicuously able administrator, and one specially qualified by his previous experience and abilities for carrying on the work of prison reform."

Vital Statistics of Scotland.

The annual report of the Registrar-General on the births, deaths, and marriages registered in Scotland during the year 1909, together with the annual report on vaccination, has just been issued as a Parliamentary Blue-book. The outstanding feature of the report is the lowness of the birth-, death-, and marriage-rates, each of these being the lowest recorded in the 55 years covered by the Registrar-General's returns. The national birth-rate for the year 1909 is 26·36, which is 0·60 below that of 1907, which previously was the lowest record. The marriage-rate is 6·17, which is 0·14 less than the previous lowest record, which occurred in the year 1886. The death-rate is 15·29, which is 0·64 less than that of 1905, which previously was the lowest recorded. The population of Scotland in the middle of 1909 is estimated to have been 4,877,648, made up of 2,384,907 males and 2,492,741 females.

The Vaccination (Scotland) Act, 1907, made the conscientious objection on the part of parents a valid excuse for the non-vaccination of children. A comparison of the vaccination returns of the year under review (1908) with those of the three years before the passing of the Act shows that the number of children now remaining unvaccinated is about 20,000 more than it was before the passing of the measure.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 20TH.

The Vaccination Act, 1907.

Mr. POINTER asked the President of the Local Government Board how many declarations were made under the Vaccination Act, 1907, during the year 1909.—Mr. BURNS wrote in reply: The number of declarations received by vaccination officers during 1909 was approximately 190,690.

The Housing and Town Planning Act.

Mr. BOYTON asked the President of the Local Government Board whether he would state the names and qualifications of the officials already appointed by the Board to whom appeals would be referred under Sections 15, 17, 18, and 19 of the Housing, Town Planning, &c., Act, 1909 (relating to contracts by landlords, closing orders and demolition orders, and the redemption of annuities); and whether he would state the officials appointed for carrying out the duties referred to in Section 26 of the Act (which related to inquiries by Local Government Board inspectors as to unhealthy areas).—Mr. BURNS (by written answer) replied: For the purpose of inquiries in relation to appeals under the sections of the Act referred to, as well as for other inquiries under the Housing Acts, the services of the staff of inspectors attached to the Department will be available. I have increased this staff by the appointment of three inspectors, selected by me from a long list of candidates as specially qualified for this purpose—viz., Messrs. Clifton, Collin, and Leonard. Each of these gentlemen had had ample experience in connexion with building construction. For the purpose of inquiries under Section 16 of the Housing Act, 1890, it will be observed that Section 26 of the Act of last session expressly makes the services of the existing staff available. I have, however, made an addition to the staff of medical inspectors by the appointment of Dr. Carnwath, who was formerly assistant medical officer of health to the Manchester Corporation and who has had special experience in the administration of the Housing Acts.

In reply to another question put by Mr. BOYTON, Mr. BURNS stated that six local authorities had been in communication with the Local Government Board with a view to the preparation of town planning schemes. He did not think it desirable at this stage to make the names of these local authorities public.

THURSDAY, APRIL 21ST.

The Milk and Dairies Bill.

Mr. W. PEEL asked the Prime Minister whether his attention had been called to the Milk and Dairies Bill and to the general desire expressed by the representations of producers and consumers alike that general legislation on this subject should be passed this session; and whether, under these circumstances, he would afford facilities for this Bill to be read a second time upon the day when the committee stage of the Consolidated Fund Bill was taken.—Mr. ASQUITH replied: No, sir, I am afraid not. From the information that reaches me I do not think that the Bill in question can be regarded as non-contentious.

Mr. PEEL asked whether the right honourable gentleman was aware that the President of the Local Government Board, speaking on behalf of the Government, had for the last two years given a pledge to bring in a comprehensive measure dealing with the question of the milk-supply of this country.

Mr. ASQUITH: That is so.

Mr. PEEL: Does not that modify the right honourable gentleman's answer?

Mr. ASQUITH: No; the answer which I have given was settled in consultation with the President of the Local Government Board.

University Education in London.

Sir PHILIP MAGNUS asked the Prime Minister whether he could now give an approximate date for the publication of the report of the Royal Commission on University Education in London; whether the evidence already taken was about to be placed at the disposal of the senate of the university; and whether the evidence to be taken in future would also be so placed.—Mr. ASQUITH answered: I understand from the Chairman that steps are being taken with a view to the publication of the evidence already given before the Royal Commission, which will thus be at the disposal of the senate of the university. It is impossible to give an approximate date for the publication of the report of the Commission. The answer to the third part of the question is that this is a matter wholly within the discretion of the Commission.

The Sanitary Condition of Lewis.

Mr. WEIR asked the Lord Advocate whether the Secretary for Scotland was aware that in the report of the sanitary inspector for Ross and Cromarty attention was directed to the report of the local sanitary inspector for the Lewis district, who urged the necessity of new houses on new sites, separated from one another and from the byres, and seeing that a similar view had been expressed by Dr. Dittmar, the medical inspector for the Local Government Board for Scotland, would he state what action the local authority had taken in the matter, and whether the Local Government Board intended to take any steps to secure an improvement in the sanitary conditions in the townships in the island of Lewis.—Mr. URE wrote in reply: I am aware of the report referred to, but am unable to say what action the local authority, who are primarily responsible, have taken in the matter. The sanitary condition of those townships continues to receive the consideration of the Local Government Board.

Grants to Medical Schools.

Sir WILLIAM COLLINS asked the President of the Board of Education whether any medical schools had made application to the Board for grants as technical institutions; whether such grants had been made; and whether he would state the names of such medical schools as had applied, the amounts of the grants, if any, made, and the conditions, if any, attaching to such grants.—Mr. RUNCIMAN replied: Applications have been received by the Board of Education from the following medical schools for grants under the Regulations for Technical Schools, &c., in respect of the academical year 1909–10:—In London: Charing Cross Hospital Medical School, London Hospital Medical School, London (Royal Free Hospital) School of Medicine for Women, St. George's Hospital Medical School, St. Mary's Hospital Medical School, St. Thomas's Hospital Medical School, University College Hospital Medical School, and Westminster Hospital Medical School. In the provinces: Bristol University Medical School, Durham University (Newcastle-on-Tyne) College

of Medicine, Leeds University Medical School, Liverpool University Medical School, Manchester University Medical School, and Sheffield University Medical School. In the case of one of these schools—St. Mary's Hospital Medical School—recognition was accorded in respect of the year 1908–09. In the case of all of them grants will become payable after the close of the present academical year—i.e., July 31st, 1910—provided that the terms of the regulations are found to have been complied with in each case. The amount of grant which will be made in each case will be calculated in accordance with the terms of the Regulations for Technical Schools, &c., having regard to the work done, and therefore cannot be stated until after the close of the academical year.

Cowsheds and Dairies Order (Ireland).

Mr. MEEHAN asked the Chief Secretary to the Lord Lieutenant of Ireland whether, in the event of district councils resisting the enforcement of the Cowsheds and Dairies Order in Ireland, the Local Government Board was empowered to enforce it and surcharge the district council with all cost incurred thereby; and whether such charge, if any, would be an individual or all union charge.—Mr. BIRRELL replied: The Local Government Board is advised that this order may be enforced against a local authority in the same way as other cases of refusal to discharge statutory duties and it would presumably be competent for the court to award costs against the local authority. Such costs would no doubt be payable out of the district fund, but the auditor would have to decide whether the expense had been incurred in circumstances making it a proper charge against the rates.

Mr. MEEHAN further asked the right honourable gentleman whether he was aware that, if the Cowsheds and Dairies Order was enforced by the Local Government Board, it would have a very damaging effect on the coöperative creamery business in Ireland; and whether, having regard to the fact that it penalised those who sold milk to creameries or otherwise, and would have the effect of compelling farmers to revert to the antiquated system of dairying, he would consider the advisability of instituting an inquiry with a view of amending the Act.—Mr. BIRRELL replied: The Local Government Board has no reason to think that this Order will injure creameries or cause a return to the system of home dairying. There is therefore no necessity for the suggested inquiry.

Food Adulteration in the United States.

Mr. STANIER asked the President of the Local Government Board whether he was acquainted with the report of a committee of inquiry which sat in Chicago in 1899 to examine the food then being exported into England from the United States; and whether he had any information as to whether the various forms of adulteration declared by that committee to be generally practised were still continued.—Mr. BURNS replied: I am acquainted with the report referred to. As a result of that report and subsequent legislation a diminution of misdescription and adulteration of foods has no doubt taken place.

Mr. STANIER also asked the right honourable gentleman whether the Government of the United States of America had, so far as he was aware, held any official inquiry in recent years into the forms of adulteration of articles of food or drink in that country.—Mr. BURNS answered: The answer to the honourable Member's question is in the affirmative as far as regards articles of food and drink.

FRIDAY, APRIL 22ND.

The Medical Member of the Prison Commission.

In the course of the debate on the vote on account,

Sir HENRY CRAIK called attention to circumstances which, he said, gave evidence of a grave administrative scandal. Quite recently there had been appointed as a Commissioner, in the place of the Medical Commissioner of Prisons, whose service expired under the age limit, a young gentleman who was ten years ago a clerk in the Home Office and who recently acted as private secretary to Mr. Herbert Gladstone, now Viscount Gladstone. He did not wish to make this a personal question as the gentleman appointed as the Prison Commissioner was a friend of his own. However, a very considerable public interest was involved in the fair treatment of a great profession like the medical profession. If by the common consent of both parties certain offices had been reserved for those who had medical qualifications, the tradition based on general consent should not be lightly departed from, and if it was departed from the profession in question should have an opportunity of protesting. It was not sufficient to say in reply to the point he raised that there were other officers in the service of the Prison Commissioners who could give the necessary advice in regard to medical matters. That had not been the view taken by the party now in office when the general question of a medical member of the Prison Commission was discussed in the year 1898. If a medical member was necessary in 1898, was he not far more necessary now? Had not questions of the greatest delicacy been raised with regard to prison treatment in which medical experts and their advice were specially required? In regard to the treatment of the lady prisoners—the suffragettes, with regard to whom artificial feeding had had to be resorted to—was medical advice not absolutely necessary in deciding what action should be taken? A medical expert ought to be one of the Commissioners who had to decide on such questions. He referred at length to the undertaking given by Sir Matthew White Ridley in the debate on the Prisons Bill of 1898 that he would appoint a medical man as one of the Commissioners. This was done. A few months ago a question was put to the late Home Secretary (now Viscount Gladstone) with regard to the filling up of the prospective vacancy, and he assured the House that care would be taken to keep up the medical element in the Commission. He (Sir H. Craik) would certainly not accept it as satisfactory to be told that Dr. Donkin or any retired official was going to give a certain amount of supervision and advice. That was a mere subterfuge. The only expert advice which was of any real value was that which was given by a man attending daily at his work at the Prison Commission. By omitting to appoint a medical member injury had been inflicted upon the efficiency of the Prison Commission.

Mr. J. A. PEASE (Chancellor of the Duchy) replied on behalf of the Government. He said that no one believed more than Mr. Herbert Gladstone in the necessity for expert medical advice being secured by the Prison Commissioners. He went on to say that three or four months ago, owing to Dr. Donkin having reached the age of 65, he naturally retired, but so much appreciated had his services been by the Home Office that it was thought desirable to appoint him as a special adviser under a special salary. Dr. Donkin, useful as he was as one of the Commissioners, had to devote a great portion of his time to administrative work, and on his retirement from the Commission at the age of 65 a new arrangement was made by Mr. Gladstone that Dr. Donkin, who was a pensioned official, should receive a salary of £200 a year and devote the whole of his time to the work of adviser to the Prison Commissioners. The effect of that had been that the great medical knowledge of Dr. Donkin had been placed entirely at the service of the Commissioners, and the Commissioners themselves had been strengthened by the appointment of Mr. Waller. It had been suggested that there had been a sort of job in the appointment of the private secretary of Mr. Gladstone to the post. Mr. Waller was a man of conspicuous ability. He had not only proved by his experience in the Services and in the criminal department that he was especially qualified for the post, but as secretary to Mr. Gladstone he showed conspicuous ability in the matter of the reforms which Mr. Gladstone had under his charge. He had proved himself not only to be one of the best qualified men for such a position, but he (Mr. Pease) would say that even if Mr. Waller had not been appointed, in Viscount Gladstone's view, some other individual would have had to be appointed in his place as administrator owing to the excessive amount of work that had now fallen to the Prison Commissioners as administrators. Not only had the question of deterrents been kept in view, but also the question of reformation of those who had been sentenced. There had been a State criminal lunatic asylum established at Parkhurst. Great administrative work had been required in connexion with the introduction of preventive detention. There had also been established State inebriate reformatories. It would have been really impossible to carry out these great administrative changes unless the administrative body had been strengthened by the addition of a capable administrator. In order to carry out this very great work a capable administrator, Mr. Waller, had been appointed.

Mr. BALFOUR pointed out that Dr. Donkin, who was now to give his services as adviser, had no control over the Prison Commissioners. He had not a vote in making decisions, and he could not alter their policy by a hair's breadth. He could only give what would no doubt be valuable advice as the result of his long and honourable career as a Commissioner. That, however, did not carry out the policy laid down in 1898. That policy urged primarily by the party now in office was endorsed by the whole House, and was that there should be on the governing body regulating the prisons a trained medical expert. That policy had been abandoned in order to give well-deserved promotion to a distinguished official. By this abandonment, it seemed to him that not merely was an injury done to the medical profession, but, what was more serious, the declared will of the House of Commons had been set aside without excuse or justification.

Mr. MASTERMAN (Under Secretary of State for the Home Department) said that he was quite willing to acknowledge on behalf of the Home Office that the arrangement was a transitory one. He thought that they would have to come to appoint an additional Prison Commissioner, but for the present someone was needed to grapple with the administrative work thrown upon the Commission by new Acts of Parliament. To meet the difficulty Lord Gladstone appointed a man who was acknowledged to be fully competent to deal with the enormous business of administration and at the same time in addition to retain experience, energy, devotion, and enthusiasm. Anyone who knew Dr. Donkin knew that in the new work which had been given to him he would give a good deal more than the mere monetary value. He had promised so to do, and he was now more free to give time to the medical work than he had been during the last ten years. What he wanted the House to realise was that by this change there had been obtained a man who could give his whole time to the work. There had also been got during a time of transition the same medical officer who would be liberated entirely from administrative work in order to give full time to medical work. That was not a bad arrangement in circumstances of some difficulty.

Dr. HILLIER expressed an emphatic opinion in favour of having an expert medical man actively associated with the administrative work of the Prison Commission.

Sir WILLIAM COLLINS hoped that there would be placed on the Commission a medical member who would take his part on an equal footing and standing with other members.

Sir ROBERT FINLAY thought that an additional Commissioner who should be a medical man ought to be appointed.

The subject then dropped.

MONDAY, APRIL 25TH.

Medical Treatment of London School Children.

Sir WILLIAM COLLINS asked the President of the Board of Education whether an application had been made by the London County Council for the recognition of attendances at hospitals of school children for medical treatment as attendances at school for grant purposes, in the same way as recognition was given in respect of their withdrawal for purposes of medical inspection; and whether he proposed to obviate the loss of grant, which would otherwise be incurred in carrying out the provisions of the Education (Administrative Provisions) Act, 1907, by including in the Code for 1910–11 a provision for such recognition in respect of medical treatment similar to that made under Article 44 (h) in respect of medical inspection.—Mr. RUNCIMAN replied: The answer to the first part of the question is in the affirmative. As regards the second part of the question, I am not prepared to extend the scope of Article 44 (h) of the Code as suggested. I am not satisfied that the case has been made out for such an extension of the scope of the Article, and I am unwilling to add to the obligation of our present system of grants.

Vaccination in Leicester.

Mr. CRAWSHAY WILLIAMS asked the President of the Local Government Board whether his attention had been called to the fact that in the Leicester borough police court on April 20th the vaccination officer of Leicester informed the magistrates that he was ordered by the Local Government Board to take proceedings under Section 31 of the Vaccination Act, 1867, even though such proceedings might have been taken under Section 29 of the Act; would he say on what date such an order was issued; and whether it was a general order to all vaccination officers.—Mr. BURNS replied: No order has been issued in regard to this particular matter. I find that the question of procedure under the two sections has been discussed on more than one occasion, when one of the Board's medical inspectors has been inspecting vaccination in Leicester, and that the inspector did not dissent from the view of the vaccination officer that in the circumstances then obtaining procedure under Section 31 was preferable.

Medical Examination of Special Reserve, Belfast.

Mr. PATRICK WHITE asked the Secretary of State for War how many civilian medical officers were at present engaged, or likely to be engaged, in the Belfast district in connexion with the annual Militia training; would he state the particular localities to which they were attached; how many Army medical officers were there in the same district; and what was the respective cost of army and civilian officers for the same period.—Mr. HALDANE wrote in reply: There are no civilian medical officers at present engaged in connexion with the annual training of the Special Reserve in the Belfast district. However, about 14 will probably be required to assist in the medical examination of the men on their assembling for training. This duty will occupy from one to two days in each case and is paid for at the rate of a guinea a day. There are 17 army medical officers at present serving in the Belfast district and the employment with the Special Reserve will not entail any extra cost on the public.

Asylum Attendants in Ireland.

Answering Captain CRAIG,

Mr. BIRRELL (Chief Secretary to the Lord Lieutenant for Ireland) said that the Inspectors of Lunatics in Ireland informed him that, so far as they were aware, there was no general feeling amongst attendants in Irish asylums that their hours were too long. It was a fact that consumption was very prevalent amongst the insane, but it must be borne in mind that the patients affected in asylums were under constant medical supervision and that efforts were made to keep the insane as much as possible in the open air. The inspectors did not consider that the statement that many attendants died from consumption contracted from patients was correct.

Metropolitan Street Accidents.

Sir WILLIAM COLLINS asked the Secretary of State for the Home Department to state the number of persons injured in the streets within the metropolitan area as the result of accidents known to the police during the year 1909, and how many of these terminated fatally.—Mr. CHURCHILL wrote in reply: The total number of persons injured in the streets in the Metropolitan Police District last year is not at present available, and would take some time to compile. But 16,842 accidents caused by vehicles and resulting in personal injury are known to the police to have occurred during 1909. Of these 306 cases ended fatally.

TUESDAY, APRIL 26TH.

Metropolitan Ambulances.

Sir WILLIAM COLLINS asked the Secretary of State for the Home Department whether he was prepared to sanction the coöperation of the police in the manner recommended by the Departmental Committee of 1906-9 in the event of the London County Council establishing a rapid ambulance service, summonable by telephone, in accordance with their powers under the Metropolitan Ambulances Act of 1909.—Mr. CHURCHILL wrote in reply: I have not any information as to the intentions of the London County Council in this matter, but I need not say I shall be happy to give my best consideration to any proposal that may be put before me with every desire to sanction, so far as may be practicable, the coöperation of the police.

Mr. HAY MORGAN also asked whether the right honourable gentleman was aware that hand-stretchers were still used by the Metropolitan Police for conveying persons who had suffered serious injuries to the hospital; and whether he would see that the supply of motor ambulances was increased so as to avoid the necessity of resorting to the use of hand-stretchers in cases where time might be a matter of life or death to the person injured.—Mr. CHURCHILL (in a written answer) replied: Hand-stretchers have not been used for this purpose by the Metropolitan Police for many years, but wheeled litters of an approved pattern are so used. The London County Council last year obtained Parliamentary powers for the provision of motor ambulances, and I understand this question is now engaging the attention of the Council.

BOOKS, ETC., RECEIVED.

ADLARD AND SON, London.
Spa Treatment: Selection of Patients and the Choice of a Suitable Spa. By Neville Wood, M.D., M.R.C.P. Price 1*s.* 6*d.* net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

ANDERSON, H. GRAEME, M.B., Ch.B. Glasg., F.R.C.S. Eng., has been appointed Registrar and Pathologist to the Metropolitan Hospital.

BALLANCE, HERBERT STANLEY, M.D., B.S. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Surgeon to the Weston-super-Mare (Somerset) Hospital and Dispensary.

BAYLISS, A. D. E., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician at University College Hospital.

BREBNER, C. S., M.D., B.S. Edin., D.P.H. Cantab., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Widnes District of the county of Lancaster.

DALLY, J. F. HALLS, M.D. Cantab., M.R.C.P. Lond., has been appointed Assistant Physician to the National Hospital for Diseases of the Heart, Soho-square.

DAWNAY, A. H. PAYAN, F.R.C.S. Eng., has been appointed Assistant Surgeon to the Western Ophthalmic Hospital, Marylebone-road.

FLETCHER, JAMES, M.D., C.M., D.P.H. Aberd., has been appointed Medical Superintendent of Monsall Fever Hospital, Manchester.

GALLAGHER, FLORENCE A., M.B., B.S. Glasg., has been appointed Assistant Resident Medical Officer to the Merthyr Tydvil (Glamorganshire) Workhouse Infirmary.

HOWARTH, W. G., M.B., B.C. Cantab., F.R.C.S. Eng., has been appointed Surgeon to the Throat, Nose, and Ear Department at the Queen's Hospital for Children.

MCILROY, ALEXANDER JOSEPH, M.B., M.S. Edin., has been appointed Public Vaccinator for the District of Clutha, New Zealand.

MILLS, A. E., M.B., Ch.M. Syd., has been appointed Lecturer in the Principles and Practice of Medicine in the University of Sydney, New South Wales.

PORTER, HERDMAN, M.B., Ch.B. Edin., has been appointed Clinical Assistant to the Ear and Throat Department, Prince of Wales Hospital, Tottenham.

SCOTT, GEORGE MELMOTH, M.D. Cantab., has been appointed Public Vaccinator for the District of Marton, New Zealand.

THORBURN, WILLIAM, M.D., B.S. Lond., F.R.C.S. Eng., has been appointed Professor of Clinical Surgery in the University of Manchester.

TODD, R. H., M.D. Dub., F.R.C.S. Irel., has been appointed Lecturer in Medical Jurisprudence, University of Sydney, New South Wales.

WILSON, ALEXANDER, M.B., Ch.B. Aberd., has been appointed Assistant to the Professor of Anatomy in Sheffield University.

YELF, R. E. B., M.B., M.S. Edin., has been appointed Medical Officer of Health to the Stow-on-the-Wold Union.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BATH, ROYAL MINERAL WATER HOSPITAL. Resident Medical Officer. Salary £100 per annum, with lodging, board, and washing.

BIRMINGHAM AND MIDLAND EAR AND THROAT HOSPITAL, Edmund-street.—House Surgeon for six months. Salary at rate of £70 per annum, with board, lodging, and washing.

BIRMINGHAM, ROYAL ORTHOPÆDIC AND SPINAL HOSPITAL.—Honorary Surgeon.

BRIDGWATER HOSPITAL.—House Surgeon, unmarried, for six months. Salary at rate of £100 per annum, with board, lodging, and washing.

BRIGHTON COUNTY BOROUGH ASYLUM, Haywards Heath.—First Assistant Medical Officer and Pathologist, unmarried. Salary £250 per annum, with apartments, board, laundry, and attendance.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—Secretary. Salary £250 per annum, with £100 in lieu of apartments and board.

BRISTOL GENERAL HOSPITAL.—Medical and Surgical Registrars.

BRISTOL ROYAL INFIRMARY.—Honorary Medical Registrar.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—House Surgeon, unmarried. Salary £80 per annum, with board, lodging, and washing.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistant.

CHESTER, COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £160 per annum, with board, lodging, and washing.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Honorary Aural Surgeon.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant Resident Medical Officer, unmarried, for six months. Salary at rate of £50 a year, with board, apartments, and laundry.

DOUGLAS, NOBLE'S ISLE OF MAN GENERAL HOSPITAL AND DISPENSARY.—Resident House Surgeon, unmarried. Salary £90 per annum, with board and washing.

GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and washing.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with board, residence, and laundry.

HALIFAX, ROYAL HALIFAX INFIRMARY.—Second House Surgeon, unmarried. Salary £100 per annum, with residence, board, and washing.

HEMEL HEMPSTEAD, WEST HERTS HOSPITAL. — House Surgeon. Salary £100 per annum, with rooms, board, and washing.

HOSPITAL FOR EPILEPSY AND PARALYSIS AND OTHER DISEASES OF THE NERVOUS SYSTEM, Maida Vale, W.—Resident Medical Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

HULL, ROYAL INFIRMARY.—House Physician, unmarried. Salary £100 per annum, with board and apartments. Also Assistant House Surgeon. Salary £80 per annum, with board and lodging. Also Casualty House Surgeon. Salary at rate of £60 per annum, with board and lodging.

ITALIAN HOSPITAL, Queen-square, W.C.—Honorary Assistant Physician. Also Honorary Anæsthetist.

LEICESTER INFIRMARY.—Assistant House Physician and Assistant House Surgeon. Salary at rate of £60 per annum, with board, apartments, and washing.

LONDON COUNTY COUNCIL.—Medical Examiner to Men working in Compressed Air at Woolwich Tunnel. Salary at rate of £10 a month.

LONDON HOSPITAL, Whitechapel, E.—Assistant Surgeon. Also Surgeon.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—House Surgeon for six months. Salary £50 per annum.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT AND CHEST.—Resident Medical Officer. Salary £100 per annum, with board, apartments, and washing.

MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Honorary Physician.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—House Physician. Salary £75 per annum, with board and residence.

NOTTINGHAM GENERAL HOSPITAL.—Locum Tenens. Salary £45, with board, lodging, and washing.

PAISLEY, INFECTIOUS DISEASES HOSPITAL.—Resident Medical Officer and Assistant Bacteriologist. Salary £130 per annum, with board, washing, and attendance.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Also House Physician. Salary £75 per annum, with board, residence, and washing.

PRESTON, LANCASHIRE EDUCATION COMMITTEE.—Two School Medical Inspectors. Salaries £250 per annum.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, 234, Great Portland-street, W.—Resident House Surgeon, unmarried. Salary £100 per annum, with board, residence, and washing. Also Honorary Anæsthetist.

ROYAL NAVAL MEDICAL SERVICE.—Examination for Fifteen Commissions.

SALFORD UNION INFIRMARY, Hope, Pendleton.—Resident Assistant Medical Officer. Salary £120 per annum, with apartments, attendance, and rations.

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.—Clinical Assistants.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.

SHEFFIELD, WEST RIDING ASYLUM, Wadsley.—Fifth Assistant Medical Officer. Salary £140 per annum, with board, &c.

SOUTHWARK UNION INFIRMARY, East Dulwich-grove, S.E.—Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing.

STOKE-ON-TRENT, NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill.—Junior House Surgeon for six months. Salary at rate of £50 per annum, with board, apartments, and washing.

SWANSEA GENERAL AND EYE HOSPITAL.—House Physician. Salary £75 per annum, with board, washing, and attendance.

TYNEMOUTH, VICTORIA JUBILEE INFIRMARY, Spring Gardens, North Shields.—House Surgeon. Salary £100 per annum, with rooms, board, &c.

VENTNOR, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—Two Assistant Resident Medical Officers, unmarried. Salary £100 per annum each, with board and lodging. Also Holiday Locum Tenens for four months. Salary £3 3s. per week.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Surgeon for six months. Salary £30, with board, lodging, and laundry.

WESTERN OPHTHALMIC HOSPITAL, Marylebone-road, N.W.—Honorary Anæsthetist.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon. Salary £80 per annum, with board, rooms, and laundry.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Blackford, in the county of Perth; at Radstock, in the county of Somerset; and at Gainsborough, in the county of Lincoln.

Births, Marriages, and Deaths.

BIRTHS.

BUNTING.—On April 22nd, at Hagley-road, Edgbaston, the wife of W. Hartley Bunting, M.D., F.R.C.S. Edin., of a daughter.

GLASIER.—On April 25th, at Mildenhall, Suffolk, the wife of Howard Glasier, M.A., M.B. Cantab., M.R.C.S., of a daughter.

GOUGH.—On April 22nd, at Glenallon, Torquay, the wife of John Harley Gough, M.D., B.Sc., F.R.C.S. Edin., of a son.

HARRIS.—On April 23rd, at Wimpole-street, W., the wife of Dr. Wilfred Harris, of a son.

HAY.—On April 18th, at Lincoln-road, Peterborough, the wife of William Peach Hay, M.B., C.M., of a son.

MURPHY.—On April 21st, at Waterloo-crescent, Dover, the wife of Charles E. Murphy, F.R.C.S., of a daughter.

WOAKES.—On April 26th, at 46, Wimpole-street, the wife of Claud Woakes, of a daughter.

MARRIAGES.

BURTON-MARSHALL—BORASTON.—On April 21st, at St. Peter's, Eaton-square, S.W., William Burton-Marshall, M.B., B.C. Cantab., M.R.C.S., &c., to Kathleen, younger daughter of Mr. John Boraston.

JEFFERISS—GILL.—On April 21st, at St. Martin's, Herne, by the Rev. Giles Daubeney, M.A., Frederick Burroughs Jefferiss, F.R.C.S., son of W. R. S. Jefferiss, M.D., of Chatham, to Marjorie Emilie, youngest daughter of Edwin Gill, of St. Brelades, Herne Bay, and Rochester.

DEATHS.

CAPPE.—On April 22nd, at Belsize-square, N.W., Herbert Nelson Cappe, M.R.C.S., L.R.C.P. Lond., Senior Medical Officer, Surrey County Asylum, Brookwood, aged 44 years.

EDGINTON.—On April 20th, at St. Thomas's Hospital, Alfred Dudley Edginton, M.R.C.S., L.R.C.P., of 154, High-street, Battersea, aged 50 years.

SPARKES.—On April 23rd, at the Cambridge Hospital, Aldershot, Claude Stephen Sparkes, Lieutenant-Colonel R.A.M.C., on his 51st birthday.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE SOOTHER.

To the Editor of THE LANCET.

SIR,—The "monthly nurse" has the greatest influence for the use or banishment of the "soother." Every woman, I presume, in the middle and lower middle classes engages a "monthly nurse" for her confinement. For the first two or three weeks that nurse's word is law as far as the baby is concerned. She uses a soother that the mother may not be worried by baby's crying. Eighteen to thirty years ago I found some difficulty in preventing the nurse using the soother, but events have proved I could not do it at all now. Having seen the more than usual bad effects on one child, when asked to find a nurse for a mother expecting her first baby, I tried my best to get one who would not use a "soother." One trained nurse wrote: "I could not help laughing at what you say about the dummy, and felt sorry for the poor young mother, when she wants to work and the baby won't be good," &c.: She thought evidently I was quite behind the times. I eventually engaged an untrained woman who said she did not use a soother. (This was an elderly woman seldom without a case.) When she had gone at the end of the month she certainly had not used the soother, though one had been duly bought, but I found she had given bread, sugar, and *something* (I forget what now) tied up in the corner of a *handkerchief*. To continue this plan seemed too awful, and as the baby would not lie down without something to suck a soother had to be bought after all. Many will say patience and perseverance would have conquered the habit, but as on two or three occasions the child deprived of the soother screamed until she was blue, I thought perseverance had been exhausted. It is in the first few weeks that the habit of sucking is made and cannot easily be broken. There is one reason, I consider, why the nurse of to-day insists on using a soother. She is taught such hard-and-fast rules about the times of feeding. The baby is to be fed at first every two hours; even if asleep to be roused. That seems so unnatural. A baby is an animal, not a mechanical toy. What other animal is fed at certain times and no other and not allowed to have its sleep out? I think (but I am not a doctor) a baby, if normal, should not be roused to be fed. It should be fed just as long as it will really feed, not the present hard-and-fast 20 minutes. Now, if it starts crying again and nothing will stop it, it is better to feed it again than to use the soother. I quite agree that it cannot be allowed to cry for an hour and forty minutes. If the baby is breast-fed, who is to know how much it has had? If the soother has been used it has been probably too tired to take but little. If brought up by hand, the nurse can see how much the baby has taken and can act accordingly. It is better even then to give a little more food than to use the soother.

I am, Sir, yours faithfully,

April 23rd, 1910. ANOTHER GRANDMOTHER.

*** Since a "Grandmother" contributed to our columns on this subject we have received quite a large number of letters from other grandmothers, and we have come to the conclusion that grandmothers form a very wise and observant class. We cannot publish the letters which we have received because our space is required for medical correspondence, nor do we endorse everything in the above letter. We agree, however, with the general opinion that soothers are mischievous appliances and that their use is due in many instances to the initiative of the monthly nurse.—ED. L.

TEACHING OF HYGIENE IN TRAINING COLLEGES.

THE Board of Education in its annual report for 1908–09, just issued, states, in the section dealing with the training of teachers, that up to 1907 hygiene had been taken by a certain number of students at particular colleges, but no systematic provision was made for instruction in that subject. In 1907, however, the Board issued a new syllabus in hygiene, which was required to be included in the curriculum of every training college, except in the case of students taking degree courses, who have not sufficient time unfortunately for this most desirable subject. Increased attention has been given to the subject of physical training during recent years. The Board has issued a model syllabus of physical exercises which has been revised from time to time in the light of experience, and has recently been reissued with changes and improvements. Students in training colleges are now required to go through a course which will qualify them to teach physical exercises in the schools, and two women inspectors for this subject have recently been appointed to visit women's and men's colleges respectively, the whole subject being supervised by the medical department of the Board. The greater attention which is now being given to hygiene and physical training, and which will, it is hoped, be given in the future to manual training, should do much to increase the practical efficiency of the teaching given in the elementary schools. The Board regrets that it is not at present possible to require these three subjects to be included in the course of students taking degree courses, owing to the insufficient time at its disposal, but it hopes that this difficulty may be surmounted in future. In August of 1909 the Board held a course of instruction in hygiene, including physical exercises, for members of the staffs of Training Colleges for Elementary School Teachers. The course lasted three weeks and was intended to explain and illustrate the syllabus of hygiene and the revised syllabus of physical exercises. Lectures on hygiene were delivered by Dr. H. R. Kenwood, Chadwick Professor of Hygiene in University College, London, who also took the students on expeditions to study on the spot modern methods of sanitation and ventilation in public elementary schools. The instruction in physical exercises was undertaken by Lieutenant Grenfell, and Miss Koetter, formerly one of the teachers of physical exercises under the London County Council. Lectures and practical instruction in the exercises were given. Games and dancing steps were also taught. The London County Council kindly placed the premises of the London Holborn Day Training College at the disposal of the Board for the course, which was attended by 15 men and 39 women, the great majority of whom had had practical experience as teachers of one or other of the subjects. Great interest and keenness were displayed, and there is every reason to hope that the course proved of practical value and assistance to those who attended it.

THE PETROL REBATE.

To the Editor of THE LANCET.

SIR,—On Feb. 26th last the *Autocar* told "doctors ..... how to obtain the full rebate," and on its advice I wrote to the local officer of Customs and Excise for form No. 232 B, and sent in my claim, which is still in the hands of the authorities, but I am led to understand that it will be paid when I have furnished the officer with: (1) details of petrol purchased by me; with (2) a verification of this quantity by the garage that supplied me; and (3) a certificate from their manufacturers that said petrol had paid the full duty. A simpler procedure could easily have been devised, but as things are I would advise "R. S. T." to do as I have done and then "wait and see."

I am, Sir, yours faithfully,

Grange-over-Sands, April 25th, 1910. WILLIAM A. FOX.

THE ALLEGED DANGERS OF THE DAILY "TUB."

A RECENT number of the Spanish magazine *Alrededor del Mundo* (*Around the World*) contained an article decidedly unfavourable to the use of the daily "tub," and an English correspondent residing in Spain has sent us the paragraph in question. Without expressing any opinion of its own, either for or against the "tub," our contemporary professes only to put before its readers the denunciations of "el baño ó el 'tub' diario" which have proceeded from two Englishmen. These gentlemen are represented as objecting strongly to the free use of soap in a bath; they consider that daily bathing is injurious to the epidermis, increases individual susceptibility to atmospheric changes, and is peculiarly harmful to children. Possibly the Spanish journalist may have made a skilful combination of selected quotations with an eye to heightening the effect of his paragraph, but whether this be so or not it seems clear that the case against the tub is overstated. We think that a bather after a cold bath who on drying himself feels a sensation of warmth and comfort will be the better for his bath and not the worse; while, on the other hand, any tendency to subsequent shivering or uneasiness is a contra-indication. This is the usual medical view, and we have not heard it challenged; of course, special pathological states are not taken into account. Warm baths are necessary to cleanliness, and their frequency should depend upon the occupation followed.

A MENSTRUAL PUZZLE.

To the Editor of THE LANCET.

SIR,—In submitting the following case for suggestions I must say I have often derived a hint from similar cases, and I might almost suggest having a separate column for such puzzling cases and their treatment. My case is that of a young single woman, otherwise in perfect health, who at each menstrual period has a typical "bilious" attack. The day before the menses appear she is quite prostrated with headache and squeamishness, which almost always ends in frequent retching and vomiting of bile. There is no uterine or pelvic pain and the flow is not particularly strong, lasting about three days. She has had hot hip-baths, hot douches, blue pill, or calomel on the day antecedent to the expected attack, but nothing seems to help. Sedatives, bromides, camphor, all the same. She is otherwise a healthy, strong girl, playing tennis and hockey well. I should be glad of any hints as to treatment.

I am, Sir, yours faithfully,

JOHN A. GRAHAM, M.B. Glasg.

Bethulie, South Africa, April 2nd, 1910.

A DIAGNOSTIC POINT.

WE have received a communication from Mr. G. Sherman Bigg drawing attention to a matter in clinical examination which he deems of importance. He commences by laying stress on the necessity of differentiating between functional and organic disease, especially with a view to "radical treatment." He states that "when the two radial pulses differ in strength from one another, and also differ in strength from the force of the heart's apex beat," the existence of structural change may with confidence be diagnosed. He further says that this evidence is of positive but not necessarily of negative value, for if this sign is present "there is structural change, though

structural change may exist without it." Mr. Bigg's statement is difficult to follow, as the term "structural change" is rather vague; he adds, however, that this phenomenon for the most part has been noticed in digestive disorders, but it has also been evident in connexion with structural change in other organs. Mr. Bigg omits to mention a fallacy that might easily render this observation less definite than his statement would indicate—namely, that it is not an uncommon occurrence for the radial arteries to differ in size this might give rise to the impression that they differ in strength. Mr. Bigg's suggestion, however, can be readily tested and its exact value estimated by other practitioners.

CRIME AND THE MEDICAL MAN.

To the Editor of THE LANCET.

SIR,—I am called by a stranger to go to a certain address. I go, and find a woman with a knife in her back, alone. She recovers. She tells me she knows who stabbed her, but refuses the name. Have I any obligation in the matter as regards informing the police? If so, what?

I am, Sir, yours faithfully,

April 22nd, 1910. INQUIRER.

*** There is no obligation upon our correspondent in the circumstances mentioned to give information.—ED. L.

THE GRATUITOUS MEDICAL CERTIFICATE.

A CORRESPONDENT has raised an old question by pointing out that a certain life insurance company, which is not, we understand, alone in its practice, refuses to accept the direct certificate of death from the medical man, but demands the registrar's certificate, which is a copy of the medical man's certificate. The point has been raised before and we fear that we have no suggestion of remedy to offer in the existing state of the law.

BRUSSELS INTERNATIONAL EXHIBITION.

IN connexion with the Brussels Exhibition, which was opened on April 23rd, the Great Eastern Railway Company has arranged to issue cheap return tickets, 1st class 38*s.* 6*d.*, 2nd class 24*s.*, available for 14 days, *vid* Harwich and Antwerp.

A. B. C.—In answer to the question about eligibility for active service abroad of a Territorial officer myopic in one eye, but wearing a correcting lens, the officer might be eligible; but it depends on the degree of myopia, and on whether it can be corrected. A Territorial officer could get a commission in the Regular Army, even if he can only read D = 24 with each eye at 6 metres (20 feet), provided he can correct it with glasses so as to be able to read D = 6 with one eye and D = 12 with the other at 6 metres; and also be able to read D = 0·8 with each eye without glasses at any distance he likes. Further, if *one* eye is so short-sighted that he can only read D = 36, he would be eligible provided he can read D = 6 with the other eye and can read D = 12 with the myopic eye by the aid of glasses. If he *cannot* read D = 24 at 6 metres with each eye without glasses he is *unfit*; but this is a high degree of myopia, only one-quarter of normal vision. The point in this particular case is, Can he read D = 6 with his good eye, and can he read D = 12, *with a glass*, with his bad eye? If so, he would be eligible for a commission in the Regular Army and *a fortiori* for active service as a Territorial. He would also have to read D = 0·8 without glasses at any distance, but this is no serious test for a myopic man. The whole point of recent modifications in eye tests in the army (1909) has been to make the regulations easy for *simple* myopia, only excluding *diseased* conditions.

L.R.C.P.I.—The gentleman about whom our correspondent inquires is an M.B. The words "Examiner in the Faculty of Medicine" mean that the person in question examines or used to examine in medicine. Faculty is the technical term for a body of teachers of one subject, and is also applied to the subject itself. There are three "superior faculties"—namely, Divinity, Law, and Physic.

Mr. Wm. Boothman must consult his usual medical attendant. It is quite possible that he is right in his feeling of plethora.

Law.—We have no information as to the matter referred to by our correspondent.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

TUESDAY.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION (Hon. Secretaries—J. Gray Duncanson, H. Charles Cameron) at 15, Cavendish-square, W.: at 4.30 P.M.

Annual General Meeting.

Papers:

Dr. C. Bolton: Some Points in the Treatment of Gastric Ulcer.

Dr. Langdon Brown: An Inquiry into the Value of Rectal Feeding.

FRIDAY.

LARYNGOLOGICAL SECTION (Hon. Secretaries—George C. Cathcart, L. Hemington Pegler) at 11, Chandos-street, W: at 5 P.M.

Cases:

Cases will be shown by Dr. Dundas Grant, Mr. Herbert Tilley, Mr. A. R. Tweedie, Dr. Watson Williams, Dr. G. C. Cathcart.

SATURDAY.

OTOLOGICAL SECTION (Hon. Secretaries—Hunter F. Tod, H. J. Marriage) at 11, Chandos-street, W.: at 10 A.M.

Cases and Specimens:

Dr. Wyatt Wingrave: Notes on the Pathology of Cholesteatoma.

Mr. A. L. Whitehead: Notes of a Case of Temporo-sphenoidal Abscess in which Vomiting was entirely Absent.

Dr. P. H. Abercrombie and Dr. Dan McKenzie: Hysterical Deafness with Active Vestibular Reactions.

Dr. H. J. Davis: Deformity of Both Pinnæ resulting from Perichondritis following Double Mastoid Operation.

Mr. Hunter Tod: (1) Exostosis of Right External Meatus in a Boy; (2) A Case in which the Clinical Symptoms Simulated a Cerebellar Abscess—Brain Explored on Two Occasions—No Abscess Discovered—Recovery; (3) Specimen of Cholesteatoma or Keratosis Obturans of the External Auditory Canal.

Mr. George Wilkinson: Two Cases of Cholesteatoma of Unusual Size Extending into the Posterior Fossa and Causing Obliteration of the Sigmoid Sinus.

Dr. P. Watson Williams: Myelogenous Sarcoma of the Right Temporal Bone with Extension through the External Meatus, Resembling an Aural Polypus.

Mr. G. J. Jenkins: Fracture of the Temporal Bone.

COAL SMOKE ABATEMENT SOCIETY, Royal United Service Institution.

WEDNESDAY.—3 P.M., Meeting.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Clinical Cases.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 11, Chandos-street, Cavendish-square, W.

THURSDAY.—8 P.M., Card Cases by Mr. H. Herbert, Dr. A. S Worton, Mr. J. H. Tomlinson, and others. 8.30 P.M., Mr. H Herbert: A New Operation for Glaucoma.—Dr. J. H. Fisher Congenital Word-Blindness.—Dr. A. Bronner: Some Cases o Hypopyon Keratitis Treated with Pyocyanese.—Dr. E. Clarke Optic Atrophy Following the Use of Orsudan and Soamin.

RONTGEN SOCIETY, 20, Hanover-square, W.

THURSDAY.—8.15 P.M., Mr. J. H. Gardiner: Quantitative Measure ments of the Conversion of Kathode Rays into Röntgen Rays b Antikathodes of Different Metals.

HARVEIAN SOCIETY OF LONDON, Paddington Infirmary.

THURSDAY.—8.30 P.M., Clinical Evening.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. G. Little: Clinique (Skin). 5.15 P.M. Lecture:—Dr. F. M. Sandwith: Malta Fever.

TUESDAY.—4 P.M., Dr. T. N. Kelynack: Clinique (Medical). 5.15 P.M. Lecture:—Mr. M. Davidson: Localisation by Means of X Rays

WEDNESDAY.—4 P.M., Mr. D. C. L. Fitzwilliams: Clinique (Surgica 5.15 P.M., Lecture:—Mr. E. Clarke: Optic Atrophy (wi lantern slides).

THURSDAY.—4 P.M., Sir Jonathan Hutchinson: Museum Demonstr tion. 5.15 P.M., Lecture:—Dr. StClair Thomson: The Operati of Laryngo-Fissure and its Indications.

FRIDAY.—4 P.M., Mr. J. G. French: Clinique (Ear, Nose, a Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmi road, W.

MONDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstratio Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Ra Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operatio 2 P.M., Medical and Surgical Clinics. X Rays. Operatio Dr. Davis: Operations on the Throat, Nose, and Ear. 2.30 P. Dr. Abraham: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Childr Dr. Davis: Diseases of the Throat, Nose, and Ear. 2 P. Medical and Surgical Clinics. X Rays. Operations. Mr. Harman: Diseases of the Eye. 2.30 P.M., Diseases of Wom

THURSDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. Dunn: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Diseases of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 3.30 P.M., Special Lecture:—Mr. Cargill: Sympathetic Ophthalmitis.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 2.30 P.M., Special Lecture:—Dr. G. Rankin: Duodenal Ulcer.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture:—Dr. R. Bradford: Angina.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. D. Grant: Lesions Simulating Laryngeal Tuberculosis.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Dr. Atkinson: Nose.
FRIDAY.—Dr. D. McKenzie: Labyrinth.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (2nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.),

TUESDAY (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

WEDNESDAY (4th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (5th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (7th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Messrs. Armour and Co., Lond.; Messrs. Allen and Hoar, Lond.; Messrs. J. Archibald and Co., Hull; American Gynæcological Society, Washington; Mr. F. W. Alexander, Lond.

B.—Messrs. Blundell and Rigby, Lond.; Messrs. S. H. Benson, Lond.; Messrs. J. B. Brooks and Co., Birmingham; Bristol Royal Infirmary, Secretary of; Bristol General Hospital, Secretary of; Benger's Food, Manchester; Dr. J. S. Brown, Montclair, U.S.A.; Birmingham and Midland Ear and Throat Hospital, Secretary of; Mr. C. Boulangé, Paris; Mr. H. W. Bayly, Lond.; Messrs. Baillière, Tindall, and Cox, Lond.; The Bayer Co., Lond.; Dr. G. B. Buchanan, Glasgow; Brighton Corporation, Clerk to the; *Bryant Press*, Toronto, Secretary of; Mrs. Behnke, Lond.; Mr. W. J. Burroughs, Lond.; Mr. W. Boothman, Bradford; Mr. Haydn Brown, Caterham; Mr. H. Haward Bywater, Preston; Major H. Bolton, I.M.S., Lond.; British National Committee for International Congresses for Hygiene and Demography, Lond., Hon. Secretary of.

C.—Mr. F. W. Clarke, Chorlton-cum-Hardy; Mr. S. Combridge, Hove; Mr. Harrison Cripps, Lond.; Messrs. J. and A. Carter, Lond.; Continental Tyre and Rubber Co., Lond.; Coalexld, Lancaster, Secretary of; Chester County Asylum, Clerk to the; Messrs. T. Cook and Son, Lond.; Mr. H. L. Clark, Lond.; Messrs. Martin Clare and Co., Croydon.

D.—Mr. D. J. Duhig, Hornchurch; Messrs. F. Davidson and Co., Lond.; Mr. F. Diemer, Cairo; Mr. Leslie W. Dryland, Kettering.

E.—East-End Mothers' Lying-in Home, Lond.

F.—Dr. F. E. Fremantle, Lond.; Dr. R. F. Fox, Lond.; Messrs. Harvey Frost and Co., Lond.; Mr George P. Forrester, Darmstadt; Messrs. W. J. Fraser and Co., Lond.; F. R. H. M.

G.—Dr. Major Greenwood, Lond.; Mrs. N. E. Glanville, Lond.; Gloucester Royal Infirmary, Secretary of.

H.—Dr. R. H. Hodgson, Lond.; Dr. Joseph B. Howland, Boston; Dr. A. Harris, Southampton; Captain W. L. Harnett, I.M.S., Meerut; Mr. R. B. Hunt, Lond.; Messrs. T. H. Hewitt, Lond.; Messrs. C. J. Hewlett and Son, Lond.; Dr. R. G. Hebb, Lond.; Mr. Wm. Hamilton, Hove; Captain G. W. G. Hughes, R.A.M.C., Cairo.

I.—Invereden Sanatorium, Dairsie, Medical Superintendent of; Illinois State Board of Health, Springfield, Secretary of.

J.—Mr. G. P. James, Penarth; Mr. E. M. Judge, Chislehurst; Dr. W. Jackson, Nelson; J. M. P.

K.—Messrs. R. A. Knight and Co., Lond.; Professor E. Klein, Lond.; Mr. J. F. Kelsey, Arcachon; The Kny-Scheerer Co., New York.

L.—Dr. Thomas Lewis, Lond.; Dr. P. W. Latham, Cambridge; Messrs. Luzac and Co., Lond.; Leicester Infirmary, Secretary of.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

The Arris and Gale Lectures

ON

SOME EMBRYOLOGICAL PROBLEMS IN RELATION TO MEDICINE.

Delivered before the Royal College of Surgeons of England on Feb. 28th and March 2nd, 1910,

BY PETER THOMPSON, M.D. VICT.,
PROFESSOR OF ANATOMY IN THE UNIVERSITY OF BIRMINGHAM.

LECTURE I.

Delivered on Feb. 28th.

MR. PRESIDENT AND GENTLEMEN,—I should like to preface my lecture this afternoon by offering my thanks to the Council for the honour they have conferred upon me in appointing me to deliver two Arris and Gale lectures for the current year. I should also like to express my gratification on a point of more than passing interest to teachers of anatomy—namely, that the Council should have appointed two of those teachers to give the Arris and Gale lectures in successive years, those appointments coming after a period of over 30 years, during which, as Professor Elliot Smith noted in his first lecture in December last, no professed anatomist had held this lectureship.

RECONSTRUCTION METHOD.

In choosing a subject I came to the conclusion that as the advance in embryology in the last few years has been as great as that in many other scientific departments, and as this advance has been to a large extent the result of improved methods of research, you might be interested in hearing something of the mode of procedure by which embryologists are to-day endeavouring to unravel the earliest stages of development and particularly in seeing some of the results. By means of the reconstruction method in wax suggested by Professor Born it is now possible to visualise the various organs of the embryo, even when those organs are just laid down. Born's method, now well known and extensively utilised in this country, may be briefly described as follows.

The sections of the embryo are drawn on a thin sheet of paper either by the aid of a camera lucida or a projection apparatus and special drawing board, at a magnification of 25, 50, or 100 times the size of the section, as desired. Each sheet of paper is then placed on a stone, such as is used in lithographic work, and melted wax is poured over it. When partly solidified it is well rolled, the thickness of the wax being determined by two brass strips, one on either side of the sheet and either one-half millimetre or one millimetre in thickness, according to a calculation based on the thickness of the section and the magnification of the drawing. In this way wax plates are obtained from which the shape of each drawing can be readily cut by a sharp knife. These are all piled one on the other and when completed give a reproduction in wax of the form of the embryo magnified in accordance with the number arranged at the time of drawing. Many of the drawings on the screen have been made from models reconstructed in this way.

Everyone who works with serial sections knows how difficult it is to keep in mind the structures seen in each section so as to picture to himself the form of any part when entire, and still more difficult is it to convey to others the information which one has gained from working through such a series. By means of this kind of model, however, one is able to demonstrate the developmental condition of the various organs with the greatest ease, and consequently for teaching purposes they are invaluable. But in addition to this they enable us to be much more exact in our deductions, and they bring out, often with startling clearness, facts which would almost certainly be overlooked if the sections were simply observed by the worker and then a mental picture conceived of the condition of the parts.

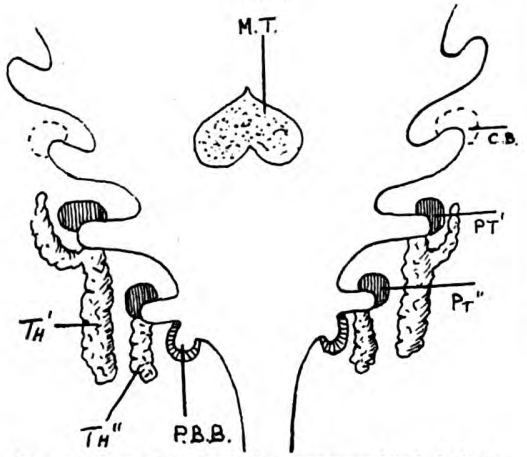
In the two lectures at my disposal I decided to take up the early stages of development of certain structures which must always have an added interest on account of their relation to medicine. A study of the early stages of the developing heart, the thyroid, and to a less extent the liver and lungs, brings out many points which have a practical significance and provides the key for certain problems which would otherwise remain unanswered. Most of these early stages are, of course, well known through the researches of a host of workers in this country and on the continent, foremost amongst which must be placed the immortal name of His. But having been fortunate enough to obtain three embryos, each in age under one month, and to reconstruct wholly two of these, and having access to other specimens which in age are intermediate, I am able to give a picture of the chief stages of the developmental history of the organs mentioned above up to the end of the first month, and to bring out, I hope, some points which will serve to make yet clearer our conception of what is going on in this eventful time.

I. THYROID BODY.

In order to understand the significance of the thyroid body in the adult, it will be advantageous if we first of all study the arrangement of the corresponding structure lower down in the vertebrate series. Let me say first of all that it will be necessary for us to deal separately with the median and the so-called lateral lobes, since in lower vertebrates these structures are independent throughout life. In nearly all fishes, and in amphibians, reptiles, and birds there is a median thyroid which develops from the floor of the mouth, and, in addition, a pair of outgrowths formed behind the last gill pouches, named the *supra-pericardial bodies* or *post branchial bodies*. In elasmobranch fishes, since they extend dorsally above the pericardium, the term supra-pericardial body is applicable, whilst in other forms they lie at the root of the trachea, and therefore some other designation is desirable. More recently the names "ultimo-branchial" and "telo-branchial" have been applied to these bodies.

Median thyroid.—In amphioxus the median thyroid retains its connexion with the foregut throughout life, and may be regarded as a gland accessory to the buccal cavity. According to Wiedersheim it discharges a sticky secretion which serves to unite the smaller food particles into larger masses, which are thereby prevented from being carried out with the stream of water through the gill slits. This function, as an important accessory in the taking in of food, becomes of less importance in the altered conditions of life in higher vertebrates. In the latter the connexion with the mouth cavity is lost at a very early stage of development and the gland embarks on a new career. It now consists of a mass of closed follicles which contain colloid.

The post-branchial bodies, as previously noted, are very widely distributed throughout the vertebrate series. They are not always bilateral, but in lower forms may be unilateral—a fact which has given rise to an interesting theory with regard to their morphology, to which I will refer shortly. Their function is practically unknown. To summarise the main points about them, it might be said that they are epithelial bodies, that in most vertebrates below mammals they never contain colloid, and that they never join with the median thyroid. In one of the lowliest of mammals, echidna, the post-branchial bodies contain colloid, but remain separate from the median thyroid. In other mammals, including man, the association between these bodies and the median thyroid is of a more intimate character. In the early stages of development, however, they are quite separate. (Fig. 1.)



Adverting to the absence of any knowledge of the function of the post-branchial bodies, the two following points seem worthy of notice. They are very close to the anterior end of the cœlom and the pro-nephros, and in this region in many lower vertebrates there is considerable accumulation of lymphoid tissue.

There are, at least, two views regarding the morphology of these interesting structures. In the one they are looked upon as derivations from a rudimentary gill-pouch placed behind the ordinary gill-pouches at the back of the pharynx, where it narrows to form the œsophagus; in the other, Maurer has suggested, particularly when unilateral, that such a body may be homologous with the œsophago-cutaneous passage which exists in certain fishes and in the myxinæ, for example, is only present on one side, the left.

In the light of the knowledge gained from a study of the comparative anatomy of the thyroid and post-branchial bodies we may turn to an examination of the development of the thyroid gland in man. Taking first the

median rudiment it is interesting to find that it is present as early as the third week of intra-uterine life (Fig. 2) and that at this stage it is in open communication with the anterior end of the fore-gut. It is placed dorsal to the aortic stem and only later when the head has grown more forwards is it placed ventral to that structure. In Ingall's embryo the second stage is seen; it is directed at first ventralwards towards the point of division of the aorta and then bends at

a right angle. The duct is still open and the lower end i bilobed, a condition resulting from a well-marked groove which appears on its deeper surface. In the third stage taken from an embryo of 28 days the condition of affairs is most suggestive. The duct has disappeared except for a short piece near the lower bifid end. This part of the duct and the gland attached to the end of it are still at right angles to each other. The thyroid itself is two-lobed, but the lobes are asymmetrical. The left is larger than the right, which is in a very rudimentary condition. From a reconstruction which

M.T., Median thyroid. × 50.

I made I came to the conclusion that the median thyroid in this case was formed largely from the left lobe. (Fig. 3.) The latter not only formed the left portion of the mass, but, extending across the middle line to the right, contributed largely to the right portion. The asymmetry of the two primary lobes and the subsequent formation of the bulk of the median thyroid out of the left lobe explains why the pyramid, when present, should be to the left of the middle line instead of median. Conversely, in those cases in which the right lobe is predominant one would expect to find any persistent pyramidal lobe to the right of the middle line.

The post-branchial bodies (lateral lobes of thyroid).—In Ingall's embryo of 4·9 mm. (i.e., end of third week) these bodies cannot with certainty be identified. A week later (i.e., in embryos of about 28 days and a length of about 7 mm.) the condition of parts is very satisfactory for studying a problem of great interest—namely, their relationship

to the pharynx. The fourth pouch is well developed, it is in contact over a considerable area with the bottom of the external gill-slit, and exhibits two divisions; of these, one is cephalad, the other caudad, whilst between the two runs the rudimentary fifth aortic arch. (Fig. 4.)

What is the significance of these two divisions? The cephalic division is well marked as a hollow diverticulum placed between the fourth and fifth aortic arches, and the question arises whether this may not give rise to a thymus metamere. I cannot from my own specimens supply the answer, but Groschuff has laid particular emphasis on the point that it may; and in drawing up my scheme of derivatives from the pharynx this occasional if not constant origin of a thymus must be considered. According to Groschuff

FIG. 4.

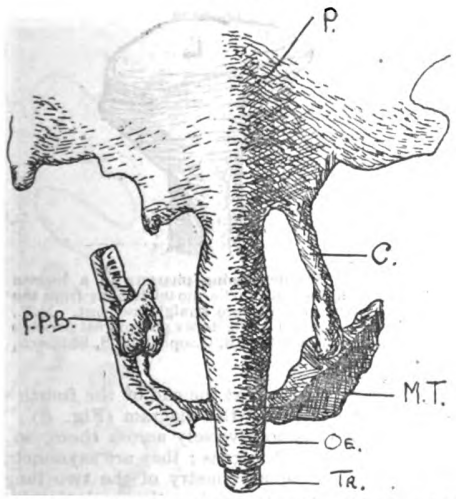
the outgrowth may persist in the adult as a parathymus, which either retains its independency (accessory thymus) or fuses with the parathyroid derived from the fourth pouch.

But it is with the caudal outgrowth that we are most concerned, since there seems little doubt that it is the representative in man of the post-branchial body of other vertebrates. It forms a wide diverticulum which extends caudalwards and opposite which is a shallow external depression of the ectoderm. Leaving out of consideration for the moment the debated question of lung origin, these bodies are truly post-branchial or ultimobranchial, connected on the one hand with the gut, and on the other hand directed outwards towards the ectoderm. But Elze has recently brought forward evidence regarding the morphological significance of these post-branchial bodies in the human embryo, and this evidence I am able to confirm

in almost every particular. According to Elze, what we are dealing with here is in reality a fifth branchial pouch, not necessarily the whole of the pouch, but a representative or derivative of a fifth pouch which has become rudimentary.



On what evidence is this conclusion based? It is this. That in the position of a fifth gill arch—i.e., immediately in front of and external to the post-branchial body—certain typical features are recognisable—namely, a rudimentary fifth aortic arch, a trematic branch of the vagus, and an external gill depression.

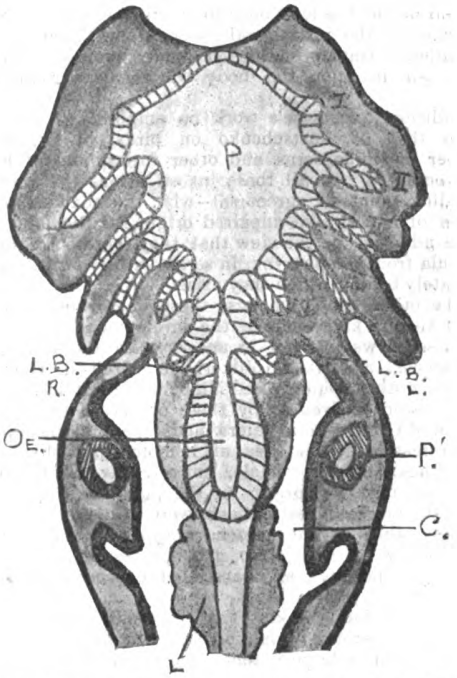
The view has also received striking confirmation by a research of Hammar, which Elze remarks seem decisively to settle the point. Hammar has described a human embryo of 5 mm. which possessed five developed pouches, all of which reached the ectoderm. The post-branchial body is represented as a bulging out from the fifth pouch.

Before leaving this question of the morphology of the post-branchial body a brief reference may be made to Greil's work on acanthias and anuren amphibia. He has conclusively proved that in these lower vertebrates the post-branchial body belongs to a rudimentary gill pouch, which no longer attains full development. The further history of the post-branchial body in the human embryo has been investigated, amongst others, by Verdun and Sudler, but before referring to their work I wish to call attention to the condition of the post-branchial body in monotremes.

In echidna, thanks to the work of Maurer, its history is well known; it contains colloid substance; it remains separate from the median thyroid. It is found at the side of the trachea, near the point at which it was originally laid down, whilst the median thyroid, accompanying the heart and great vessels, has shifted relatively backwards towards the thorax. In other mammals, also, the post-branchial body contains colloid, but, losing its independence, it becomes associated with the median thyroid to form a single structure. (Fig. 5.) How much it contributes to that body

FIG. 5.

Dorsal view of the pharyngeal region of a human embryo about 5½ weeks (Sudler). P., Pharynx. M.T., U-shaped median thyroid composed of isthmus and two lateral lobes. P.P.B., Post-branchial body (the so-called lateral thyroid) joining with the median thyroid; on the right side the connexion (C.) between the post-branchial body and the pharynx is still retained.



is a question which must for the present remain unsettled, but both Verdun and Sudler find that the lateral thyroid takes very little share in the formation of the adult organ. Indeed, according to Verdun, who bases his conclusions on an examination of the ox, cat, sheep, rabbit, antelope, and man, the thyroid in mammals is formed practically entirely from the median anlage, whilst the post-branchial body degenerates. This statement is in striking contrast with what Maurer has found in echidna, and it is, therefore, important that additional reconstructions of the thyroid in human embryos, at the early part of the second month, should be undertaken.

Accessory thyroid bodies.—The occasional existence of these bodies is well known, and the occurrence of enlargements of isolated masses of thyroid tissue has been frequently described by surgeons. Perhaps those best known occur somewhere in the track along which the median anlage has descended during its ontogeny. But a second group may arise in a somewhat different way. The median thyroid enlarges by lateral sprouts, and apparently one or more of these may become detached from the rest of the gland. The shifting backwards, in a relative sense, which subsequently occurs in connexion with the main mass, may leave these detached bodies behind, and as the third pair of aortic arches straighten out to form the internal carotids they may become closely associated with them. In this way one may explain the occurrence of isolated masses of thyroid tissue in the region of the upper part of the neck, and in the neighbourhood of the angle of the jaw, which have become enlarged and subsequently removed.

II. LUNG BUDS.

I come now to consider the question of the mode of origin of the lung buds. To von Baer, who in 1828 published the first volume of his great work entitled, "Observations and Reflections on the Development of Animals," we owe the first description of the development of the pulmonary apparatus. In that volume von Baer describes in the chick two small hollow

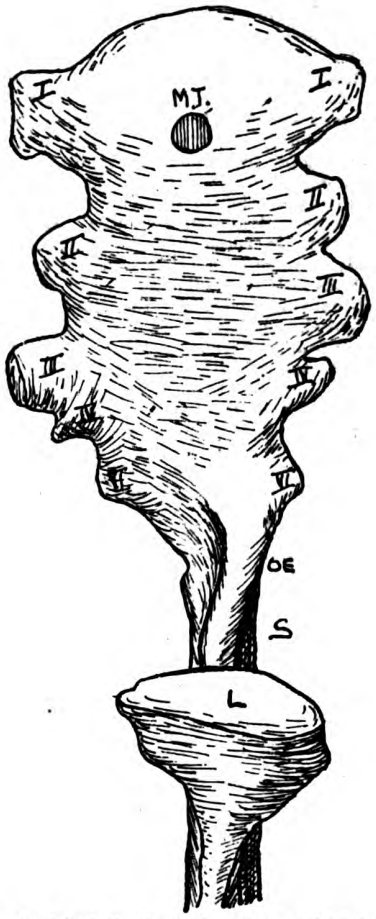
FIG. 6.

The development of the lungs in the frog (Goette). P., Pharynx. I to V, One to five pharyngeal pouches. L.B.R. and L.B.L., right and left lung buds. OE., Œsophagus. P'., Pronephros. C., Cœlom. L., Liver.

swellings about the middle of the fore-gut, which appear on the third day. A day or two later the trachea is distinguishable as a short canal, which soon separates off from the dorsally placed œsophagus, except in front, where the two tubes remain in communication one with the other. From that time down to the present those who have worked in this field fall mainly into two groups. In the one the view that the lungs are primitively paired structures and appear before the demarcation of the trachea, as von Baer found, receives fairly wide, but by no means convincing, support. In the other the observers are for the most part agreed that the respiratory apparatus is derived from a median unpaired structure, which at the caudal end subsequently divides into two buds the rudiments of the lungs. Corresponding with these two views of mode of development are two conceptions of the morphology of the lungs. On the one hand, we have the idea that the primitively paired structures are in

serial homology with the gill pouches; and on the other, that the median unpaired structure, which represents the trachea and the caudal end of which soon becomes bi-lobed to form the lungs, is the homologue of the swim bladder in fishes.

I have not the time in this lecture to go farther into the history of the subject, nor, indeed, is there any need. Those of you who wish for further details will find a most comprehensive paper by Dr. Marshall Flint of the University of California dealing with the whole question of lung development in the *American Journal of Anatomy* for 1906–07. The attempt to bring lungs and swim bladder into phylogenetic relationship has not up to the present time been very satisfactory. The difficulties are many. It is well known, for example, that the swim bladder may be either single or paired—rarely the latter; that it is a hydrostatic organ to enable the fish to rise and sink in the water; that in ganoids and especially in dipnoan fish it can take on the functions of respiration, and that it may arise either from the dorsal or the ventral wall of the fore-gut, but most frequently from the dorsal. It is not surprising, therefore, that evidence in favour of associating the lung buds with other outgrowths from the pharynx has been steadily accumulating, and quite a number of observers incline to the view that they are in serial homology with the gill pouches. May I direct your attention to this diagram of Goette (Fig. 6) which shows the origin of the lungs in an amphibian. The resemblance to the gill pouches is very striking and the inference is irresistible. Goette sums up the matter thus: "In their origin the lung buds in anura completely resemble the anlagen of the pharyngeal pouches, and therefore are to be regarded as transformations of such pouches which have been drawn in from the body wall and surrounded by cœlom."



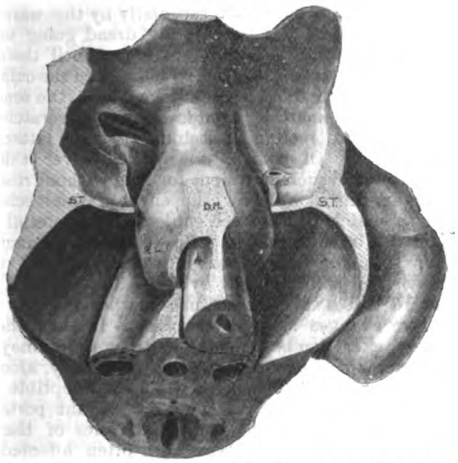
In addition to Goette's work on amphibia, I must also mention that of Kastschenko on birds, of Weber and Buvignier on minopterus and other forms, and of Fol on human embryos. In all these investigations there are two outstanding points of agreement—viz., the abandonment of the idea of a primitive unpaired origin for the lung buds, and the adoption of the view that they represent a pair of diverticula from the pharynx, in series with the gill pouches, immediately behind which they arise.

On the other hand, amongst those whose work has contributed to our knowledge of the development of the lungs, and whose views are not in accord with the conclusions stated above, are His, Kölliker, and Greil in Germany, Robinson in this country, and Minot and Flint in America. The conclusions arrived at by these observers are (with the exception of Greil, who in anura finds the lung buds paired but disagrees with the idea of homologising them with gill pouches), on the whole, entirely favourable to the view of an unpaired origin for the pulmonary apparatus, and Flint, whose investigations were made on the pig, concludes "that if the pulmonary apparatus in mammals should finally be shown to have a serial relationship with the gill pouches, all trace of the process is lost in the pig."

Now I cannot help thinking that the main reason for this sharp line of difference of opinion regarding the origin of the lungs depends to a large extent upon the fact that the two processes—(1) evagination of buds and (2) division of tube—tend from the very beginning to proceed simultaneously, and that sometimes the one and sometimes the other is in advance. Undoubtedly the lung buds may be post-tracheal or the trachea may be post-pulmonary in time of origin, or the two processes may synchronise at the start. But the observation repeatedly made that the buds can and do appear first is important evidence, and whilst not proving their homology with the gill pouches, goes far in support of that contention.

Let me turn now to describe two models which I have here on the table, and which illustrate two stages in the development of the lungs. In the one the lungs are seen in the third week, and in the other at the end of the fourth week. In the former (Fig. 7) it will be noticed that the pharynx is wide from side to side, flattened dorso-ventrally, and has a series of four pouches on each side. The pharynx is succeeded by a very short piece which joins it to the stomach. This represents the œsophagus, and the arrangement of this part of the tube is worth special attention. Although it is so extraordinarily short it manages to change the direction of its long axis, so that whilst at its commencement this is transverse, at its termination it is antero-posterior. The lung buds are just visible as two small outgrowths behind the last pair of pouches, and on account of the rapid change in the direction of the long axis the two buds are in different planes, one being behind and to the right and the other in front and to the left.

FIG. 7.



View of a model of the developing pharynx in a human embryo 2·5 millimetres long. The model is seen from the front and is drawn as if it were straightened out. M.T., Median thyroid. I. to VI., One to six pharyngeal pouches (fifth pouch not yet formed). OE, Œsophagus. S, Stomach. L, Liver.

This disposition of the buds at the end of the fourth week is seen in the model and in the diagram (Fig. 8). The septum transversum runs transversely across them, so that they are in part abdominal organs; they are asymmetrical, already foreshadowing the asymmetry of the two lungs in the adult, and they have an interesting relationship to mesenteries.

The dorsal mesocardium originally connected with the under aspect of the pharynx is, with the formation of the respiratory system, fixed to the latter at the point which corresponds to the bifurcation of the trachea, and it is between the two layers of this fold that the pulmonary veins grow from the lung buds to the heart. Subsequently the dorsal mesocardium disappears. But in the drawing of the 7 mm. embryo you will notice that it is continuous at this stage, as in the 2·5 mm. embryo, with the septum transversum, the structure which will form a part—the central tendon—of the diaphragm. Below the septum transversum the right lung bud also has a mesenteric fold attached to it. It is known as the "caval mesentery," or better, the "plica venæ cavæ," for the reason that when it is traced caudalwards it is continuous with a fold in which the earliest sign of the inferior vena cava is found.

The caval mesentery is really a special development of the dorsal mesogastrium, at first bilateral but which with the displacement of the stomach to the left disappears on that side and becomes prominent on the right. The caval mesentery unites right lung bud to liver and posterior body

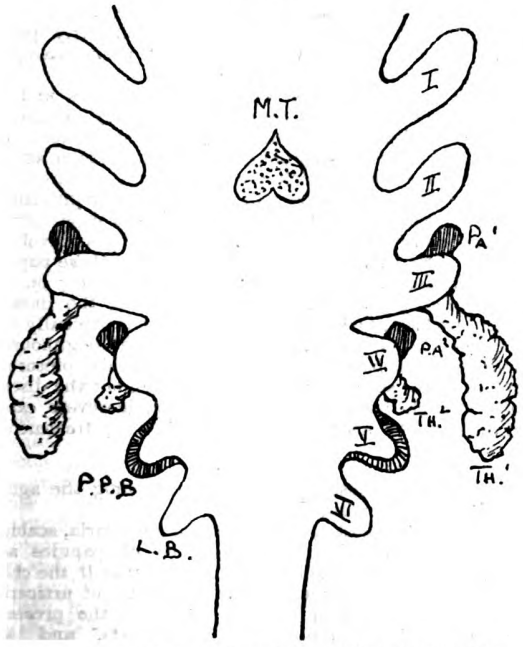


FIG. 8.

The posterior body wall of a human embryo about 28 days. The position of the diaphragm is shown by the line (interrupted in the middle) running transversely from S.T. to S.T. The lung buds, right and left (R.L. and L.L.) are seen to be partly thoracic and partly abdominal in position. D.M., Dorsal mesocardium. The arrow points upwards to the peri-œsophageal cœlom. × 25.

wall to liver and its hepatic attachments are clearly seen by a reference to one of the diagrams of the liver (Lecture II.). It occupies the ground which will subsequently be taken by the inferior vena cava, and probably the

FIG. 9.

Schema of the pharyngeal pouches and their derivatives in the human embryo. M.T., Median thyroid. I to VI, One to six pharyngeal pouches. TH[1] and TH[2], Thymus rudiments. PA[1] and PA[2], Parathyroids. P.P.B., Post-branchial body (rudimentary fifth pouch). L.B., Lung bud, representing a sixth pouch.

main reason for its existence is to provide the track along which the inferior vena cava may extend across the back of the liver. In rabbit embryos, according to F. T. Lewis, the fate of the caval mesentery is briefly this. It forms more than a nidus for the laying down of the inferior vena cava, since the part most cephalad is invaded by the right lung, of which it forms the lobus inferior medialis of Krause. Lower down it meets and unites with the liver, hepatic tubules grow into it, and it becomes a part of the liver.

SCHEMA OF PHARYNGEAL POUCHES.

If we regard the post-branchial bodies (lateral thyroids) as representing rudimentary fifth pharyngeal pouches (Fig. 9), and the lung buds as representing pharyngeal pouches also, arising behind them, then we can construct a schema of such pouches in the human embryo, which shows six pairs in all. But it should be clearly understood that there is normally no period in the human embryo in which there are at one and the same time six clearly recognisable pouches in connexion with the gut on each side. In the diagram shown of the 2·5 mm. embryo (Fig. 7), there are clearly five pouches present, the rudimentary fifth having not yet formed. At the end of a month—i.e., in the 7 mm. embryo—all the pouches are recognisable, but the sixth or pulmonary now appears at the end of the trachea.

It is interesting and significant that six pairs of aortic arches are developed in the human embryo as in some other mammals, and that the fifth should be so transitory and leave no vessel, as far as is known at present, derived from it. This is in conformity with the rudimentary nature of the fifth pouch, whilst in connexion with the sixth pair of arches the pulmonary arteries are developed and are distributed to the lungs, organs phylogenetically related either to the gill-pouches or to the swim-bladder.[1]

A Clinical Lecture

ON

ITCHING DISEASES OF THE SKIN AND THEIR TREATMENT.

Delivered at the Medical Graduates' College and Polyclinic on March 17th, 1910,

BY J. L. BUNCH, D.Sc., M.D. LOND., M.R.C.P. LOND.,

PHYSICIAN IN CHARGE OF THE SKIN DEPARTMENT, QUEEN'S HOSPITAL FOR CHILDREN, LONDON; MEMBRE CORRESPONDANT DE LA SOCIÉTÉ FRANÇAISE DE DERMATOLOGIE.

GENTLEMEN,—To the practitioner there are no more unsatisfactory cases, to the patient there are few diseases which cause greater discomfort, than itching eruptions of the skin. Whether the case be one of pruritus, eczema, urticaria, lichen planus, scabies, or other affection of the skin, the constant irritation, restlessness, discomfort, and want of sleep are a source of worry and anxiety which soon tell upon the patient's temper and general health, and in many cases drive him almost to despair, and occasionally, in neurotic individuals, even to self-destruction.

CLASSIFICATION.

To the student unnecessary difficulties are presented by the inability of different dermatological schools to agree upon a simple nomenclature or classification of the itching diseases of the skin, and it is not only the student who is sometimes in doubt whether pruritus is a symptom or a disease, and how it is related to, or differs from, prurigo. To speak of an itching skin lesion as "pruriginous" is only to complicate matters still further; indeed, in my opinion, the use of the adjective in this sense is entirely unjustifiable.

The view which I personally hold, and which is held by the chief French dermatologists (especially Brocq and Darier), is that pruritus and prurigo are diseases in which itching is the primary factor, and which differ from one

[1] In a paper "On Certain Features in the Development of the Alimentary Canal in Lepidosiren and Protopterus," published in the *Quarterly Journal of Microscopical Science*, February, 1910, Professor Graham Kerr says "that he feels compelled to accept the general homology of the organs known in various subdivisions of the vertebrata under the name of lung and swim-bladder or air-bladder." In this paper Professor Kerr brings forward evidence to show that migration of the air duct from a ventral to a dorsal position may take place.

another only in the fact that in prurigo the scratching gives rise to certain cutaneous reactions in the form of papules or lichenification. I repeat that in prurigo, as in pruritus, itching is the primary phenomenon, and that prurigo is pruritus accompanied by certain definite lesions of the skin which are brought about by scratching. This definition makes the differential diagnosis between the two affections quite easy, it clears the ground of all misapprehensions, and makes it clear that the itching is the primary affection and the skin lesions entirely secondary.

In pruritus, as distinguished from prurigo, some traumatic lesions may be brought about by scratching, such as pus infection, impetigo contagiosa, and secondary eczema, but there are no prurigo papules and no lichenification. Inasmuch as in prurigo the itching is primary, this forms a distinction from those cases of eczema which become lichenified and therefore come to resemble an eczematised prurigo. A secondary prurigo may of course arise, just as a secondary pruritus may and does exist.

ETIOLOGY.

It has been argued that itching is not necessarily pathological, that the brushing of a hairy portion of skin lightly with a feather gives rise to intense itching which persists for some time when the stimulus is removed, and that there are special nerve endings and end organs for this sensation, as there are for the sensations of pressure, touch, heat, and cold. But that these end organs can be centrally stimulated and itching arise from a disturbance of the central nervous system alone has never been demonstrated, and we are fully justified in maintaining that a peripheral stimulus is necessary. The commonest peripheral stimuli causing pruritus are the bites of insects, such as fleas, and many vegetable and chemical substances. Want of cleanliness is of itself a sufficient stimulus to many skins, and when combined, as it so often is, with other sources of irritation, acts as a powerful factor to intensify their action.

Secondary pruritus is, of course, common in many dermatoses, such as eczema, lichen planus, scabies, urticaria, mycosis fungoides, and the dermatitis of Duhring. In such cases it follows or accompanies the outbreak of the skin lesion, and there can be no question of the sequence. Some diseases are, of course, never itchy, such as lupus, syphilis, and psoriasis.

Primary pruritus is a functional affection of the skin, the sole symptom of which is the subjective sensation of itching. The skin appears healthy and shows no pathological changes to which we can point as a cause for the irritation. Such pruritus occurs in neurasthenia, chorea, and excessive emotion, and may perhaps be ascribed to an over excitability of the special end organs in the skin, if not to an ill-defined auto-intoxication. Such an auto-intoxication does undoubtedly cause pruritus in diabetes, uræmia, gout, and jaundice. The same effect is produced by subcutaneous injections of morphia when these are repeated too frequently or in too large doses; excessive doses of belladonna also have much the same action. It is well known that certain kinds of food and articles of diet greatly aggravate any pruritus or may even give rise to an attack, especially sugars, malt liquors, coffee, and some kinds of tinned fish. In all these cases the poison is circulating in the blood stream, and diffuses thence into the lymph which is in contact with the nerve endings in the skin, so that these are directly attacked by the toxic substance.

Other etiological factors are excess of any kind, whether mental or physical; depression, whether preceded or not by over-excitement; and a neurotic taint. Rapid changes of temperature or pressure often bring on an attack in predisposed individuals. Thus, there is a well-known form of summer pruritus, and some individuals who work exposed to high temperature are especially liable to pruritus; in others a draught or stream of cold air has the same effect. Many women experience itching when at night they remove articles of clothing which have caused pressure, such as corsets, garters, or tight shoes, and this is almost certainly due to dilatation of the capillaries of the skin following the prolonged constriction to which they have been subjected during the day. The vaso-motor disturbance is only a temporary one and soon passes off, but the pruritus may persist for an hour or more.

CLINICAL VARIETIES.

The clinical varieties met with may be divided into (1) generalised and (2) local. Of the two, generalised pruritus is far the more troublesome and may make life absolutely unbearable to the sufferer. The itching is not continuous but comes on in spasms, during which the patient cannot possibly refrain from scratching and may tear his skin almost to pieces, using not only his nails but any instrument he can find which seems to promise relief. These attacks are brought on especially by the warmth of bed, so that many patients absolutely dread going to bed, knowing that they will be unable to sleep until their continued and forcible scratching has so benumbed the cutaneous nerves that they fail to respond any longer to the sensation of pruritus, or the smarting produced by their scratches has so overpowered the feeling of itching that the latter is no longer perceived. Of course, no skin, however thick or resistant, can stand such treatment for long without resenting it, and it soon begins to show the effect of the mechanical irritation to which it has been subjected. Bacterial infection is added before long and impetigo, ecthyma, furunculosis, and other staphylococcal diseases are superadded to the abrasions of the skin wrought by the patient's nails. The most severe cases are those in old persons in whom degenerative changes have taken place. In them the skin becomes dry, excretion is deficient both by the kidneys and the skin, and toxic substances, whether of a gouty, alcoholic, or other nature, act readily upon a dry and susceptible skin.

Local pruritus may involve the most distant portions of the skin. The palms of the hands and soles of the feet, especially in hyperidrotic persons, are often affected, and pruritus of the nose is not uncommon. But pruritus of the genitals is much more troublesome—in men, of the scrotum and anus, and in women, of the vulva.

The itching is usually intense, especially at night, and leads to agonised scratching and its usual consequences—thickening of the skin and mucous membrane. Kraurosis vulvæ comes to be simulated in women, especially in diabetic patients, where the sugar-containing urine acts as a continual source of irritation. In such cases the mucous membrane of the vulval orifice is dry and irritable, the epithelium having a glazed, whitish appearance accompanied by atrophic changes, and no treatment short of excision of the affected strip of mucous membrane can relieve the itching. Uterine discharges, diseases of the rectum, such as hæmorrhoids, fissure, or carcinoma, are similarly potent factors, and bring about a condition which cannot easily be distinguished from a primary chronic eczema.

Prurigo is an itching eruption, not contagious and not hereditary, starting in most cases in early infancy. It may be defined as pruritus *plus* papular or lichenified lesions of the skin. The itching is the primary factor, but is soon accompanied by an eruption which presents all the picture of an urticaria. This consists of small papules, pale or pinkish, at first only perceptible to the touch, distributed especially on the exterior surfaces of the legs and arms, but also involving the trunk. Under the influence of scratching these papules become inflamed, excoriated, and crusted. Later on the skin becomes pigmented, dry, and thickened, the lines of the skin are deepened, and the appearance is typically that of "lichenification" of the affected area. The neighbouring lymphatic glands become enlarged. The clinical picture is complete by the second or third year of life, but the disease usually persists for many years, or even, in severe cases, until the patient's death, influenced but little by treatment.

DIAGNOSIS.

In making a diagnosis of the cause of itching the age of the patient is an important factor.

In *children*, the most common causes are urticaria, scabies, pediculi, and ascarides. The presence of papules and wheals, the history of the lesions appearing "as if the child had been stung with a nettle," are diagnostic of urticaria, while the distribution of a scabies eruption, the presence of "burrows" on the hands and wrists, and the identification of the acarus leave no room for doubt. Thread-worms are a frequent cause of pruritus ani in children, and when these have been got rid of the itching will be found to disappear.

In *adults*, especially among the poorer classes, scabies is also a very common cause of itching. The lesions are vesicular, pustular, or occasionally bullous, irregularly grouped, extending from the sternum to the knees in front, and posteriorly involving the buttocks and lower part of the

back. Between the fingers, on the wrists and umbilicus, numerous small vesicles are intermingled with the typical dirty track or burrow along which the acarus has made its way after entering the epidermis. This burrow contains the eggs and excrement, and at the distal end the acarus itself, which may be made out with a lens as a greyish pearly body. On the proximal side of the acarus is often a small vesicle, and in extracting the acarus it is wise not to open this vesicle. It is only the female acarus which is found in a burrow, and it remains there until its death, a period of a month or two, depositing eggs which become hatched out as the oldest are brought nearer the surface by the fraying away of the superficial layers of the epidermis. With the point of a needle it is easy to pick out the acarus, or the burrow may be excised entire for the purposes of diagnosis with a tenotomy knife, or even the demonstration of the presence of the ova is sufficient proof of the nature of the disease. In addition to the essential lesions of scabies there are usually numerous secondary lesions, partly scratch marks, partly due to staphylococcal infection superadded. Ruptured vesicles, scabbed patches, and superficial hæmorrhagic lesions are distributed irregularly over the trunk and arms, but the face is very seldom affected.

Although, of course, destruction of all the acari and eggs necessarily cures scabies, patients often complain of itching for some time afterwards, and one has seen mentally unstable patients who maintain that they still have scabies years after they have been cured. But these are rather cases of scabies of the brain than of the skin. In other persons the itching persists because the sulphur or other substance used to kill the acari has, through being used for too long a time, set up a dermatitis which is hardly less irritating than the original disease.

Urticaria is also a cause of itching in adults; eczema, of course, is only too common, but perhaps the two diseases which may cause the most intense itching are the less common affections of the skin, mycosis fungoides and lichen planus. Only recently I showed here the case of a man with mycosis fungoides whose life was made absolutely miserable by the irritation, not only when the disease was fully developed and there were fungating tumours, but also in the premycotic stage when there was only an ill-defined pinkish dermatitis. Similarly in lichen planus the itching may be intolerable, especially in patients who are highly strung neurotic, or neurasthenic. The small number of papules and the apparent slight intensity of the lesions seem to be no criterion of the amount of irritation which they suffer, and the consequent insomnia and want of rest may have a most serious effect on their general health, leading even to suicide.

In adult patients suffering from pruritus, when no signs of pediculi, scabies, lichen planus, or other skin lesions can be found, it is most important to examine the urine for sugar. The onset of diabetes in many patients is very insidious, and one of the earliest symptoms may be a passing attack of pruritus which is at first relieved by a sedative application, only to recur in more severe form when the diabetes has thoroughly undermined the patient's health. This might have been avoided and the disease checked or cured if sugar had been found at first and a strict diet ordered.

In *old* persons any of the previously mentioned causes of pruritus may occur, but there is a cause of itching which is almost peculiar to them, and that is phthiriasis. That it occurs among the poor and neglected is of course well known, but even among the well-to-do it is not uncommon. Many people of advanced age become careless of personal cleanliness and appear to have a strong disinclination to baths. Moreover, they feel a greater need of warmth than the young and strong, and frequently sleep in their vest under their night attire, so the pediculi are a source of irritation both by day and night. In such individuals the skin is dry and deficient in secretion, and appears to be especially susceptible to the attacks of the insect. The scratch marks are at first most marked on the shoulders and upper part of the back and chest, but may become generalised, and are intermingled with the hæmorrhagic points caused by the bites of the pediculi.

TREATMENT.

Before deciding on the treatment appropriate to any case it is necessary to determine whether it is one of primary or secondary pruritus. No case can be regarded as a true primary pruritus until all possible causes of external irritation have been eliminated. If after very careful examination no such causes can be found, inquiries must be made as to how far the patient's mode of life transgresses the usual hygienic principles and whether there is any evidence of diabetes, gout, or intestinal disease, as shown by investigation of the urine and blood and general physical examination. Any circumstances which might predispose to, or determine the onset of, pruritus must be inquired into, and the patient's diet and mode of life regulated accordingly. In almost every case alcohol, tea, and coffee must be forbidden, also rich and highly seasoned dishes. Some patients find relief from a vegetarian diet with plenty of milk, or, in default of this, they should live chiefly on poultry, green vegetables, and milk puddings, with plenty of Salutaris or slightly alkaline mineral waters. Rest and absence of worry have a favourable effect on neurotic patients, and it is often wonderful how much good a few weeks in bed or in a nursing home will do. Some pruritics are benefited by a change to the country or the mountains, or to a spa like Royat or Aix-les-Bains.

Internal treatment should begin by giving preparations of salicylic acid; salol, sodium salicylate, and salophen may be given alone or in combination with antipyrin or antifebrin or phenacetin. Carbolic acid in pill form is successful in some cases, arsenic and atropine may be tried, and pilocarpine (10–20 drops of a 1 per cent. solution) occasionally gives good results. But greater success is usually obtained with sedatives, especially bromide of sodium in combination with cannabis indica, or tincture of aconite with tincture of gelsemium. In more severe cases where insomnia is a marked symptom hypnotics are necessary—sulphonal, trional, chloral hydrate, or medinal.

External treatment must, however, always be employed in addition to internal remedies, and one of the simplest and most effectual applications is an evaporating lotion. Equal quantities of eau-de-Cologne and water applied on lint, which is kept moist with the liquid, or lavender water dabbed on every few minutes, often afford great relief, especially if preceded by hot applications. Sponging with hot water, as hot as can be borne, with or without the addition of bicarbonate of soda, or a hot bath, or better still a vapour or Turkish bath, causes dilatation of the capillaries of the skin, and the subsequent constriction of these vessels caused by cooling or evaporating lotions is not only more complete, but also induces a more lasting cessation of the itching. The addition to a hot bath of oatmeal is usually beneficial; or, still better, half a pound of gelatine made into a jelly with warm water and then added to the bath; or one pound of starch worked into a smooth paste with cold water and boiled, or half to one pound of linseed. Creosote and sulphurated potash are somewhat objectionable to sensitive patients, but the sulphaqua powders are a convenient method of making a sulphur bath which is not unpleasant. A combination of sulphur and pine oil bath is obtained by dissolving piutinol in the bath, and it gives good results. Of cooling lotions the simplest is one containing 2 drachms of liquor plumbi subacetatis to 1 ounce of lavender water and 7 ounces of distilled water. One containing hydrocyanic acid, which is very successful, is the following: dilute hydrocyanic acid ℥iss., spirit of rosemary ℥i., glycerine ℥ss., water to ℥x. Carbolic acid made up in the strength of ℥i. to ℥x. of water, with the addition of ℥ss. glycerine and ℥ss. eau-de-Cologne, gives a useful lotion, and, if necessary, to any of these lotions ℥ii. of cocaine may be added to give a greater anti-pruritic effect.

The best way to apply these lotions is to soak a single layer of lint or linen with the lotion, lay it lightly on the itching surface with no covering over it, and sprinkle or spray on fresh lotion every five minutes so as to keep the lint thoroughly moist.

Alkaline lotions, consisting of either ℥ii. bicarbonate of soda, ℥ii. carbonate of potash, or ℥i. borax to ℥viii. water, are all useful for cases where large areas of skin are involved, and the addition of a little menthol will increase the effect. Ichthyol ℥ss., sodium bicarbonate ℥iss., spirit of lavender ℥ss., water to ℥viii., is a lotion which often gives relief and may be used for weeks without harmful effects.

For general pruritus, ointments, sprays, paints, and varnishes are rarely suitable, but they all find their uses in

the localised forms of pruritus of which I am now about to speak.

In pruritus genitalium, and especially pruritus of the vulva, the hygienic and dietetic rules, already discussed in detail, must be adhered to. In the more usual cases of pruritus vulvæ, where there is a uterine or vaginal discharge, strict cleanliness must be enjoined with plentiful use of soap and water and douches of 1 in 5000 potassium permanganate or 1 in 5000 perchloride or 1 in 1000 zinc sulphate. After this a vaginal tampon must be inserted and the external parts covered with Lassar's paste containing 1 per cent. silver nitrate or lenigallol. An ichthyol ointment or paste may be substituted or an ointment containing 30 minims of chloroform to 2 ounces of lard, or the ordinary aconitine ointment. An ointment which often gives good results is the following: chloral hydrate, menthol, and camphor āā gr. 45, lanolin and vaseline āā ʒss. The advantage of using an ointment is that the parts are protected from the action of any discharge which, in spite of the tampon, comes in contact with them. In my experience fluid solutions of menthol or carbolic acid usually cause intense smarting and soreness in these cases, and so do many spirit applications. The addition of cocaine in the strength of 5 per cent. is often advantageous and may be combined with oil of cade or anthrasol in the form of an ointment.

The more inveterate cases respond well to applications of a Paquelin cautery, to excision of kraurotic skin areas, or to turning up a flap of skin all round the vulva, and division of the afferent nerve fibres. In cases of diabetes the patient must be strictly dieted, and, if the urine cannot be always drawn off with a catheter, the vulva should be covered with some protective sedative dressing in the form of an ointment or soluble varnish. One of the best of these latter is unguentum casein with the addition of 2 per cent. ichthyol or 1 per cent. tar. Casein ointment is composed of alkali caseinate, glycerine, vaseline, and water, and forms a thick white emulsion which dries on the skin in a minute or two, forming an elastic, dry covering, which is readily washed off. On the one hand, it is porous enough to permit of evaporation; on the other, it contains fat which helps the added ichthyol or tar to make its way deeply into the tissues. It is therefore more than a protective varnish, and holds a position intermediate between the ointments on the one hand and the pastes and powders on the other. Methylene blue given in pill form, one grain night and morning, with a paint of methylene blue, four grains to the ounce, applied at frequent intervals, has the objection that it stains the urine blue, but if this does not contain sugar the treatment is often successful.

Pruritus of the anus is usually accompanied by some secondary eczema with the formation of rhagades and thickening of the skin. This thickening must first be got rid of, either by 3–5 per cent. salicylic ointments and plasters, or by daily applications of diachylon ointment. When the induration has diminished, the rhagades and excoriations have healed, and any hæmorrhoids present have been removed, an ointment of liq. carb. det. ʒss. to ung. conii ʒi. will relieve the itching. Or creosote ʒss., tinct. aconiti ♏x., adipis ʒi.; or tinct. aconiti ♏iii., zinci oxidi ʒss., calomelanos ʒss., ol. rosmarin. ♏x., vaselin. alb. ʒi. These ointments are best used at night, bathed off in the morning with some olive oil, and the following powder applied: chloral hydrate, camphor āā gr. 40, starch ʒi. A 20 per cent. solution of ichthyol painted on frequently gives relief, and I prescribe with success this paint: ol. cadini ʒi., spt. coloniensis ʒss., aq. dist. ʒi., tinct. quillaiæ q.s. ut fiat emuls. Equal quantities of lime-water and black wash make an excellent application, or chloroform ʒi. to sweet almond oil ʒi., followed by a zinc oxide and calamine powder. Small enemata of half a drachm of medinal to an ounce of water, or 5 per cent. ichthyol in very hot water, may be alternated with suppositories of cocaine, morphia, or medinal, taking care that there is a regular action of the bowels at least once a day.

While speaking of suppositories, I do not wish to be taken as recommending morphia and cocaine suppositories to be taken regularly over long periods of time; indeed, I discontinue their use in any particular case as soon as possible; but as a temporary measure they are to my mind of the greatest service. It must be remembered that many patients scratch quite unconsciously during their sleep until the cutaneous nerves have been numbed by the vaso-motor dilatation and exudation. And this in spite of any dressings which may be applied unless they are fixed very tightly in position. Such scratching may undo the whole benefit of the treatment employed during the day, and leave an excoriated and inflamed surface which takes some time to heal up. The dry skin of the aged is especially susceptible to such ill-treatment, and these patients also sleep less soundly than the young and robust. In such cases I do not hesitate to give morphia or other suppositories, at any rate when they first come under treatment, with the greatest benefit to the patient.

In the most obstinate cases a rapid application of the actual cautery to the most irritating areas often causes great amelioration of the symptoms. Application of the high frequency current with a glass electrode is occasionally successful, and cases frequently react well to two or three ½ pastille doses of X rays at intervals of a week. The action of X rays on pruritus is not easy to explain, but I have seen cases which resisted all other treatment cured, at least for a time, by this means.

A more permanent cure, and one to be recommended in those intense cases when life has become a misery, is that of surgical operation. Such operations all aim at division of the cutaneous afferent nerves, and if this is done the area supplied is, of course, rendered temporarily anæsthetic. Sensation recurs in from three weeks to a month, but the pruritus does not return for years, if at all, in that area. In Ball's operation incisions are made on either side of the anus and flaps are turned up, leaving a small pedicle of skin which is undercut, as also is the skin in an outward direction. The flaps are separated up to the white line, but the hæmorrhoidal vessels are only slightly interfered with, so that there is no sloughing. The results of this operation are excellent, and for really serious cases it may be strongly recommended.

Time does not permit of my dealing with the treatment of all the diseases of the skin individually which are accompanied by itching, and I need only say that the treatment in every case must be primarily that of the skin disease and only secondarily that of the pruritic symptoms. In mycosis fungoides and some cases of lichen planus these symptoms may be so severe as to overshadow everything else, and under these circumstances it is necessary to resort to some of the principles and remedies which I have already fully discussed under the heading of pruritus. And by the choice of suitable treatment and attention to detail success will be attained, rather than by the employment of the latest and most extensively advertised new drug.

UNIVERSITY OF SHEFFIELD.—The Council at its last meeting made the following appointment: Mr. Alexander Wilson, M.B., Ch.B. Aberd., to the post of demonstrator in anatomy. The Council received the following resignation: Mr. A. Garrick Wilson, F.R.C.S. Eng., as honorary demonstrator in anatomy, in consequence of his appointment to the tutorship in surgery in the University. Mr. H. K. Stephenson was appointed representative of the University on the West Riding County Association.

PRESENTATIONS TO MEDICAL MEN.—Mr. James Waterston, L.R.C.S. Edin., who is the oldest medical practitioner in Sunderland, has been presented with an illuminated address, a specially designed arm-chair, and a smoker's outfit from the staff and committee of the Sunderland Provident Dispensary. Mr. Waterston is one of the medical officers connected with the institution, and for 14 years occupied the position of vice-chairman. For the past 14 years he has acted as chairman.—Mr. W. H. M. Barclay, M.B., C.M. Edin., who is Provost of Grantown, was on April 23rd presented by his patients and friends with a handsome motor-car and a cheque for £241 in recognition of his faithful and untiring services as a medical man in the town and wide district over which his patients are scattered. Mrs. Barclay was also presented with a silver salver bearing the inscription: "Presented to Mrs. Barclay on the occasion of the presenting of a motor-car to Dr. William Barclay, Provost of Grantown-on-Spey, as a tribute of public esteem and in recognition and appreciation of his public services and self-sacrificing labours as a trusted and skilful physician doing 30 years' strenuous professional work in Strathspey. April 25th, 1910."

THE PRACTICE OF WASSERMANN'S REACTION FROM THE QUANTITATIVE STANDPOINT.

BY BERNARD KLEIN, B.A., M.B. OXON.

THE object of this paper is to describe the examination of cases of syphilis by Wassermann's reaction from a special point of view—namely, the degree to which the sera of different cases react, and to indicate the probable advantages of this procedure in the practical application of the test. The cases examined from this special point of view are 41 in number and form part of a series of about 200 examined by a uniform routine method. Of these 200, about 120 had had, or were suffering from, syphilis, and about 100 gave a positive reaction.

Technique.

1. *Antigen or extract.*—1 gramme of guinea-pig's heart, washed free of blood and finely divided, was pounded up in 20 c.c. of alcohol. Fresh extract was made at least once a week, always in the same way, and kept in the dark at 0° C. This alcoholic extract was diluted for use in normal saline solution, 1 in 10. A watery extract of human syphilitic liver was also used in addition to the above for testing 11 cases, some syphilitic and some non-syphilitic, and both methods gave identical results.

2. *Complement.*—Guinea-pig's serum, not more than 24 hours old, diluted in normal saline solution, 1 in 10.

3. *Patient's serum.*—Heated at 56° C. for half an hour, and diluted in normal saline solution, 1 in 10.

4. *Sheep's blood corpuscles.*—The washed corpuscles were mixed with normal saline solution in 5 per cent. suspension.

5. *Rabbit's serum hæmolytic for sheep's corpuscles.*—The greatest dilution at which the serum caused complete hæmolysis with the amounts of complement and sheep's corpuscles used in all the tests was, in fresh samples, from 1 in 100 to 1 in 150. This point of highest dilution gradually diminished with keeping, and was ascertained from time to time. In carrying out the tests a dilution was always employed considerably lower than was requisite, generally 2- to 3-fold lower. The object of this procedure was to make sure of obtaining complete hæmolysis wherever fixation of complement had not taken place, the hæmolytic system being merely indicative and not concerned in the quantitative aspect of the test.

Routine test.—1-10th c.c. of each of the five factors enumerated was employed.

For each serum to be tested there were two tubes, one with complement and serum alone, the other with complement and serum plus extract, the former serving as a control. One tube containing complement and extract alone served as a control for the whole series.

For the first part of the experiment (fixation of complement) 1½ hours at 37° C. was allowed. Hæmolytic serum and sheep's corpuscles together with ½ c.c. of normal saline solution were then added to each tube. The experiment was considered to be complete when all the controls showed complete hæmolysis—usually after the lapse of 25–30 minutes.

This routine method served as the basis for the further quantitative estimations. Of the sera which gave a definitely positive reaction as many as was convenient were selected and further examined by the quantitative tests in the following manner.

Method A.—Measurement of the degree of the positive reaction by finding the amount of complement absorbed.

Keeping the amounts of extract and serum 1-10th c.c., increasing doses of complement were used—2-10ths c.c., 3-10ths, and so on. A serum with which complete fixation still occurred with 3-10ths c.c. of complement, but partial or complete hæmolysis with 4-10ths c.c., absorbed three times its own bulk, or 3 "doses" of complement. It is in this sense that the word "dose" is used in Table I.

A method of testing with increasing doses of complement, differing in detail from the foregoing, was described by Dr. Ivy M'Kenzie in the *Journal of Pathology*.

Method B.—Measurement of the degree of positivity by finding the highest dilution of the serum at which it gave a positive reaction.

Keeping the amounts of extract and complement 1-10th c.c., 1-10th c.c. of the patient's serum was used, but its dilution, in place of the usual 1 in 10, was made progressively 1 in 15, 1 in 20, 1 in 30, and so on.

Elimination of two possible sources of error.—A certain amount of complement is absorbed by extract alone, or by serum alone, whether normal or syphilitic. To see to what extent such absorption occurred, tests were made on several occasions with different sera and different complements. The exact details of these minor tests need not be described, but it was found that of the extract 4-10ths c.c. or even 5-10ths did not completely absorb the 1-10th c.c. of complement, in the presence of which they had been kept at 37° C. for an hour or more; of serum, the amount that could be taken was almost always at least 5-10ths c.c. One may conclude that no great importance attaches to the amounts of complement absorbed by extract or serum, especially of the latter, in Method B, with increasing dilutions of serum.

A second point to be considered is whether the complement in the serum of different guinea-pigs varies markedly as to the amount of it required to effect hæmolysis with a standard hæmolytic system. On ten or more occasions the guinea-pig complement was tested in this respect, and it was found that complete hæmolysis occurred generally with 0·003 c.c. (3-100ths c.c. of the 1 in 10 dilution); occasionally 0·004 c.c. was needed.

With regard to any variation between different samples of complement as to the readiness with which they are absorbed by extract and serum separately, or by different combinations of sera and extract, the former point has already been considered, whilst, as regards the latter, it may be mentioned that the two quantitative methods already described were carried out with two sera, using the complement of two different guinea-pigs with identical results.

Results.

Method A.—Method of increasing doses of complement. The cases and the "doses" of complement absorbed are shown in Table I. 1+ signifies five doses at least.

TABLE I.

—	Absorbed 1 dose.	Absorbed 1½ doses.	Absorbed 2 doses.	Absorbed 3 doses.	Absorbed 4 doses.	Absorbed 5 doses.
6 cases of chancre or chancre and rash	1	3	2	—	—	—
6 cases of secondary syphilis ...	2	1	1	2	—	—
7 cases of tertiary syphilis ...	—	3	2	1	1	—
5 cases of congenital syphilis...	—	—	3	—	1	1+
2 cases of general paralysis ...	—	1	1	—	—	—

Of these cases, amongst congenital syphilis the most intense reaction was found.

The next place is occupied by severe tertiary lesions. The case which absorbed four doses was a woman, aged 24 years, who had numerous gummata about the face and neck, with deep ulceration and laryngitis, and presented a picture of very severe syphilis. The two cases of secondary syphilis that absorbed three doses were both suffering from eye affections, one from iritis (three years after infection), the other from interstitial keratitis. The majority of early cases do not absorb more than one and a half doses.

Method B.—Examination of the dilution up to which the serum gives a positive result. The cases examined by this method and the highest dilution at which they gave a positive reaction are shown in Table II.

TABLE II.

Dilution at which + ...	1 in 10.	1 in 15.	1 in 20.	1 in 30.	1 in 40.	1 in 60.	1 in 100 +
3 cases of chancre and rash	1	—	1	—	1	—	—
4 cases of secondary syphilis	2	1	—	1	—	—	—
8 cases of tertiary syphilis...	2	—	2	1	2	1	—
4 cases of congenital syphilis	—	1	1	1	—	—	1
1 case of general paralysis	—	—	—	1	—	—	—

The case with which a positive result was obtained in a dilution of 1 in 100 (at least) was a female aged six months; there were active signs of syphilis both in mother and child. The case that gave a positive result at 1 in 60 is the female, aged 24 years, with severe tertiary lesions above alluded to. The case of secondary syphilis giving the reaction when diluted 1 in 30 is an untreated case that had contracted the disease four months previously. One case included under secondary syphilis should readily be classed as cured or "latent," having received seven injections of mercury six months ago and showing no signs. This case was positive only in 1 in 10 dilution. One case only had the primary sore (of four weeks' duration); it was positive only at 1 in 10 dilution.

Table III. shows five cases tested by both methods, A and B.

TABLE III.

Nature of case.	Method A.	Method B.
Sore and rash	2 doses of complement absorbed.	+ with dilution 1–40
Mucous tubercles ...	1 dose ditto.	,, ,, 1–15
Tertiary syphilis ...	4 doses ditto.	,, ,, 1–60
Aneurysm	1½ ,, ditto.	,, ,, 1–30
General paralysis ...	2 ,, ditto.	,, ,, 1–30

This comparison of Methods A and B indicates that the latter is the more delicate test as to the degree to which the reaction is obtained with any serum. A minor advantage consists in the circumstance that it can be carried out with a much smaller amount of the patient's blood than can the former.

Advantages of the Quantitative Method of Increasing Dilutions.

1. It provides a means of stating the intensity of the reaction in simple terms, intelligible to one ignorant of the details of Wassermann's reaction—viz., serum positive in dilution of 1 in 20, 1 in 30, &c.; just as is done in other serum reactions, such as Widal's test.

2. The results given above, although not numerous, seem to warrant certain conclusions as to the degree to which a positive result is obtained with sera in different forms of the disease. The average case in the early stages is positive at about 1 in 15. Some of the cases many years after infection still retain a trace of the taint without having marked signs; most of these give a positive reaction of slight degree. Congenital syphilis as a rule gives an intense reaction. Similarly, as regards the amount of complement absorbed in the method of increasing doses, the degree attained seemed in a good number of cases to be proportional to the severity of the disease. Now a positive Wassermann reaction obtained in a patient suffering from an obscure disease may or may not explain the nature of that malady. Syphilis in the past history of such a patient may be a mere coincidence, sometimes a misleading coincidence. This might be the case if the positive result were given only in low dilution, but with a positive result at 1 in 30 or 1 in 40 it would be much more probable that the disease in question was syphilitic.

3. The quantitative method would probably give more assistance than the ordinary routine test in judging of the improvement and prognosis in a case under treatment. For example, a severe case, having given a positive reaction at the beginning of treatment, may still give a positive reaction at a later stage, although improvement is occurring; whereas, if the degree of positive reaction be measured, the serum may be found at successive examinations to be giving the reaction in lower and lower dilutions. The writer has not had the opportunity of testing the serum of *the same patient* at successive stages of improvement; but positive reactions, occurring only in low dilutions of the serum, were obtained in several cases treated for varying periods—some of them improved or almost cured; and these patients had suffered from marked syphilitic lesions, gummata, for example, which, when still active and progressing, generally are associated with a positive reaction of marked degree.

The suggestion is offered that the Wassermann reaction should be made a uniform standard test, with amounts based, for choice, on the decimal system, and that, taking 1 in 10 as the lowest dilution for the serum to be tested, the degree of positive reaction be stated in terms of the highest dilution at which a positive result occurs—1 in 20, 1 in 30, and so on, or more simply, 1, 2, 3, &c., degrees or units of positive reaction.

It should be added that the technique of the routine method described in the beginning of this paper is practically that of Wassermann's original method, and is that adopted in the Pathological Department of St. Bartholomew's Hospital by Dr. M. H. Gordon, to whom the writer's thanks are due for advice and encouragement.

PRELIMINARY NOTE ON

THE COMPARATIVE VALUE OF THE VARIOUS METHODS OF ANTI-SYPHILITIC TREATMENT

AS ESTIMATED BY THE WASSERMANN REACTION AND CLINICAL OBSERVATION.

BY CHARLES GIBBS, F.R.C.S. ENG.,
SURGEON TO THE LONDON LOCK HOSPITALS, AND SURGEON TO CHARING CROSS HOSPITAL;
AND
H. WANSEY BAYLY, M.R.C.S. ENG., L.R.C.P. LOND.,
PATHOLOGIST TO THE LONDON LOCK HOSPITALS.

THE technique of the Wassermann reaction as first described being a somewhat lengthy and complicated one, it has naturally followed that a very large number of "simplified" methods have been brought forward by numerous observers. Fleming has suggested a modification of Hecht's and Bauer's techniques, which he claims gives equally good results to the original, and which is simple and easy to work; but other observers, including ourselves, have not succeeded in obtaining as satisfactory results with his technique as with the original as modified by one of us, and the general consensus of opinion is in favour of the original compared with any simplified one. Noguchi, and later von Dungern, advocate the use of complement and hæmolytic antibody dried on filter paper, but the question as to the rate of loss or alteration of complemental content has not yet been sufficiently worked out to enable us to use this method with confidence that the results will be reliable.

The clinical value of Wassermann's test is twofold: (1) it assists us to arrive at a diagnosis; and (2) it gives us a rough indication of the progress made under treatment.

Syphilis, like all other diseases, varies in its virulence and the length of time required for its cure according to the individual attacked. Some individuals recover without any treatment at all; in others a short course of mercury is probably sufficient. The majority, however, require a treatment extending over two or three years, and some require a long treatment of five or ten years, and some are never cured.

Without the Wassermann reaction we have no means of judging, in the great majority of cases, as to when cure has taken place. Symptoms have disappeared within a month or two after commencing treatment, after which we have nothing but rule-of-thumb to guide us. In the state of our present knowledge, however, we do not think that it would be justifiable to recommend less than three years' treatment, even if a succession of negative reactions have been obtained, for we know that if treatment is left off too soon a positive reaction will return.

The history of the Wassermann reaction is too recent for us yet to have acquired sufficient data in regard to its value as a guide to permanent and complete cure. Even in a case where a succession of negative results has been obtained after all treatment has been left off, we cannot until another 20 years have passed be certain that the disease is finally and absolutely obliterated and that no late manifestation will ever occur. By its means we have indeed learnt that many cases considered cured were not cured and it is the general opinion that three negative reactions taken at three or six months' intervals, during which no mercury is given can be considered as an absolute cure. We can only say that an opinion based on this evidence is of far greater value than an opinion based only on clinical or rule-of-thumb ground, but we cannot yet be certain that such an opinion would invariably be correct. Too much reliance should not be placed on a solitary negative reaction for the exclusion of syphilitic infection.

We have endeavoured to find out by means of the Wassermann reaction the comparative value of various antisyphilitic drugs and the method of their administration, and although our series is short and incomplete we think that perhaps this preliminary note of the results obtained in 231 cases may be of interest. Our work on this subject has only extended over a few months, and the results obtained must necessarily be inconclusive.

Pill treatment.—Of 138 cases treated with pills 66 had received under six months' treatment, and of these 62 gave a positive reaction (94 per cent.). The proportion of negative reactions, therefore, was not higher than would be expected in untreated cases. We therefore conclude that under six months pill treatment has no effect on the Wassermann reaction. After this period, however, the effect of mercury is clearly shown. Of 33 cases that had received from six months to a year's treatment 19 were positive (57 per cent.) and 14 negative. Of 25 cases that had received 18 months' treatment 10 were positive (40 per cent.) and 15 negative.

Injections.—Of 25 cases treated with calomel injections which had received 12 injections at weekly intervals 22 were positive (88 per cent.) and 3 negative.

Inunction.—Of 16 cases of inunction treatment all were positive.

Suppositories.—Of 15 cases treated with mercurial suppositories all were positive.

Potassium iodide.—Of 20 cases treated for a month with large doses of potassium iodide all were positive.

Arylarsonates.—Of 15 cases treated with one course of 10 injections of 10 grains of arylarsonates only one gave a negative result at the conclusion of the treatment. Colonel F. J. Lambkin, R.A.M.C., however, states that a negative reaction is obtained after several courses of treatment with the arylarsonates extending over the period of a year.

The above results were obtained when only one strength of complement (1 in 10) was used. For the last three months, however, we have followed Captain Harrison's method of using two amounts of complement, 1 in 10 and 1 in 5, and so have been able to arrive at a roughly quantitative estimation of the complement-fixing power of the serum. We have examined 93 sera in this way with the following results.

Pill treatment.—Of 32 cases that had received under six months' pill treatment 30 were positive with both doses of complement (94 per cent.) and 2 were positive with the smaller dose, but showed some hæmolysis with the larger dose (6 per cent.). Of 11 cases that had received treatment of from six months to one year 3 were positive with both amounts of complement, 6 were positive with the smaller amount, but showed some hæmolysis with the larger amount, and 2 showed hæmolysis with both amounts of complement—i.e., 70 per cent. showed the effect of mercurial treatment. Of 7 cases that had received 18 months' treatment, 1 was positive with both amounts of complement, 4 were positive with the smaller, but showed some hæmolysis with the larger amount, and 2 showed hæmolysis with both amounts of complement—i.e., 86 per cent. showed the effect of treatment. In other words, of the 17 cases which had received over six months' treatment only 3 showed hæmolysis with the smaller amount of complement, whereas 14 showed hæmolysis with the larger amount of complement—i.e., 83 per cent. showed influence of treatment. All those showing a positive result with the smaller amount of complement are active syphilitics, but the fact that so many of these showed some hæmolysis with the larger dose of complement indicates in our opinion that they were getting under the influence of the drug, for without treatment the larger amount of complement is nearly always fixed. The fact that 94 per cent. of those which had received under six months' treatment were equally positive with both amounts of complement confirms our original finding that under six months pill treatment has practically no effect on the Wassermann reaction.

Inunction.—Of 11 cases of treatment by mercurial inunction, all under three months' treatment, 2 were positive with both amounts of complement, and 9 were positive with the smaller amount, but showed some hæmolysis with the larger amount—i.e., 82 per cent. showed effect of treatment, therefore, and this after only three months.

Injections.—Of 17 cases that had received 12 injections of calomel 11 were positive with both amounts of complement, and 6 were positive with the smaller, but showed some hæmolysis with the larger amount; 35 per cent. therefore showed effect of treatment.

Suppositories.—Of 14 cases treated with suppositories for under six months, only 3 (21 per cent.) showed any effect of treatment.

These figures are, of course, too small to prove anything, but it is suggestive that 82 per cent. of inunction cases show effect of treatment in three months, whereas only 6 per cent. of pill cases show any effect of treatment in six months, and the conclusion would seem to be that inunction is the most rapid method of getting the patient under mercury, that calomel injections are second, and that pills and suppositories are a long way behind.

We are entirely satisfied as to the great value of the Wassermann reaction from the diagnostic point of view, such clinically doubtful cases that gave a positive reaction always showing later either by their reaction to mercurial treatment or by the development of clinical symptoms that they were syphilitic. In so far as we have gone at present in regard to treatment also the pathological evidence as estimated by the Wassermann reaction and the clinical evidences seem, in the great majority of cases, to go hand in hand.

We wish to express our indebtedness to Dr. Charles Slater, director of the Clinical Laboratories at St. George's Hospital, where the pathological work connected with this paper was carried out.

PUBLIC HEALTH AND THE NORFOLK SCHOOLS.

Mr. F. H. Millington, chairman of the Education Committee of the Norfolk County Council, attended a meeting of the Norfolk County Association of the National Union of Teachers held at Norwich on April 16th, and gave an address on Public Health Administration and Education. Mr. Millington said he thought the most important work that county, town, and district councils had to do at the present time was to complete if possible the organisation of public health administration. Most of what he had to say related to medical inspection. Over a thousand men were now engaged in the school medical service, many hundreds of them being full-time appointments, as well as several hundred nurses and women health visitors. In the county of Norfolk more than two-fifths of the school children had been medically inspected. The results of these inspections might be roughly summarised as follows: 25 per cent. of the children may be said to be all right, 75 per cent. had something requiring medical attention, 17 per cent. of these needing treatment as early as possible. The defects discovered justified the institution of medical inspection. Each child was to be examined three times during its school career—at its entrance, half-way through the course, and on leaving. The parents were notified if anything serious was found, and special cases were examined oftener if required. The principle underlying the whole scheme was the recognition that, after all, one of the best endowments a working man or woman can have is sound health, and that the foundations for this must be laid in childhood. It could not be yet stated what the cost of medical inspection per head in Norfolk was, but taking the whole country it had been estimated approximately as 4¾*d.* per child and in urban districts up to 7½*d.* per annum. The teachers had willingly and cheerfully given their help and no difficulties had been raised by the parents. In Norwich as many as 67 per cent. of the mothers had attended the inspections. With the sanction of the Local Government Board local education authorities may and ought to arrange for medical treatment. The Norfolk county council had agreed to allow a sum of £200 to be spent during the current year for this purpose. About 25 per cent. of the parents had voluntarily done what was medically advised. Dr. J. T. C. Nash, medical officer of health of Norfolk county, in the course of an address which followed, stated that the coöperation of the teachers had been beyond praise and had been testified to by the medical officers. Parents were welcomed at the medical inspection of their children because it was desired to stimulate a sense of duty in mothers with respect to the health of their children. Dr. Nash went on to speak of the importance of "tooth-brush drill," and urged that children should be taught to use the tooth-brush at least three times a day. Mr. Arnett, President of the Norfolk County Association of Teachers, said he believed one result of medical inspection would be that the curriculum of the schools would be lessened and more time would be devoted to cultivating the health of the children.

PROGRESSIVE DESTRUCTION OF THE TEETH SOCKETS: CHRONIC GENERAL PERIODONTITIS.

(PYORRHŒA ALVEOLARIS, ALVEOLAR OSTEITIS, INTERSTITIAL GINGIVITIS.)[1]

BY J. F. COLYER, M.R.C.S. ENG., L.R.C.P. LOND., L.D.S. R.C.S. ENG.,
DENTAL SURGEON TO CHARING CROSS HOSPITAL AND ROYAL DENTAL HOSPITAL, ETC.

IN the following remarks on periodontal disease it is intended to draw attention to the following points: (1) the morbid anatomy of the disease; (2) the clinical appearances and symptoms; and (3) the relation of the clinical appearances to the destruction of the bone.

Morbid Anatomy.

If specimens of human maxillæ which show this disease be examined the first change noticed will be the disappearance of the bone between the teeth, leading to the formation of spaces (Fig. 1).

The next stage is marked by further destruction of the bone, the whole tooth socket being gradually involved. The bone immediately bordering the tooth disappears first, and so produces cup-like spaces around the teeth. The condition of the bone to the naked eye then presents the appearance of osteoporosis or rarefying osteitis (Fig. 2).

In specimens showing more advanced stages the bone forming the tooth sockets will be found almost destroyed, affording but slight hold for the tooth.

In the maxilla, especially in the region of the molars, the bone is more involved in the disease than is the case in the mandible. This is to be accounted for by the different nature of the osseous tissues in these two bones. Irregular patches of calculus will often be seen on the teeth near the necks, and at times the surfaces of the roots will be found completely covered with an irregular dark-brown deposit. In some specimens the extent of the changes around the teeth appears to be slight, the margin of the alveolar process having receded, but the bone itself presenting a sclerosed rather than an osteoporotic condition. In these specimens, too, a considerable thickening of the outer alveolar plate will at times be noticed (Fig. 3).

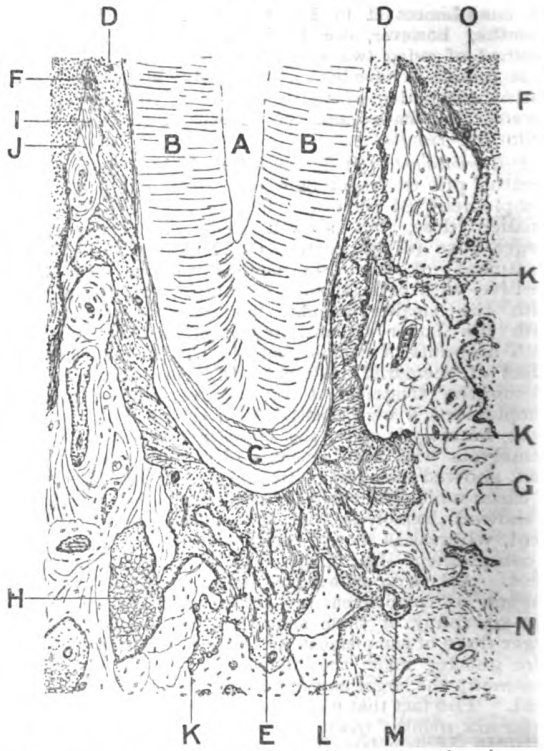
In animals that have been the subjects of this disease exactly similar changes are to be found in the bones, but the teeth show greater deposits of calculus owing to the absence of the system of artificial cleaning adopted by human beings, and recent specimens will often show the spaces between the teeth choked up with food débris. The following specimens show the different stages of the disease in animals.

Fig. 4 shows the skull of a Chinese palm-civet (*paradoxurus larvatus*), and shows the cupping of the sockets the result of rarefying osteitis.

The next specimen (Fig. 5) is one from a Panolia deer (*cervus eldii*); the condition is chronic and the destruction is most marked in the region of the molars where the force of mastication is greatest.

The next specimen (Fig. 6) is that of an ordinary domestic dog, and is a fair example of the deplorable state of the mouths of many of these animals.

Fig. 7 is a specimen from a spotted hyæna (*hyæna crocuta*), and shows very clearly the marked destruction of the alveolar process from rarefying osteitis. This is the stage where the teeth are almost on the point of dropping out.



The next specimen (Fig. 8) shows an advanced stage of the disease in a Vervet monkey (*cercopithecus lalandii*).

Microscopical investigation of the tissue in the various stages of this disease has not been carried out to any considerable extent. A useful paper was published by Znamensky. This author records the result of his examination of sections obtained from a female, aged 39 years, who had suffered from pyorrhœa alveolaris. The patient died of acute anæmia, the result of hæmorrhage after parturition. The decalcification of the preparations was accomplished by means of a 3–5 per cent. solution of trichloracetic acid. Some of the sections were stained with eosine and hæmotoxylin, and others in Löffler's blue, and the sections were afterwards mounted in Canada balsam.

The series obtained showed the progressive development of the pathological process in this case. In all the sections a deposit of calculus was present under the gum margin. The sections showed that the pathological process was of an inflammatory character, originating in the gum, and then successively involving and leading to the destruction of the periodontal membrane and the adjacent bone. The destructive process in the bone near the margin of the socket consisted in decalcification of tissue and transformation first into an osteoid tissue and afterwards into a fibrous intervening tissue with the subsequent infiltration of the latter with leucocytes. In the part of the socket where the bone marrow was present lacunar absorption of the bone was seen. The whole process was of the type of a rarefying inflammation.

Dr. E. S. Talbot has examined the patho-histology of the disease in a series of dogs, and has shown that the earliest manifestation is in the gingival margin, and that with the progress of the disease both the periodontal membrane and the bone become involved. The absorption of the bone is at times quite rapid, and takes place by (*a*) lacunar absorption, (*b*) the formation of perforating canals, and (*c*) halisteresis (disappearance after prior absorption of lime salts). The main features of the condition of the bone are well shown in Fig. 9, a section taken from the human subject.

FIG. 9.

A, Pulp cavity. B, Dentine of tooth. C, Hyperplasic cementum around apex of root. D, Peridontal membrane, greatly thickened—hyperplasic. E, Indifferent tissue at apical region greatly increased in amount. F, Free edge of bone of socket becoming converted into fibrous intervening tissue. G, Bone of socket presenting earliest signs of osteoporosis. H, Large osteoporotic space in bone of jaw filled with bone marrow. I, Bone of socket partially decalcified and converted into osteoid tissue. J, Junction of living with decalcified bone. K, Osteoclasts producing lacunar absorption. L, Bone of jaw only slightly altered by disease. M, Sequestrum undergoing peripheral absorption. N, Soft cancellous tissue slightly changed from normal. O, Inflammation of gum at neck of tooth. (From a drawing by Mr. A. Hopewell-Smith.)

Clinical Appearances.

In a young adult, where the mouth is in a normal condition, the gums will he noticed to fit closely around the necks of the teeth, the spaces between the teeth being filled with tags of gum. In the earliest stage of the disease there is a slight congestion of these tags of gum, and by passing a probe into the interproximal spaces it can be shown that the gum has undergone a certain amount of destruction. The whole of the margins of the gums gradually becomes congested and bleeds readily. The tags of gum between the teeth then gradually disappear and the normal festoons become obliterated. An examination of the teeth at this stage will usually disclose in the approximal spaces food and other débris, while small nodules of calculus are generally present on the teeth. If the gums are compressed a small quantity of discharge may be seen escaping by the side of the teeth. Finally, the bone becomes involved in the inflammatory process, and, with the peri-odontal membrane, is gradually destroyed, and the muco-periosteum gradually recedes. The recession of the gums does not usually proceed as quickly as the destruction of the alveolar process, with the result that around the teeth deep pockets are formed, and in these pockets pus and other morbid material accumulate and so aggravate the condition.

At this stage the mucous membrane will appear deeply congested, the gums are swollen at their free margins and bleed readily at the slightest touch. The roots of the teeth are more or less exposed, and covered with a layer of hard greenish-brown calculus; there is a fœtid discharge, and the breath has a repulsive odour due to indol-forming organisms. A sickly sour odour of the breath is noticeable when yeasts and bacteria causing carbohydrate fermentation are present. The teeth are freely moveable, and may become so loose that they can be removed quite easily. If the disease is left untreated the teeth are lost one by one, and with the loss of the teeth the inflammatory process invariably clears up.

In advanced cases superficial glossitis is often present, and the tonsils and pharyngeal mucous membrane are also inflamed. An unpleasant taste is experienced in the morning. There is constant hæmorrhage from the gums which is swallowed during the day, but at night it occasionally escapes from the mouth and stains the pillow. This latter symptom is worthy of special attention, as it may be mistaken for hæmorrhage from the lungs.

The clinical appearances of the disease, which vary considerably, are determined by the general condition of the patient, the resistance of the tissues, and the hygiene of the mouth. At one period the condition may be acute, with a free flow of pus from the tooth sockets and a rapid destruction of the tissue. This state of evanescence is perhaps followed by a period during which the inflammation may be only slightly marked.

In some cases the teeth are comparatively free from calcareous deposits; in other cases they are completely coated. The disease, too, may be more active around the anterior than the posterior teeth, or *vice versâ*. Again, the destruction of tissue may be more active in one region of the mouth than another. This is exemplified in the case of the incisors and canines, the destructive process being often more advanced on the palatal than on the labial aspect. In severe cases the disease may spread in the maxilla to the antrum, or in the mandible to the body of the bone.

In some cases where the hygiene of the mouth is carefully looked after the gums appear fairly normal in colour, and abnormal looseness of the teeth is the only indication of the presence of the disease. In these cases the probe discloses deep pockets, and on pressing the gum a discharge can be expressed from the tooth sockets. In a few cases the disease is slow in its progress, and the surrounding bone actively reacts to the injuries caused by the toxic products in the pockets; this is well seen in the case shown in Fig. 3.

In certain cases there seems to be a tendency to the formation of granulation tissue, causing the condition to simulate sarcoma. In one case under observation associated with myxœdema, the gums were friable and presented a translucent appearance.

The disease may often be well advanced without the patient being conscious that anything is wrong, the only symptom being a tendency for the gums to bleed readily, and this is often unheeded by the patient. With the formation of spaces between the posterior teeth, neuralgia, arising from irritation of the exposed cemental tissue, may be present. In the later stages there is often persistent neuralgia owing to the main trunks of the nerves being involved in the diseased process. Where pus formation is active the patient will often complain of a general itching of the gums.

Whether the disease can be transmitted from one individual to another is an open question, but the balance of evidence is rather against it.

In patients of a gouty diathesis, the clinical appearances present certain features which are typical, and in the opinion of some the periodontitis is considered to be closely associated with the uric-acid diathesis. According to these authors, gouty periodontitis seldom manifests itself before the age of 30, and in most cases the patient has reached the age of 45 to 50. There is usually a well-marked history of gout. In the earliest stages there is a gingivitis, the teeth are often free from caries and show signs of well-marked attrition. Subsequently the periodontal membrane becomes involved, causing recession of the gums and absorption of the alveolar process. The mouth may remain in this condition for years.

The margin of the gums often presents a thickened appearance, which is probably due to a productive inflammation of the muco-periosteum. An examination of the sockets with a probe will not disclose any deep pockets or much calculus. At intervals synchronous with a lowering of the standard of general health, the gums will appear congested, a catarrhal-like discharge or even pus may exude from the pockets, and the teeth will become sensitive to pressure, the inflammatory process appearing to involve the whole periodontal membrane; the teeth will be hypersensitive to thermal changes, and the patient will often complain of shooting pains in the region of the alveolar process. The oral condition improves with that of the general health, but the roots of the teeth will be left a little more exposed. The attacks tend to become more frequent as age advances, and one or two teeth during each attack appear to be singled out, as it were, for an extra dose of the specific poison. The inflammation in the tooth or teeth may stop short of suppuration, but even when a general improvement has taken place a distinct looseness of the tooth or teeth persists. During a subsequent attack the tooth becomes extremely loose, and the gum overlying the upper half of the root may become swollen and a fluctuating swelling appear. An incision into the swelling will disclose a glairy, mucus-like fluid, or even pus.

If the swelling is not incised it may break externally, or the fluid may wend its way towards the gingival margin and so discharge at the neck of the tooth. An examination of the tooth will disclose a living pulp. In such teeth a rapid destruction of the periodontal membrane and alveolar process takes place and the teeth become quite loose and are lost. With the advance of years the attacks occur with increasing severity, the teeth becoming loose partly by the destruction of the membrane commencing at the gingival margin and partly by acute exacerbations in one or two teeth as mentioned above.

Radiographs in Relation to Clinical Appearances.

Clinical appearances alone are not altogether satisfactory guides as to the extent of the disease, and it is only by the aid of radiography that the extent of the bone destruction can be estimated with any degree of accuracy. The following cases will serve to demonstrate the amount of bone destruction in relation to the clinical appearances.

In Fig. 10 is seen the mandibular incisor region of a girl aged 15 years. The gums were normal in appearance, with the exception of the gingival margins around the medial incisors and the left lateral and canine, where the gums were inflamed and the interdental papillæ slightly thickened. Examination with a probe at these points showed the presence of slight "pockets." The radiographs (Fig. 11) show the alveolar process to be normal with the exception of the lower incisor region, where the septa between the teeth have been partially destroyed.

The case shown in Fig. 12 depicts an early stage of the disease. Clinically there was no recession of the gums beyond a partial disappearance of the interdental papillæ between the lower incisors. There was a marked marginal gingivitis together with a congestion of the whole of the gums. There was a free discharge from the pockets around the teeth. This patient had a well-developed arch and there was marked attrition.

The radiographs (Fig. 13) show that the alveolar process

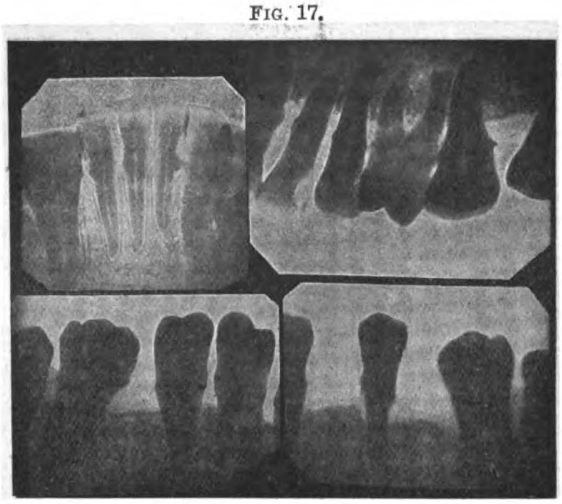

FIG. 18.

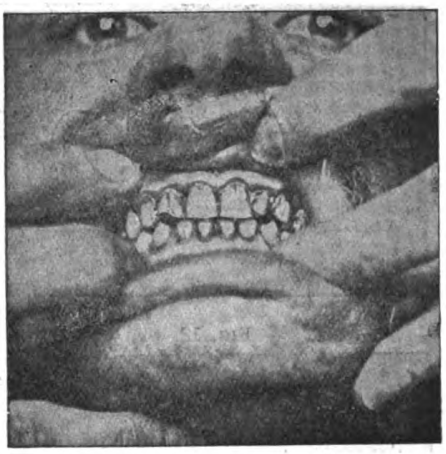

FIG. 19

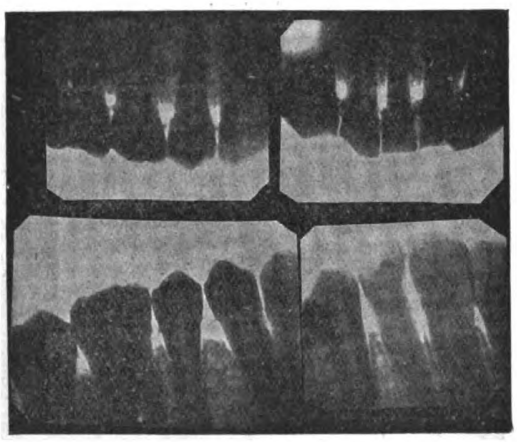

FIG. 20.

FIG. 21.

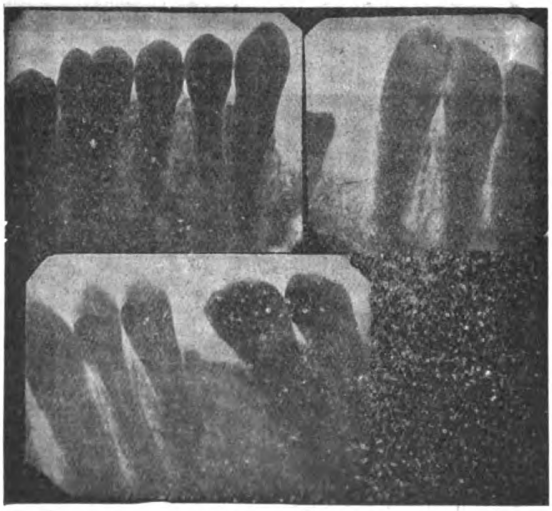

FIG. 22.

already involved and that the destruction of bone has advanced to a considerable extent in the lower incisor region.

In the next patient (Fig. 14) the clinical appearances suggest a more advanced condition of the disease than in the preceding case. The muco-periosteum was more swollen and congested. The interdental papillæ had quite disappeared but the gum margin on the labial aspects of the teeth just failed to cover the necks of the teeth. The radiographs (Fig. 15) show that the bone destruction is much more advanced than the gum recession.

FIG. 23.

The case shown in Fig. 16 illustrates an advanced case. The radiographs (Fig. 17) show the extensive destruction of the tooth sockets, also that the calculus only extends to just under cover of the gum margin.

The case shown in Fig. 18 illustrates some features which are of interest from the point of view of prognosis. The patient, a man aged 34 years, was a compositor by trade, and attended the out-patient department for dyspepsia. Beyond a well-defined marginal gingivitis the gums were normal in colour and firm in consistency. The teeth

FIG. 24.

were smothered with calculus, the gum margin was above the necks of the teeth, and the interdental papillæ had disappeared. Examination with a probe showed slight pockets around the teeth. The clinical features suggested that the disease was of slow progression and that there was comparatively little bone destruction. The radiographs (Fig. 19) show that the destruction is equal in all parts of the mouth, and that the inflammatory process extends only slightly beyond the margin of the bone.

In the case shown in Fig. 20 the patient was a mouth breather and complained of bleeding from the region of the mandibular incisors. The teeth had been regularly cleaned. The gums were well up to the level of the necks of the teeth and the interdental papillæ were not destroyed. There was no gingivitis except around the mandibular incisors, where pus was present. An examination with a probe showed that there was extensive destruction of the alveolar process in the region of the mandibular incisors, while in the rest of the mouth the bone was unaffected. The radiographs shown in Figs. 21 and 22 demonstrate clearly that the only region showing bone destruction is that of the mandibular incisors (radiograph Fig. 22, A).

The radiographs shown in Fig. 23 show an advanced stage of bone destruction and also serve to demonstrate the liability of the antra to become infected in these cases. Note the relation of the antra to the molar teeth.

The radiograph shown in Fig. 24 is from the incisor region. Suppuration was present in the bone over the central and lateral incisors, but the pulps of these teeth were alive, although they showed signs of commencing pulpitis. The path of infection from the gingival margin by the side of the lateral incisor is clearly shown in the radiograph.

THE BACILLUS INFLUENZÆ AND SYMBIOSIS.

BY R. W. ALLEN, M.D., B.S. LOND.,

LATE CLINICAL PATHOLOGIST, MOUNT VERNON HOSPITAL FOR CONSUMPTION; LATE PATHOLOGIST TO THE ROYAL EYE HOSPITAL AND LATE GULL RESEARCH STUDENT IN PATHOLOGY, GUY'S HOSPITAL.

DURING the past year it has been my good fortune to extend considerably my acquaintance with the bacillus influenzæ. As I have already pointed out in THE LANCET,[1] the great majority of cases of so-called "influenza" are not really such, but are instances of infection by the pneumococcus. In a small percentage the bacillus influenzæ and pneumococcus are joint invaders, and in about an equal number of cases the bacillus influenzæ alone appears to be responsible for the symptoms. At that time I had never met with an instance of true chronic influenza, but since then I have encountered 11. Two of the sufferers came from Ireland, 3 from Manchester, 1 from Scotland, and 5 from London, and upon these I have been able to make the following interesting observations.

In the first place, so long as the infection remains in a truly chronic condition no dissemination by means of contact appears to occur, but so soon as climatic conditions determine the lighting-up of an acute attack the carrier becomes a source of infection to all around him. Some of these cases date back the inception of their chronic catarrh 10 to 15 years, and I have little doubt that the recurrence from time to time of influenza among the community is due entirely to a lighting-up of acute attacks in these chronic carriers. Secondly, in about 50 per cent. of these cases I used to find it impossible to cultivate the bacillus influenzæ from the secretion, although present therein in enormous numbers; the purer the infection the more difficult was it to obtain a living culture upon the surface of a blood agar plate. If, however, but four or five colonies of pneumococcus or staphylococcus albus developed upon incubating the plate culture, it was noticed that around these the bacillus influenzæ grew with the utmost freedom; attempts at subculturing the latter were as a rule futile. It thus appeared that in many instances symbiosis with the pneumococcus or staphylococcus albus was essential to the multiplication of the bacillus influenzæ. It occurred to me to endeavour to learn the nature of this symbiosis, and to ascertain whether it was the converse of what occurs when one endeavours to cultivate the bacillus of Friedländer and staphylococcus albus side by side.[2]

Accordingly, from a case of chronic influenza where the staphylococcus albus and bacillus influenzæ occurred together a series of stroke cultures were made from the secretion upon a blood agar plate and the staphylococcus isolated; 20 or 30 of this micro-organism were then introduced into 15 cubic centimetres of melted blood agar at 45° C., and a plate prepared; upon the solidified surface of this a series of stroke cultures were made from the secretion

[1] THE LANCET, Feb. 13th, 1909, p. 500.
[2] Vide THE LANCET, Nov. 28th and Dec. 5th, 1908.

as before. After 24 hours' incubation it was observed that wherever there was a deep colony of staphylococcus, upon the surface of the agar above it the bacillus influenzæ was flourishing greatly, and there alone. Now, this was obviously not true symbiosis, for there was a layer of blood agar perhaps an eighth of an inch thick between the deep colony and the superficial growth, and the deduction was made that the staphylococci so modified the medium in their growth by the formation of soluble toxin or otherwise as to favour the development of the bacillus influenzæ. The following experiment shed further light upon the nature of the process. Some staphylococci were incubated in broth for 24 hours and then killed by heating to 63° C. for 45 minutes; 2 cubic centimetres of this sterilised culture were then introduced into 10 cubic centimetres of blood agar and a plate prepared. Some bacilli influenzæ which refused to grow upon blood agar without the addition of this broth culture were used to inseminate the surface of the plate. After only eight hours' incubation there appeared the most vigorous growth of the influenza bacillus which I had ever seen. It would thus appear that the staphylococcus albus does form a soluble toxin, and that this toxin is highly adjuvant to the multiplication of the influenza bacillus. Identical experiments were made with the following: pneumococcus, staphylococcus aureus, bacillus coli, bacillus acidi lactici (Hüppe), and micrococcus paratetragenus, and a similar effect was observed in varying degrees.

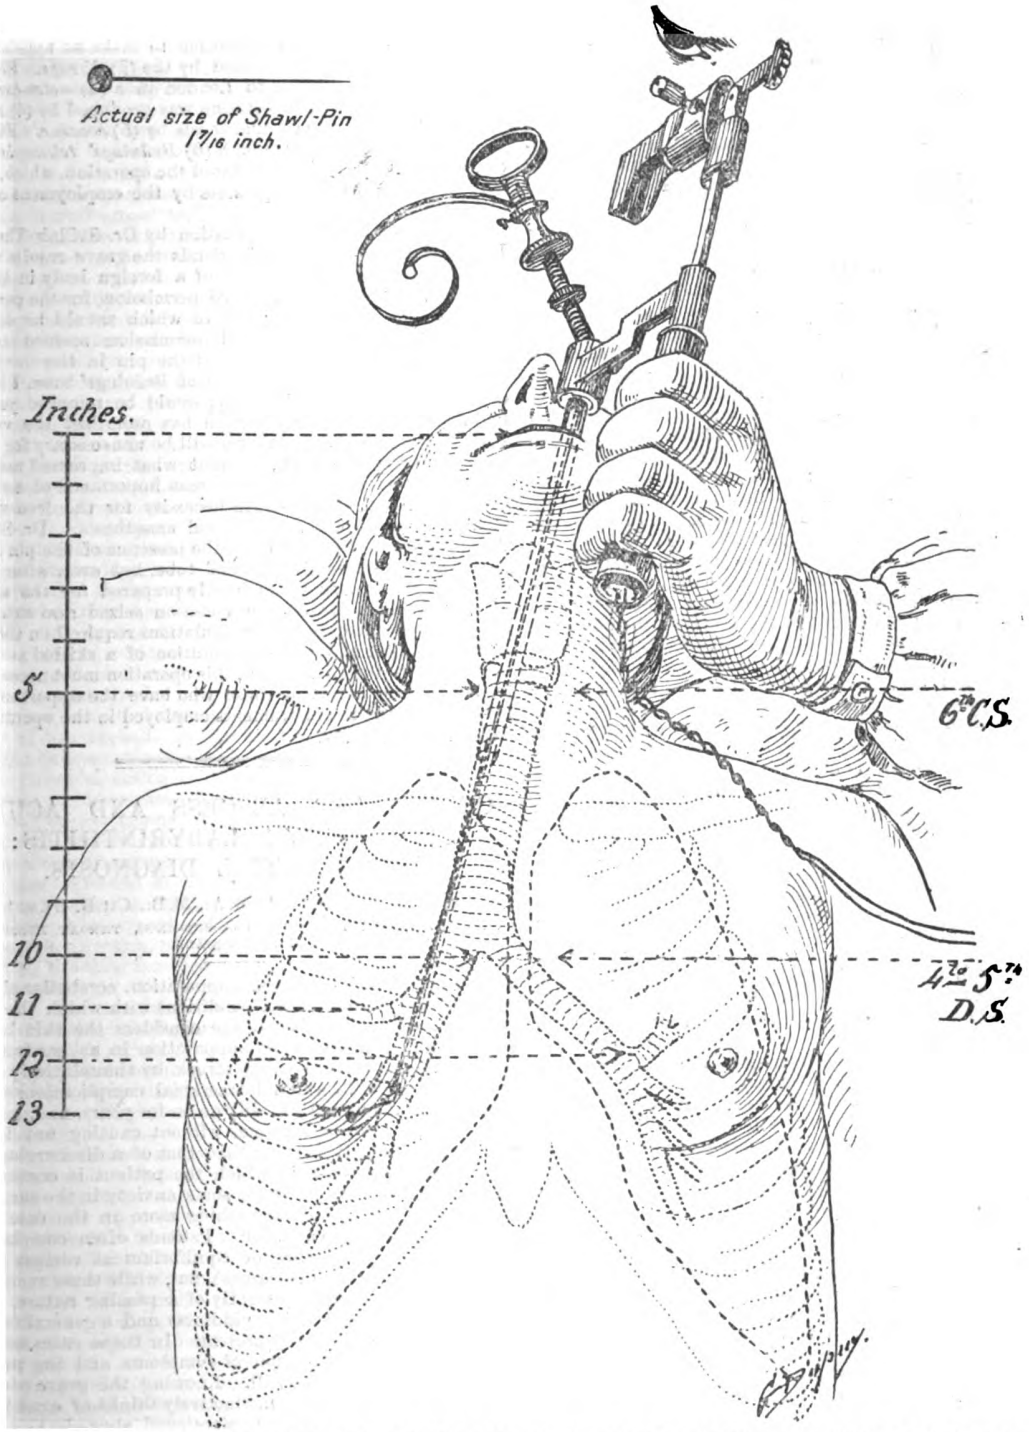
These observations seem to me to shed considerable light upon the nature of symbiosis and to raise several questions of very great practical importance. For instance: 1. Does the same thing hold for growth in the human subject? Is it necessary for the way to infection by the bacillus influenzæ to be paved by weakening of the tissues by the toxins of other microbic invaders? 2. Does the same hold good in other pathological conditions—for instance, in pyorrhœa alveolaris and in pulmonary tuberculosis? This question I am now engaged in investigating. 3. If so, does this shed any light upon the methods of treatment that should be adopted? Immunity against the influenza bacillus is very difficult to establish, and I have conclusively proved to myself that doses of 500 and even 1000 millions of a vaccine are necessary before a chronic influenza infection begins to benefit. In such cases would the better procedure be to attack the symbiotic bacteria and exterminate them? I am satisfied in my own mind that the good results reported as achieved in some cases of pyorrhœa alveolaris have been brought about in this way, and I cannot help feeling that a thorough investigation of the relationship one to another of the tubercle bacillus and the secondarily infecting organisms in pulmonary tuberculosis will point the way to more satisfactory methods of treatment.

Harley-street, W.

THE NATIONAL ASSOCIATION FOR THE ESTABLISHMENT AND MAINTENANCE OF SANATORIA FOR WORKERS SUFFERING FROM TUBERCULOSIS.—The annual report of this association, which was presented at the annual meeting held at the offices in Gray's Inn-road, London, W.C., on April 20th, shows a record of progress which speaks well for the business capacity and attention to details of the management committee of the Benenden Sanatorium. During the year 1909 an addition has been made to the administration block for the accommodation of the staff, and the work in connexion with the erection of the Countess Cadogan Pavilion has been greatly accelerated. It is hoped that it will be ready for use in the early part of next year. 63 beds are maintained in the sanatorium by various societies, 35 being devoted to the Post Office Association. The Hospital Saturday Fund maintains 15, and the Hearts of Oak Benefit Society 5. The medical report states that during 1909 229 patients left the sanatorium, and of these 3 were probably non-tuberculous. Of the remainder 94 were discharged with the disease arrested, 99 were improved, 32 were unimproved, and 1 died An attempt is made to keep in touch with as many patients as possible after leaving the sanatorium, and of 98 patients who left more than six months ago and less than 12 months ago 83 have been traced. Of these 38 are in full work, 4 in partial work, 21 doing no work, 13 have died, and 7 have been readmitted. It should be mentioned that some of those who are doing no work are in good health, but are out of employment for other reasons.

REMOVAL THROUGH THE MOUTH OF A SHAWL-PIN IMPACTED IN A SECONDARY BRONCHUS.

BY STCLAIR THOMSON, M.D., F.R.C.P. LOND., F.R.C.S. ENG.,
PHYSICIAN FOR DISEASES OF THE THROAT, KING'S COLLEGE HOSPITAL.



With Remarks by F. DE HAVILLAND HALL, M.D. Lond., F.R.C.P. Lond.

ONE hundred and five deaths from foreign bodies in the air and food passages, or from ill-advised efforts at removal, were recorded in North America in five years. In a large percentage of cases blind groping after foreign bodies aggravates the mischief and fails to remove the intruder. Chevalier Jackson points out that the above figures show the necessity of acquainting the general profession with the advances already made, and still being made, in œsophagoscopy and bronchoscopy.[1]

Although laryngologists in this country are now generally acquainted with Killian's method of direct endoscopy, yet the records of successful cases are not so numerous as in foreign literature, and the following story illustrates the rapid, certain, and safe relief of a condition which a few years ago would have seemed hopeless, "considering the serious and almost invariably fatal consequences of a foreign body firmly impacted in a bronchus."[2]

On a Friday afternoon a young married lady was holding a shawl-pin between her teeth, when she laughed, and the pin vanished down her throat. So free was she from any spasm, cough, or discomfort in breathing that it was thought at first that the pin must have gone down the œsophagus. A careful search in this area by Dr. Arthur G. J. Thompson of Twickenham failed to detect it. The patient said that she felt no discomfort, but that with respiration she felt a flapping in her windpipe. Later in the evening she had a sensation as if the pin had moved over to the right side. On the next morning (Saturday) she felt that her movements in dressing caused the pin to move still further down into the right lung, and from that moment she ceased to have any pain. She was only conscious of a feeling of dull oppression and some discomfort in moving the right arm. On the same morning, after examination by the X rays, Dr. Thompson telephoned for Mr. Albert Carless, who kindly referred the case to me. The patient came to London in a motor-car that afternoon, and an X ray examination by Mr. A. D. Reid distinctly showed the pin lying about one and a half inches below and slightly internal to the right nipple, with the head downwards and moving freely upwards and outwards with each respiration. The same evening I had the advantage of a consultation with Dr. de Havilland Hall, and at 8 P.M. the patient was put under chloroform. No cocaine was used until the patient was anæsthetised, then I applied a 20 per cent. solution of cocaine successively to the pharynx, epiglottis, larynx, trachea, and the bifurcation of the trachea. This was carried out under the bronchoscope, and it was interesting to note how extremely sensitive was the bifurcation of the trachea, although the patient was thoroughly relaxed. When all these reflexes had been abolished Brünings' telescopic tube was introduced and the right bronchus was searched. No trace of the pin could be found. Surprised at this, and thinking that the examination tube had overshot the foreign body, I retreated to the bifurcation of the trachea and once more carefully examined along the right bronchus, which is 3 inches long on the right side. Finding no trace of the pin, I turned to the orifices of the secondary bronchi. Contrary to what one had been taught of the anatomy of this region, the bronchus did not divide dichotomously into two fairly sized tubes, but appeared to break up at once into three small secondary bronchi. These were all seen to be quite empty. I thought that possibly during the four hours which had elapsed since the radioscopic examination in the afternoon the pin might have been coughed up and swallowed, or (as has happened) might have passed across to the left bronchus. I was about to suggest a further examination under the X rays when I thought

[1] American Medical Association, Transactions of the Section of Laryngology, June, 1909, p. 279.

Direct bronchoscopy. Removal of a shawl-pin impacted in a secondary bronchus (dorsal) of the right middle lobe. On the right-hand side of this semi-diagrammatic drawing there is indicated the correspondence of the cricoid cartilage to the sixth cervical spine, and of the bifurcation of the trachea to the interval between the fourth and fifth dorsal spinous processes. On the left-hand side of the drawing the distance is given, in inches, from the upper molar teeth to the cricoid cartilage, the bifurcation of the trachea, the branch of the right bronchus to the upper lobe (eparterial branch), the first branch of the left bronchus, and the branch of the right bronchus to the middle lobe. It will be noticed that the length of the trachea is five inches, and that the cricoid cartilage is the same distance from the upper molar teeth. It is also seen that the first branch of the right bronchus is given off at a distance of one inch from the bifurcation of the trachea, while the left bronchus is two inches long before any division takes place.

of tilting the orifice of the bronchoscope well backwards so as to search any dorsal branch of the main bronchus. Here at once I saw projecting the sharp, black point of a pin making slight excursions with respiration, and with the mucous membrane injected and swollen so as to surround it closely and conceal all view of the stem and head. I seized the sharp point firmly with a pair of forceps, which I then withdrew through the bronchoscope. On bringing the forceps out through the mouth they no longer held any pin. On looking down again into the lung, I saw that the head of the pin had become hitched against the extremity of the bronchoscope, and so dragged from my forceps. Therefore, having again seized hold of the point of the pin, I withdrew the bronchoscope, forceps and pin altogether.

The time occupied was exactly 20 minutes, and this comprised the induction of the anæsthesia and the progressive application of cocaine. I am convinced that the gradual and careful abolition of local sensation was of great importance in this case. There was no frothing of mucus or disturbance in respiration. For the striking success of the procedure I am extremely indebted to the skilful administration of chloroform by Mr. Bellamy Gardner, and the able assistance of Dr. Thompson and Dr. Irwin Moore.

The subsequent history is unimportant. Dr. de Havilland Hall examined the patient next day and found no evidence of any disturbance. There was no cough; breathing and voice were not interfered with; and there were no indications of any traumatism. Fortunately, there was no tracheotomy wound to close and leave a scar. The patient returned home two days later and has remained perfectly well.

The accompanying illustration gives the actual size of the pin removed, and the semi-diagrammatic drawing indicates the situation where it was impacted and the method of reaching it. The distance from the teeth to the impacted pin, as measured by the length of the tube, was 35 centimetres (13¾ inches). The pin had evidently entered a dorsal branch of the division of the bronchus going to the middle lobe. It is hardly necessary to point out that, being head downwards, with the swollen mucosa already closing round the stem, and with the sharp point projecting obliquely into the main bronchus, there was hardly any prospect that the pin would ever have been expelled through the mouth. The hopelessness of reaching a foreign body impacted in the lung has been demonstrated only too frequently. The after-history of a foreign body in the bronchi may be full of surprises. In a few cases it may remain more or less latent for months or even years, and may, in a few fortunate instances, be coughed up. The usual sequel in the vast majority of cases is pulmonary complications and death.

Relief cannot be given too promptly. The pin in the above case had only been in the lung 27 hours, yet it was already rusted in parts. All of it, except the pointed extremity, was concealed and embedded in the swollen mucous membrane. It could not have been long before this point would have been submerged in muco-pus. It has been pointed out by von Eicken that acute pneumonia may be started by a foreign body in the lung within 48 hours. It is well, therefore, to realise that every patient with a foreign body in the upper air and food passages is in danger until the intruder is expelled; that the danger varies with the nature and situation of a foreign body, and is increased when it becomes impacted; and, finally, that even when such a dangerous substance as a shawl-pin is tightly fixed in a secondary bronchus, yet it can be safely and rapidly removed by a method which is bloodless and practically free from all risks. It cannot be hoped that the skill for these delicate manipulations can be acquired by everyone, but there are few laryngologists who cannot carry them out, and the number of these experts is probably as great as that of surgeons who would venture nowadays on the obsolete methods at removal which are rendered unjustifiable since the introduction of Killian's tubes.

The moral for those who are neither laryngologists nor operating surgeons is that for an accident which was only too frequently and inevitably fatal we now have an operation which is almost always safe and successful. A second lesson is that these cases should not be kept from the expert until after the failure of old-fashioned methods. In the above case I had the great advantage of operating in conditions undisturbed by previous interference. Dr. Thompson and Mr. Carless were, fortunately, both decided to "defer no time, delays have dangerous ends."

Remarks by Dr. DE HAVILLAND HALL.—Before commenting upon the purely medical aspect of the case I would like to point out how the wonderful scientific advances made in the lifetime of many of those still actively engaged in practice conduced to its successful issue. In the first place, (1) the *telephone* was called into requisition to make an appointment for the patient to be examined by the (2) *X rays*. She was conveyed from her home to London in a (3) *motor-car*. At the operation general anæsthesia was produced by (4) *chloroform*, and complete local anæsthesia by (5) *cocaine*. Finally, the pin was removed through (6) *Brünings' telescopic tube*. (1), (2), and (3) greatly facilitated the operation, which, however, was only rendered possible by the employment of (4), (5), and (6).

On being called into consultation by Dr. StClair Thomson I pointed out to the patient's friends the grave results which usually attended the presence of a foreign body in the air passages, and they at once gave permission for the performance of any operative procedure which should be deemed necessary. This unrestricted permission seemed to me essential, as, from the position of the pin in the chest, and from my very limited experience of Brünings' tube, I hardly expected that the foreign body would be removed *per vias naturales*. Dr. StClair Thomson has described the various steps of the operation, so that it will be unnecessary for me to say anything about it, except that what impressed me most during its performance was the great importance of a skilled anæsthetist and the absolute necessity for the free use of cocaine to procure complete local anæsthesia. Dr. StClair Thomson demonstrated to me the presence of the pin in the bronchus by means of Brünings' tube, but even after I had seen the pin *in situ* I was hardly prepared for the speedy manner in which Dr. StClair Thomson seized and extracted it. Owing to the delicate manipulations required on the part of the operator, and the collaboration of a skilled assistant in addition to the anæsthetist, this operation must necessarily be left in the hands of those who have the opportunity of frequently using the instruments employed in the operation.

Queen Anne-street, W.

CEREBELLAR ABSCESS AND ACUTE SUPPURATIVE LABYRINTHITIS: DIFFERENTIAL DIAGNOSIS.

BY JAMES HARPER, M.A., M.B., CH.B. GLASG.,
CLINICAL ASSISTANT (LATE HOUSE SURGEON), THROAT HOSPITAL, GOLDEN-SQUARE.

As a complication to aural suppuration, cerebellar abscess is one of the most dreaded conditions with which the aural surgeon has to deal. When one considers the thin barrier of bone which separates the suppuration in an ear from the brain, one cannot help being struck by the relatively small number of cases in which intracranial complications occur. Cases of aural suppuration will go on for years, and, indeed, in some cases for a lifetime, without causing any inconvenience to the patient other than that of a discharging ear. There are other cases in which the patient is continually having symptoms which rouse some anxiety in the surgeon's mind as to there being something more in the case than merely a middle-ear condition. Patients often complain of giddiness and disturbance of equilibrium at various times (during which the ear discharges), but, while these symptoms go and come and are apparently of a passing nature, there are yet many cases in which giddiness and a general feeling of malaise are continually present. In these cases we may have a sudden exacerbation of symptoms and the patient may appear to be acutely ill. Knowing the grave possible complications the surgeon instinctively thinks of some intracranial mischief. The change mentioned above is, as a rule, sudden, and when, in addition to giddiness and disturbance of equilibrium, we have nystagmus added, it then becomes a difficult problem to decide whether this is merely an involvement of the labyrinth, which in itself is a serious enough condition, or whether the suppuration has spread to the cerebellum, thereby setting up cerebellar abscess. Or, again, the surgeon, from the gradual increase in the severity of the symptoms, may have made up his mind already that the labyrinth is involved to a greater or less extent, and he may now have to settle the question whether he has, in addition,

cerebellar abscess. In either of these conditions the patient is acutely ill. Active interference is urgently called for, and the delay of several days in which the symptoms of cerebellar abscess may become more pronounced and allow the surgeon to make a definite diagnosis has often cost the patient his life.

In this short paper a method will be described which is both simple and easy of application, and by which the surgeon will be able to differentiate these two conditions and thus save valuable time.

This method depends for its value on the result of special tests on the labyrinth. By producing mechanical irritation on the sensitive canals definite phenomena are brought about. From a knowledge of those results in health and a comparison with what is found when the labyrinth is diseased, we have been able to make certain definite rules, so that, on the application of these tests, if we find that our results correspond to what we know to be the normal, we can be quite sure that the labyrinth is in a sound condition.

On the other hand, should our results differ from what we call the normal, we are able to form a definite opinion, not only as to the diseased condition of the labyrinth, but also in a large number of cases as to the extent of the disease.

We are greatly indebted to the studies of Flourens in the early parts of the nineteenth century, and to the later experiments of Ewald, for our knowledge of the phenomena resulting from vestibular irritation. Bárány[1] has been able to explain these results by modern methods and to give to them their proper clinical significance. There are three chief methods by which vestibular irritation may be brought about. Two of these attain their object by causing a flow of the endolymph in the semicircular canals. Normally these canals are continually sending impulses to their centre, the geniculate ganglion in the internal meatus, and from there fibres pass to Deiters's nucleus in the medulla, which is connected with the nucleus of the sixth nerve of the opposite side. This nerve controls the external rectus of its own side and the internal rectus of the opposite side in conjugate movements of the eyeball. Now, if this balance between the two sides be upset, the result will be—either one side will have a more powerful action or the other will have a diminished function; in either case we get nystagmus.

Vestibular nystagmus has certain definite characteristics. It consists of two components, (1) a slow movement, and (2) a quick jerky movement. These movements are increased if the eyes be turned in the direction of the quick movement and are stopped if the eyes be turned in the opposite direction. Accompanying this nystagmus, objects seem to fall in the direction of the quick movement. This is produced by the slow movement of the eyes, since there is not sufficient time in the quick movement to produce any impression. Nystagmus is also seen in disseminated selerosis, Friedrich's hereditary ataxia, &c., but in these conditions it is more of a regular, from side to side, oscillation, both components being equal as to time and strength.

There are three chief tests on the labyrinth by which nystagmus is brought about—the caloric, the rotatory, and the galvanic. Of the three, the caloric is the best for our purpose. It is easy of application, only a simple apparatus is required, and the patient need not be disturbed in applying it. In the rotatory test, on the other hand, the patient must be able to sit up, a more elaborate apparatus is required, while even in the hands of skilled investigators results are not always reliable. The third test, the galvanic, though useful, perhaps, in certain cases as confirmatory evidence, is not found to be of much practical value, because as a rule the pain and the discomfort caused by its application make it such that few patients will submit to it. The rotatory test and the galvanic will be described in brief, but the caloric will be described in detail, since it is upon this test that the value of our method depends.

The rotatory test.—The patient is made to sit upright in a revolving chair. This chair is turned round 10 times in 20 seconds. At the end of the turning the patient will be found to have a nystagmus in the opposite direction to that of the turning. Objects will appear to fall to the side of the nystagmus. If the patient be made to stand upright with the heels close together he will fall in the direction of the nystagmus, but will feel as if he were falling in the opposite direction. The direction of the resultant nystagmus depends upon the semicircular canal in which the endolymph is displaced, and Bárány has enunciated the law that the plane of resultant nystagmus will be found to be that meridian of the cornea which corresponds to the plane of rotation. The duration of this nystagmus varies greatly. In one case it will be found to be 5 seconds, and in another as much as 2 minutes. Also both sides will often be found to be unequal as to the time.

The galvanic test.—One electrode is placed on the mastoid and the other is held in the hand of the same side. If the kathodic pole be placed on the mastoid, say, of the right ear, we get a nystagmus to the right, while if the anodic pole be placed on the left mastoid and the other electrode in the hand of the same side we also get a nystagmus to the right. The explanation is as follows: the kathodic current produces a condition of kathelectrotonus, which is equal to an increased excitability. Not only is the labyrinth excited, but also the vestibular nerve in the internal meatus which leads to Deiters's nucleus, and so impulses pass easier to that side. The anodic current, on the other hand, produces a decrease in the irritability of that side and thus the normal stimulus from the right overcomes the weaker on the left side, so that we get a nystagmus to the right. It will also be found that if both electrodes be placed in the middle line, say one on the forehead and the other on the chest, no nystagmus is produced. As an explanation to the direction of the nystagmus, whether to the right or left, it may be here noted that it is the tendency of every normal labyrinth to cause nystagmus to its own side.

The caloric test.—We are greatly indebted for our knowledge of the technique and our understanding of the significance of the caloric test to Dr. Bárány of Vienna. The method taught in his clinic is easy of application and only a simple apparatus is required. If we irrigate the ear of a person with water at the temperature of the body no result will follow; but if the temperature of the water be raised above that of the body, or if it be lowered, nystagmus will result. In the former case nystagmus will be towards the side irrigated. In the latter case it will be towards the opposite side. To carry this out all that is required is a cistern to hold the water, attached to which is a rubber tube with a glass nozzle at the end to fit into the external meatus. When the water is first allowed to flow there is in normal individuals no nystagmus for about 12 seconds and then the movements gradually increase. Should the irrigation be continued too long the patient will complain of giddiness, and in some cases there will be a feeling of sickness.

Bárány's theory as to the cause of this caloric reaction is as follows. He regards the whole labyrinthine cavity as a vessel containing fluid at the temperature of the body. If cold or hot water is brought into contact with this vessel the specific gravity of that part of the fluid nearest the affected wall will be increased or reduced, and thus a flow will be caused in the fluid. Now, the parts of the semicircular canals nearest the inner wall of the middle ear, which are thus the first parts to be acted on by this change of temperature, are the anterior parts of the horizontal canal and the external third of the anterior vertical canal. No flow can result in the horizontal canal owing to its horizontal position, but in the case of the vertical canal there will be a flow and thus nystagmus will result, this nystagmus being of a rotatory type. This explanation is in full accordance with the experimental results obtained by Ewald.

As to what temperature of water is most useful, it will be found that the best results are obtained when the water is at 21° C. or 39° C., according as the nystagmus is desired to be away from or towards the affected ear.

The value of these experiments depends upon the fact that should the canals be destroyed either by a surgical operation or by disease there will be no resultant nystagmus from these tests, and thus the caloric one is of great value in giving us a true indication as to the condition of the labyrinth. As regards unilateral destruction of one labyrinth, this may be caused by suppurative trauma, fracture of the base, syphilis, cholesteatoma, suppuration, &c., but it is to those conditions due to suppuration I wish to devote my attention.

In this short paper I do not intend to enter into a discussion as to the relative merits of the theories of Bárány and Vonstein as to the condition of the labyrinth in chronic suppurative labyrinthitis, but would rather devote attention to those cases in which the question lies between acute

[1] Von Bárány: Physiologie und Pathologie des Bogengang-Apparates beim Menschen.

suppurative labyrinthitis on the one hand and cerebellar abscess on the other.

The symptoms of these two conditions have much in common. As a rule, in both the patient is acutely ill, and, again, in both, for a day or two, the patient may be able to go about, though obviously there is something abnormal in his condition. In both there are disturbance of equilibrium, giddiness, and nystagmus. In both the general condition of the patient as regards pulse, temperature, &c., may be very much alike and the surgeon is forced to delay before coming to a definite diagnosis. Of course, he may make an exploratory operation with a view to finding out the real condition of affairs and dealing with it accordingly, but this is often rather unsatisfactory, since apart from aural suppuration the surgeon may have diagnosed cerebellar abscess, and yet on opening into the cerebellum be unable to find any trace of pus. By a proper use of the caloric test the surgeon should find it a comparatively easy matter to distinguish symptoms due to labyrinthine irritation and that due to cerebellar abscess.

Spontaneous nystagmus due to labyrinthine suppuration has the following characteristics. Up to the third or fourth day the nystagmus may be increased by movement, but after that it gradually decreases until about the fourteenth day it has disappeared. This disappearance of the nystagmus is held to be due to the action of the sound labyrinth; and Bárány explains it thus. He considers the impulses to be made up of three component parts, and since it is the inclination of the normal labyrinth to cause nystagmus to its own side, only one causes nystagmus to the other side. Now, each labyrinth normally balances the other. If one labyrinth be destroyed, the sound labyrinth will overcome that component in the same labyrinth which causes nystagmus to the opposite side. But after a lapse of some time these two components gradually decrease in power until about the end of a fortnight, when they are merely equal to one component, and thus we have no nystagmus.

Now suppose our patient, who has had a discharging ear for some time, is suddenly afflicted with giddiness, disturbance of equilibrium, and spontaneous nystagmus. Obviously he is acutely ill; in all probability he will have taken to bed, and we now wish to decide whether this nystagmus is due to cerebellar abscess or to some labyrinthine affection. The rotatory test is out of the question as it involves so much disturbance of the patient, but the caloric will be of great value to us in coming to a definite decision.

Let us imagine a strong rotatory nystagmus to the right and that it is the right ear that is diseased. With the patient lying on his back sterilised water at 21° C. is allowed to flow in through the external meatus. If after a lapse of from 12 to 60 seconds we do not get a nystagmus to the left, and the nystagmus to the right is not lessened, this nystagmus to the right must be due to some intracranial condition. The absence of the right caloric reaction shows that the right canals must be already destroyed, or at least that their function is lost and that they are no longer capable of sending impulses, and, again, if all this spontaneous nystagmus were due to the destruction of the right canals, it would be to the left and not to the right, and thus we can settle the point that the nystagmus is not due to any labyrinthine condition.

But should the patient have rotatory nystagmus to the left and not to the right, we can again apply the caloric test, but in this case the water must be at a temperature of 39° C., since we wish if possible to create a nystagmus to the right. If we find the function of the labyrinth remains, even though it is impaired to some extent, we must diagnose suppuration of the labyrinth and not cerebellar abscess, but should this spontaneous nystagmus not become less after four or five days we must diagnose cerebellar abscess in addition. Indeed, we may say as a general rule that should the patient have a strong rotatory nystagmus to the right or to the left, and if on application of the caloric test the right canals are found to be capable of being irritated, and if this nystagmus does not get less as time goes on, then it is evident that the cause must be intracranial.

Cavendish-place, W.

DEATH OF A CENTENARIAN.—The death occurred at Langton, near Tunbridge Wells, on April 27th of Mrs. Skinner, who was 106 years of age. She was not long confined to her bed and retained her faculties up to the last. Married at the age of 28 she had eight children.

THE USE OF SOLID CARBON DIOXIDE.[1]

BY EDWARD REGINALD MORTON, M.D. TORONTO, F.R.C.S. EDIN.,

VICE-PRESIDENT, ELECTRO-THERAPEUTICAL SECTION, ROYAL SOCIETY OF MEDICINE; LECTURER ON RADIOLOGY, WEST-LONDON POST-GRADUATE COLLEGE; IN CHARGE OF THE X RAY DEPARTMENT, WEST LONDON HOSPITAL.

ALTHOUGH carbon dioxide was first introduced into therapeutics in a practical way by Pusey of Chicago, I was not aware of this at the time it was brought to my notice by Dr. Geyser of New York in June, 1909. I do not remember being so much attracted to a new therapeutic agent as I was to this, nor do I remember one where extensive application of it has brought out so little that is disappointing and so much that is satisfactory.

In solid carbon dioxide I consider we have the most important therapeutic discovery of recent times, not excluding that remarkable substance radium. This is not to be taken as in any way detracting from radium, few realise more than I do the enormous possibilities it has, but until it becomes cheaper and more plentiful it can never take the place it deserves in the treatment of disease. Carbon dioxide, on the other hand, is both plentiful and cheap, the time of the application is a matter of seconds, the latent period before reaction sets in is one of minutes, the reaction itself is a question of hours, and the whole process is completed in a small number of days. In addition to all this, the application is almost painless, as is also the subsequent reaction, so that even with children no anæsthetic, local or general, is ever necessary; and finally, it is extremely efficient, so much so that in suitable cases it seldom fails. Failure is more often due to faulty technique than to faults inherent to the substance itself. Is there any other agent for which so much can be said?

It is of interest and of value to speculate as to what it is that brings about the beneficent reaction that follows an application.

The temperature of solid carbon dioxide is −79° C., and as the gas under ordinary conditions of temperature and pressure has no local action the effects produced when applied in the form we are now considering must be due to this extremely low temperature, and to this alone. And yet if we compare the results attained by this agent with the effects produced in cases of ordinary frost-bite we are not helped to any great extent. In the latter condition the tissues are as a rule not chilled to more than a few degrees below 0° C., but this mild degree of freezing lasts in most cases that come under our professional care perhaps an hour or may be several hours. On account of the length of time the tissues are frozen we may, and often do, get the most serious results to limb and even to life.

Ordinary freezing lasting only the few seconds necessary to get a very lively reaction from carbon dioxide gives rise to the most trifling effects, so we are forced to the conclusion that the intensity of the reaction following an application of solid carbon dioxide must be the result of the very low temperature to which the tissues are subjected.

I think, however, that a little consideration will show that this very low temperature is quite capable of bringing about all the changes that follow an ordinary application of solid carbon dioxide. As the tissues are cooled through giving up their heat to the crayon, the first effect after freezing point is reached is, of course, that they become rigid. The individual cells, instead of being so many membranous sacs with a fluid or semifluid content, are hard and firm like a dried bean or a pebble. It is conceivable that if the agent were removed at this stage the results would be very slight. In an ordinary application, however, the chilling process goes on to such an extent that those parts next the crayon are cooled to the temperature of the latter, and those lying further away to a lesser degree depending on the distance. Now, as is well known, water and substances containing it to a large extent undergo expansion progressively as the temperature falls below 4° C. If this expansion follows on rigidity the cell structure must suffer mechanical injury. The cell-wall will be fractured, also that of the nucleus; the secondary structure is likewise damaged, and while these injuries will be of perhaps ultra-microscopic dimensions, they

[1] A paper read at the Third International Congress of Physio-therapy held at Paris, 1910.

will be none the less potent to bring about the immediate and intense reaction that follows.

The demonstration of these changes will not be an easy task, but it should be within the capabilities of those accustomed to modern laboratory methods, and in view of the great importance of refrigeration as a local therapeutic agent I commend this research to those who have the time and inclination for work of this kind.

Methods of preparation.—In my original paper[2] and demonstration I advocated the preparation of a crayon direct from the cylinder of the compressed and liquefied gas, and where one has a large number of cases to attend to I still think it is the easiest and most convenient method to employ. I usually make a crayon about 2½ centimetres in diameter and about 12 centimetres long. If this has been properly prepared it will be quite firm and hard, and will last for from one to two hours if left exposed in an ordinary room. With such a crayon I have treated 30 cases in an hour and a half. It must be admitted, however, that the preparation requires a certain amount of skill and practice.

Personally I much prefer the large cylinder of commerce to work with. It contains about 25 pounds of the liquid CO_2 at a pressure of from 200 to 300 atmospheres. Also the cylinder, whatever be its size, must be so disposed that the outlet valve is covered on its inner aspect by the liquid; that is, it must be on a lower level than the rest of the cylinder. To use the cylinder with the valve at the highest point, as some have advised, is not only extremely wasteful, but displays a complete ignorance of the physical properties and aspects of the subject.

The necessary apparatus to prepare a crayon as referred to above are few and simple—viz., a cylindrical ruler, a short cork of the same size, a towel, and two ordinary bandages of about 10 centimetres width.

The towel is first folded lengthwise into three or four, according to the length of crayon desired. It is now rolled around the ruler tightly, so as to form, when the latter is withdrawn, a hollow porous cylinder. The cork is placed in one end of this and the other end is applied over the outlet of the cylinder containing the liquefied carbon dioxide. The bandages are now applied around the towel and over the valve end over end, also making a figure-of-eight where the towel and valve come together, so as to make as tight a joint as possible at this point. This is best done with the valve pointing horizontally. When ready the cylinder is turned so that the valve is pointing downwards, and the valve is opened sufficiently to let the hollow within the towel fill up fairly rapidly. This may be continued until the gas blows out through the bandages and the towel feels hard and firm. The bandages are then removed, the towel is unrolled, and the crayon is ready for use.

This is, in my opinion, the most useful method to employ in hospital work where one has a large number of cases to attend to.

Another method where a smaller number of cases have to be done is the same as above except that no bandaging is done. The towel is held in place with one hand, while the valve is manipulated with the other. As soon as the towel becomes filled with the soft carbon dioxide snow, which is known by some snow being blown out into the room, the valve must be closed. The towel being unrolled, we have a crayon of soft snow, too soft for convenient use. It is made ready by filling a short length of solid-drawn metal tubing and compressing it with a suitable rammer, using a mallet if a very hard crayon is required. In this way we can make up as much or as little as we may want at any time, and the metal tubing in which we mould our crayon may be large or small, and of any section, such as round, square, or hexagon; the latter two are for doing large areas, such as port-wine marks, so as not to leave intervening spaces untreated. This is probably the most useful and convenient of all the methods of preparing carbon dioxide for therapeutic use.

I would like to take this opportunity of showing an apparatus designed by my colleague Dr. W. Hampson, and carried out by the firm of "Aerators, Ltd." In this arrangement are used small cylinders of the liquefied gas, the smaller making only enough for a single case, the larger ones containing sufficient for several cases. They are, in fact, glarified "sparklets." The method of employment is, as you see, very simple and also efficient. It will, I am sure, be of great convenience to those living at a distance or who only require it occasionally.

Dosage.—In considering this question we must remember that in this method of refrigeration we are using a solid crayon, the temperature of which remains constant. Though we describe it as solid, it is yet sufficiently soft that it can be cut to any desired shape with an ordinary pocket-knife. By virtue of these properties, as well as those mentioned at the beginning of this paper, it stands alone and superior to all other refrigerating agents used in therapeutics.

The only two variable factors in dosage are time and pressure. Time is easily measured, and the best degree of pressure to employ in any given case is acquired through experience and practice.

Speaking generally, I find that the pressure should be sufficient to arrest the circulation, and if it also renders the part anæmic for the time being so much the better. The more thoroughly this is done the shorter is the length of the application. The time of the application is usually from 30 to 40 seconds. If the part under treatment overlies a bone the length of the application need not be so long. Care must be taken not to freeze too large an area when applying over a soft part such as the thigh. As pressure is made the surrounding tissues rise up, so to speak, and enclose the crayon, becoming involved in the action of the latter. Probably no great harm is done, but it is not desirable that this should occur.

Effects of the application.—On removing the crayon after making an application the depression persists, gradually returning to its normal contour in a time that varies from two to three times that of the application itself. It appears to depend to some extent on the normal activity of the circulation of the part. The depressed and treated area is found to be pure white and hard, just as if a piece of porcelain had been let into the tissues. When it has returned to its normal contour the surface is seen to be covered with moisture which has condensed upon it during the frozen stage.

The reaction commences almost at once, so that in a very few minutes the treated area is of a firmer consistency and beginning to swell. A wheal quickly follows and a vesicle is formed within an hour, where the application of the crayon has lasted 30 seconds or more. The subsequent changes may be briefly described as a simple, aseptic, plastic inflammation, without gross destruction of tissue. Necrosis may occur if the application has been unduly prolonged, but this is unnecessary and in most cases contra-indicated.

It is incorrect to describe solid carbon dioxide as a caustic, in my opinion. Caustics, strictly speaking, destroy tissue by virtue of their inherent chemical properties; carbon dioxide does not do so. Local death may take place at a later period, but this is not the immediate result of the carbon dioxide or even of the freezing. It is caused by the inflammatory stasis which follows a prolonged application, and this in turn is an essential part of the vital reaction that is provoked.

After-treatment.—While this presents no difficulty we must be careful to prevent septic contamination. Should this happen, the healing process is much prolonged, and the resulting scar unsightly. This agent provides us with a method of setting up a reaction that is independent of sepsis, and our aim should be to maintain this state of things.

The vesicle when it forms should be pricked with a sterile needle and the fluid evacuated. It occasionally happens that the vesicle contains a whitish material that is too thick to flow out readily, but even here the opening of the vesicle will relieve tension and make the part more comfortable. The vesicle may have to be relieved a second or even a third time. Within a few days a crust forms and this should be left alone and allowed to separate of its own accord. This takes place in about two weeks, and the surface is seen to be smooth and of a pink colour, which gets paler as time goes on. The final result is a soft, pliable, and elastic scar of the colour of normal skin as nearly as possible, and in an average case almost unnoticeable after about six months.

It is only during the few days that the vesicle is discharging that any dressing has to be applied. In hospital practice a small circle of lint smeared with boric acid ointment meets the conditions very well. Any antiseptic ointment is suitable, and I have found such preparations as euthymol cream, hazeline cream, and others satisfactory and agreeable. They

[2] THE LANCET, Dec. 4th, 1909, p. 1658.

are to be applied as above and may be dispensed with after four or five days in most cases.

I will now pass on to the results I have obtained by this method of treatment. Most of the cases treated by me have been nævi, of which there were 167. As some of the patients had two or more to be treated, the total number of nævoid growths was 208.

Capillary	134	Stellate	5
Cavernous	51	Lymphatic	4
Capillary and cavernous (mixed)	9	Port-wine marks	5

Capillary nævi.—Of these, 121 cases were completely cured by a single application lasting, as a rule, 40 seconds; 8 had two, 2 had three, and 2 had four applications; 1 case completely cured after three applications was finished off by electrolysis.

Cavernous nævi.—As might be expected, the results attained in this class are not so brilliant, but even here 33 cases were completely cured by a single application; 8 had two, 3 had three, and 2 had four applications; 5 cases were incompletely cured or not benefited, and done by electrolysis.

In those cases where the capillary and cavernous varieties were mixed carbon dioxide was used for the most part, but in most of them there was a deeply seated cavernous part that was more suited to electrolysis.

Port-wine marks.—This still remains the most difficult variety of nævus to deal with, and while I cannot claim to have had results vastly better than can be obtained by other methods, such as radium, the results that can be had by the use of solid carbon dioxide are, in my opinion, as good as any other, and the method is free from most of the objections that can be laid to the usual modes of treatment. Every portion of the mark has to be treated at least twice, and mostly three times. A single application appears to have little or no result so far as taking out the colour is concerned.

Lupus vulgaris.—Quite recently I have had seven cases of this disease to treat, and so far as the immediate results are concerned there is every reason to think that in carbon dioxide we have a means of dealing with this scourge in no uncertain way. In treating these I remove crusts as far as possible and make very firm pressure for at least 40 seconds; a very intense reaction follows, with necrosis of the diseased area. The part must be treated with full antiseptic precautions, and even then the healing process will take from two to three weeks. In all the cases I have referred to complete healing has taken place, and so far as one can tell at this stage the result is a complete success. It is, of course, too soon to say if the cures will be permanent.

Moles and warts.—The application of carbon dioxide is so successful here that it is almost safe to say that there should never be a failure. For a pigmented and hairy mole the crayon should be trimmed to the shape of the growth and applied with firm pressure for from 30 to 40 seconds. In the reaction that follows the pigment is absorbed and the hairs fall out. I am not yet sure if this epilation has any permanence. In treating common warts I do not time the application, but hold the crayon in contact until a narrow zone around the base of the growth is white and frozen. This is essential. In a few days the wart is found to be raised out of its place, and easily separates off.

In conclusion, I wish to say that I am glad to have had an opportunity of relating what I have done with this important and fascinating substance. I hope and trust that my experience will be of use to others, from whom I also hope to learn something more about it before the close of this congress.

Upper Wimpole-street, W.

THE RESEARCH DEFENCE SOCIETY.—It has been for some time felt desirable by the members of the South-West London Medical Society and the members of the Wandsworth division of the British Medical Association that a branch of the Research Defence Society should be formed in the south-western district of London. A joint meeting of the councils of the two societies was recently held and a provisional committee was appointed with Dr. M. G. Biggs as President and Dr. C. M. Young as honorary secretary The subscription for membership is 5*s.* or for associateship 1*s.* per annum, and all inquiries concerning membership should be addressed to Dr. C. M. Young, 115, Broomwood-road, Wandsworth Common, London, S.W.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

Hospital Infection of Tuberculosis.

A MEETING of the Medical Section was held on April 26th, Dr. J. MITCHELL BRUCE being in the chair.

Dr. J. EDWARD SQUIRE read a paper on Hospital Infection of Tuberculosis, as exemplified by the Records of the Resident Staff of the Mount Vernon Hospital for the past 15 years. He said that his paper was an inquiry into the extent of the risk of infection from tuberculosis to members of the resident staff of a consumption hospital, based upon personal examination of all members of the staff of the Mount Vernon Hospital for Consumption and Diseases of the Chest on entering and again on leaving the service of the hospital, extending over a period of 15 years. At present the chief material bearing upon this subject available in reference to the chest hospitals of this country consisted in the report of the staff of the Brompton Hospital for Consumption, drawn up by Dr. Theodore Williams in 1882. There were also some figures from the Victoria Park Hospital and from the hospital at Ventnor. Those reports appeared to be based on inquiries from past members of the staff rather than on personal examination of the chest. The present inquiry, though supporting the view that the risk of infection in a well-regulated chest hospital was very small, showed a larger proportion of cases of probable infection than was shown in the statistics hitherto published in this country. It showed also that a certain proportion of cases of tuberculous infection would be overlooked if they relied solely upon the individuals' account of themselves, several unsuspected cases having been detected as a consequence of routine examination of the chest. It was shown also that a comparatively large proportion of applicants for posts—especially on the nursing staff—showed signs in the chest of previous infection of tuberculosis, and it seemed probable that residence in general hospitals might be responsible for such infection, or at least for the diminished resistance which made infection dangerous. The inquiry was divided into two main divisions, dealing with (1) the incidence of previous tuberculosis in those applying for posts at Mount Vernon, and (2) the evidence pointing to infection during residence there. 14 per cent. of the nurses and 8 per cent. of the maidservants showed evidence on entry of previous infection. That was chiefly found amongst those who had had previous residence in hospital, whether general or special; for while of those who had previously resided in hospital nearly 20 per cent. showed signs of previous tuberculosis, less than 10 per cent. of those who had never resided in hospital showed such signs. The cases of infection while in residence were eight in number, being 2·5 per cent. of all who remained over three months. Two cases of local infection were recorded, one from a splinter and one from a cut.

Dr. C. THEODORE WILLIAMS, referring to the remark in Dr. Squire's paper that the reports of the Brompton Hospital for Consumption appeared to be based on inquiries rather than on examination of the chest, declared that the evidence drawn up in 1882 in regard to the Brompton Hospital was not evidence made up from hearsay. Any nurse to be admitted to the wards of that hospital had to undergo medical examination and remained under the supervision of the resident medical officer. Referring to the probability of residence in general hospitals being responsible for a certain number of cases of infection of tuberculosis, Dr. Williams pointed out that in his report there were two cases of house physicians that ended fatally which came under the category of infection in practice in general hospitals. He emphasised the necessity of recognising the fact that infection of tuberculosis occurred in the porters at chest hospitals who assisted in the post-mortem room.

Sir SHIRLEY F. MURPHY said that it seemed to him that what was wanted was an investigation on similar lines to those followed by Dr. Squire on a like class of persons but not employed in a chest hospital. Until they had the results of such an investigation they were dealing with figures the

actual meaning of which they found some difficulty in stating. He would suggest elementary school teachers as a like class of person for material in the investigation to compare with the nurses in Dr. Squire's hospital at Mount Vernon.

Professor W. OSLER declared that the medical profession was indebted to Dr. Squire for his paper. He (Professor Osler) had no figures to quote, but his general impression was that in general hospitals the doctors, medical students, and nurses were more infected with tuberculosis than were individuals in the general community. The doctors, students, and nurses showed a considerably greater incidence of the disease than occurred in the population at large. There was no question about the fact that medical men who mixed with tuberculous patients became infected with a small focus, but the soil not being favourable for the seed these doctors did not develop into consumptive patients.

Dr. G. A. HERON said that the conditions favourable to infection of tuberculosis were much more strongly marked in the homes of the poor who furnished the class of hospital patients than in the wards of a well conducted chest hospital or sanatorium. He doubted very much whether a well conducted hospital was not really a much less dangerous place in regard to tuberculous infection than the homes of the poor.

Dr. NATHAN RAW said that in regard to statistics his figures were almost in agreement with those of Dr. Squire. He declared that in a well regulated and well conducted sanatorium, or in the open-air wards of a hospital, the risk of infection from tuberculosis was practically *nil*.

Dr. F. J. WETHERED considered that infection from tuberculosis was more likely to occur in a general hospital than in a special one. He pointed out that the public had become possessed with the idea that tuberculosis was so infective that it was unsafe to live near a hospital for consumption.

Dr. SQUIRE replied.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

The Place of Cæsarean Section in the Treatment of Placenta Prævia.

A MEETING of this section was held on April 14th, Dr. H. MACNAUGHTON JONES, the President, being in the chair.

Dr. HENRY JELLETT read a paper on the Place of Cæsarean Section in the Treatment of Placenta Prævia, in which he said that the question to be considered was, Does Cæsarean section lessen the mortality of placenta prævia for the mother or for the child? It appeared to him that there was rather an exaggerated idea of the mortality caused by placenta prævia. During the last 20 years 32,546 women were confined in the Rotunda Hospital, and of these 138 had placenta prævia. Five of these 138 women died, a percentage mortality of 3·6. With a single exception, however, each of the women who died was either moribund from hæmorrhage or in a condition of advanced sepsis when admitted to the hospital. The treatment adopted in these cases was bipolar version, the bringing down of a foot and leaving the expulsion of the child to the natural efforts. Dr. Jellett continued: The cause of death in placenta prævia in the vast majority of cases is one of three things—namely, hæmorrhage, sepsis, or shock. The method of Braxton Hicks in placenta prævia immediately checks the bleeding, and so completely that no other treatment is required. If the patient is already septic when she comes under treatment, dissemination of the infection is probably less likely after the performance of bipolar version than after Cæsarean section. The latter operation, if followed by hysterectomy, might improve the prognosis as regards sepsis, but this procedure is a very formidable one and very likely to prove fatal. If the patient is profoundly collapsed, Braxton Hicks's treatment, carried out under an anæsthetic, is less likely to aggravate shock than Cæsarean section. It would appear, then, that there is only one class of cases in which Cæsarean section may be advisable—namely, that in which it is impossible to carry out the treatment of Braxton Hicks. There appear to be only three conditions which can render bipolar version impossible in an ordinary case of placenta prævia. The first is a rigid and undilated condition of the cervix; the second is where, after rupture of the membranes, the uterus has contracted down upon the fœtus; and the third is where the presenting part is fixed in the pelvic brim. Of these the first is the most important. In such a case it is possible to dilate or to incise the cervix or to plug the vagina. Forcible dilatation of the cervix is contra-indicated because of the danger of tearing in this condition. If, on the other hand, it is possible to make with safety the deep incisions required for vaginal Cæsarean section in these cases, as the upholders of this procedure contend, then the smaller incisions required to enable the introduction of two fingers should present no danger. Plugging the vagina is, however, the best method of treatment in such conditions. The third class of case, in which the presenting part is fixed in the pelvis, is not usually serious. If the hæmorrhage persists it can be dealt with by plugging if the patient is in labour; by rupture of the membranes if she is not in labour; or by extraction if the os is fully dilated. Even if after plugging the vagina the hæmorrhage persists in a case of unavoidable hæmorrhage, bringing down the leg will always check it; and, therefore, this method could be employed with success after, if necessary, a preliminary incision of a rigid and undilated cervix. I may, therefore, sum up my views on the value of Cæsarean section as a means of reducing the maternal mortality. There does not appear to be any place for this operation in the modern treatment of uncomplicated cases of placenta prævia. In a few exceptional cases with a rigid condition of the cervix or premature rupture of the membranes, associated with an unhealthy atonic condition of the uterine muscle, it may be indicated. Such a condition might be treated by the vaginal plug, and, if internal hæmorrhage then result, by Cæsarean section; but, personally, I should be inclined to treat such a case, if plugging failed, by incision of the cervix and the performance of bipolar version. I am unable to see any place for Cæsarean section in the treatment of placenta prævia. What we really require in these cases is an advance in our methods of treating the collapse of hæmorrhage, and the shock, and of combating infection; as thus we could reduce the present mortality and save some of the patients who are apparently moribund when they first come under treatment.

The PRESIDENT having expressed the indebtedness of the section to Dr. Jellett for the valuable paper which they had heard, said that he still believed in the soundness of the principles which he had taught students in the past to follow in the management of the different forms of placenta prævia—the two most important methods being bipolar version and plugging. The most complete summary of the entire subject was contained in the recently published brochure of Dr. Ludovico Moncalvi, Professor Mangiagalli's assistant in the Institute of Obstetrics and Gynæcology in Milan. In 1821 deliveries during the years 1907, 1908, and 1909 there were 45 cases of placenta prævia, with a mortality of six of the latter—four of the fatal cases being central. Bipolar version was not possible in any of these. Sepsis and death followed the one case of Cæsarean section. Professor Pinard of Paris, at the Baudelocque clinic, had informed him (the President) that from 1898–1908 there had been 183 cases of placenta prævia with four deaths, a mortality of 2·18 per cent. No Cæsarean section had been performed, but there had been one Porro's operation in a case of pelvic deformity, with a successful issue. Compare this with the result in Professor Krönig's practice, which he had kindly sent to him from the Freiburg clinic. Out of 40 cases of placenta prævia there had been one death—that is 2·1 per cent. 20 Cæsarean sections had been performed and no death.[1] In coming to any just conclusion from statistics, they should know the accessory conditions which attended on the placental presentation, whether it was central or marginal, the presentation, size, and position of the fœtus, the period and type of the labour, whether a primipara or multipara, or if associated with any deformity of the pelvis.

Dr. HERBERT R. SPENCER said that Dr. Jellett had done well to call attention to the small mortality which attended the performance of bipolar version. The cases which terminated fatally did so as the result of severe hæmorrhage and infection before the treatment was adopted, and would not be saved, but would be further imperilled by the performance of Cæsarean section. He did not utterly condemn the operation, but thought it justifiable in a very few rare cases of central placenta prævia at or near full term with an undilated rigid cervix. Personally, he had seen only one case of placenta prævia in which he thought Cæsarean section would have been justifiable. If, however, the interests of the child were to be placed on the same level as

[1] Vide THE LANCET, April 30th, 1910, p. 1227.

those of the mother—a position he disagreed with—then the use of de Ribes's bag or Bossi's dilator greatly improved the chances of the child surviving. He called attention to the remarkable series recorded by Krönig and Sellheim of 26 cases of placenta prævia treated by Cæsarean section with no maternal or fœtal mortality.

Dr. F. H. CHAMPNEYS thought that in placenta prævia the child must take its chance, and that any special attempt to improve the chances of the child would be at the expense of the mother. He thought it of importance that in any obstetric question the best treatment could be carried out by nature's weapons, in this instance by Braxton Hicks's bipolar version.

Dr. C. E. PURSLOW thought that plugging the vagina, if done efficiently, gave good results.

Dr. AMAND ROUTH agreed with Dr. Jellett that there was no place for Cæsarean section in the ordinary or routine treatment of placenta prævia. An American text-book, recently published, suggested that Cæsarean section might be done when the ante-partum hæmorrhage was uncontrolled by a tampon, where the os was undilated, the woman not much affected by the hæmorrhage, the child at term and living, and the patient uninfected and with a good environment. This would mean that Cæsarean section would become the general treatment of cases of placenta prævia seen in their early stages, and would be undertaken before a sure diagnosis was made and before dilatation of the cervix and Braxton Hicks's method of version had been attempted. This is clearly inadmissible and unjustifiable, but it is quite possible that it would be good treatment in some of the cases described by Dr. Jellett where the cervix was rigid and undilatable. According to Dr. Jellett this condition occurred in 4 or 5 per cent. of all cases. He recalled such a case more than 20 years ago, where serious ante-partum hæmorrhage had taken place in a primipara at a seaside resort. When he reached the patient he found the vagina plugged by the medical man in charge of the case, the external os was closed, and only with the greatest difficulty—after two hours under deep anæsthesia—could he get two fingers in, and eventually was able to bring down a foot and arrest the hæmorrhage. Next morning the cervix was still absolutely rigid, and did not yield for another 15 hours, when the child was born. The cervix was, however, torn, and the patient eventually died from sepsis. If he had had that case to-day, with the added 20 years' experience, he would certainly perform Cæsarean section.

Dr. W. J. GOW thought it important to remember that there were different varieties of placenta prævia, and it was only in a central placenta prævia that treatment by Cæsarean section should be considered. He had performed Cæsarean section for one case of central placenta prævia in which the mother and the child did well. He thought the indications for such a line of treatment were as follows—that the placenta be centrally situated, that the os be small and rigid, that free bleeding occurred on any manipulation, that the surroundings were favourable, that the mother was not in a state of collapse, and that the child was alive and near full term. In post-partum hæmorrhage occurring in cases of placenta prævia he thought it probable that the bleeding generally came from lacerations produced during extraction of the child. Another class of case in which he thought Cæsarean section indicated was when the patient had a purulent vaginal discharge in addition to a central placenta prævia, as this class of case was very likely to be followed by grave septic infection.

Dr. W. S. A. GRIFFITH had performed Cæsarean section for placenta prævia on one occasion with a favourable result for the mother and the child. He thought it monstrous to talk of Cæsarean section as the treatment for placenta prævia except in very rare and exceptional cases. It was only in cases of great difficulty and danger to mother and child that the operation should be performed.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Cases.—Multiple Myelomata.—The Senile Heart.

A MEETING of this society was held on April 28th, Dr. T. R. BRADSHAW, the President, being in the chair.

Dr. JOHN HAY showed a girl, aged 10 years, who for two years had suffered from Complete Paralysis of the Right Arm, hysterical in nature, and accompanied by Charcot's blue œdema. After ten applications of the faradic current complete power had returned to the arm and the œdema had disappeared.

Mr. T. C. LITLER JONES showed a patient from whom he had removed a large Cerebral Tumour from the right Rolandic region. For seven months prior to the operation there had been paralysis of the left arm and leg with twitching in the toes. The cerebration was slow with echolalia. Slight double optic neuritis was present. The operation was done in two stages, much relief following the first stage. The differentiation of the tumour from the brain substance was determined by palpation. Profuse hæmorrhage from the longitudinal sinus was controlled by gauze plugging. The plugging was only gradually removed, being replaced by smaller quantities. The tumour measured 5¼ inches in length and weighed over 4 ounces. It resembled in shape and size a normal kidney. In spite of a fracture of the neck of the left femur from a fall the patient was slowly regaining power. Vision was now unaffected and the mental condition had returned to the normal.—Dr E. E. GLYNN stated that the tumour was a hæm-endothelioma, probably non-malignant.—Mr. RUSHTON PARKER thought that the method of operation in two stages conduced to success.

Dr. O. T. WILLIAMS read a note on a case of Multiple Myelomata in a man aged 37 years. The patient died two months after the first symptoms appeared. Within one month after the onset the first and second ribs on each side had become almost completely absorbed. The sternum fractured at the gladiolo-manubrium, the lower portion pressing on the great vessels and giving rise to a murmur which was audible at a little distance from the chest. The ligaments of the sterno-clavicular joint on the left side were absorbed and the inner part of the clavicle was drawn up into the neck. There was evidence of absorption of bone in the lower cervical and upper dorsal vertebræ. The urine was at first clear and later was quite milky when passed. The Bence-Jones protein reaction was present on most occasions, but at times only a phosphorus-free glyco-protein was observed giving the reactions of mucin. The protein was separated and found to contain a carbohydrate radical and a high percentage of sulphur. The output of ethereal sulphates varied from day to day. The evidence obtained from a study of the protein isolated showed the probability of it being derived from the chondromucoid. The calcium in the urine was much increased and an unusual deposit of sodium urate was found.—Dr. GLYNN stated that the tumour was composed of round cells which were typically myelomatous.—Mr. C. THURSTAN HOLLAND showed and described a series of radiographs of the bones of Dr. Williams's patient which he called one of osteo-psathyrosis, the changes being due to a disappearance of the opaque bone salts. Radiographs of the right and left kidneys showed calculi in both.—The PRESIDENT said that Dr. Williams's case was clearly one of multiple myeloma. A peculiar protein was present in the urine, but he had not found the reactions indicating the presence of myelopathic albumose in the specimens submitted to him, though Dr. Williams had found them in other specimens. He had long held that cases of multiple myeloma with albumosuria were essentially different from those without it and Dr. F. Parkes Weber had lately expressed the same opinion. Cases like the present where its presence was intermittent had not been contemplated. Possibly here there was also the same error of metabolism, but this had been arrested at different stages.

Dr. JOHN HAY read a paper on Certain Aspects of the Senile Heart. The senile heart is a local manifestation of general arterio-sclerosis which in premature senility tends to be focussed in one or other viscus, nor infrequently in the heart. The early manifestations of such a change are of two kinds: 1. Signs of diminished reserve power of the heart. 2. Certain varieties of irregular action; these may be (*a*) extra systoles, (*b*) complete irregularity, (*c*) the alternating pulse. The most important of these is the last. The arrhythmia cannot be taken as any evidence of the extent of the arterio-sclerosis. It may attack a heart which is only moderately affected by the sclerotic change and, on the other hand, advanced cases of cardiac sclerosis may exhibit a regular action even up to death. For practical purposes patients afflicted by this complete irregularity can be classified in three groups: (1) characterised by an insidious onset of the arrhythmia and only slight interference with the

cardiac reserve; (2) paroxysms of irregular action which finally become persistent, with limitation of the field of cardiac response; and (3) serious cardiac failure as the result of the inception of complete irregularity. Typical cases illustrating each group were reported and graphic records demonstrated. The prognosis was dealt with in relation to each of the above clinical groups, and the prognostic importance of the presence of the extra systoles and the alternating pulse was duly considered. Treatment included a careful consideration of the rôle of digitalis in such cases, its dangers and uses.—Dr. H. R. HURTER drew attention to the frequency of cerebral thrombosis in patients in whom the nodal rhythm had presumably become established. He had lost three patients from thrombotic hemiplegia within a few weeks of the inception of the abnormal rhythm; a fourth patient was just recovered from such an attack of hemiplegia. He considered that the liability to this complication should not be lost sight of in formulating a prognosis in any arrhythmia caused by the contraction of the heart originating elsewhere than in the mouth of the great sinus. He corroborated Dr. Hay's statement as to the extreme gravity of the pulsus alternans.—The PRESIDENT remarked that the use of the polygraph had thrown much light on the real nature and significance of the irregular pulse; it was not desirable, however, or practicable to use this elaborate instrument in every case, but the knowledge gained by its use was of the greatest value in the signs elicited by the ordinary methods of clinical investigation.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—Two clinical meetings were held on April 7th and 21st, at which Mr. George Wilkinson, the President, occupied the chair.—Among the cases shown and demonstrations given were the following:—The President demonstrated Bárány's Labyrinthine Tests.—Dr. Herbert Henry showed: 1. A case of Fracture of the Cervical Spine in a man with dislocation between the fifth and sixth vertebræ. The injury resulted from a fall downstairs. Except for some slight local tenderness, no symptoms developed till six weeks after the accident, when the patient complained of stiffness, due to atrophy of the left shoulder muscles. There were now atrophy of the shoulder muscles of both sides and severe nerve root pains. 2. A boy with Atrophic Muscular Dystrophy where there was evidence of transmission through the female.—Mr. W. S. Kerr showed: 1. A woman with Acute Mastoiditis with a large Perisinous Abscess, following an acute otitis, and cured by simple mastoid drainage. 2. A girl with Perisinous Abscess and Thrombosis of the Lateral Sinus. There had been no rigors and the thrombosis was only discovered on operation. The internal jugular was ligatured. 3. A case of Perceptive Deafness with Facial Paralysis and Anæsthesia of the same side and Loss of Taste in the anterior two-thirds of the tongue. No vestibular reaction could be obtained on that side. The condition was evidently one of syphilitic pachymeningitis.—Mr. G. H. Pooley showed cases illustrative of Congenital and Hereditary Abnormalities and Diseases of the Eye, including (1) abnormalities of the palpebral opening: dermoid of the upper lid; (2) abnormalities of the iris; (3) congenital dislocation of the lens in two sisters; (4) medullated nerve fibres in the retina; (5) partial coloboma of choroid and retina; (6) buphthalmos in two cousins; and (7) hereditary diseases, retinitis pigmentosa and nystagmus.—Dr. A. G. Yates showed: (1) A case of Spleno-medullary Leukæmia, showing considerable reduction in the size of the spleen and in the number of leucocytes under X ray treatment; (2) a case of Lichen Pilaris, showing small horny spines surmounting brownish red papules on the face, which is an unusual situation; and (3) a boy with Myoclonus supposed to have been caused by a caning at school.

MEDICO-LEGAL SOCIETY.—A meeting of this society was held on April 26th, Sir John Tweedy, the President, being in the chair.—Mr. Ross Brown opened a discussion on the Legal Responsibilities of Hospital Authorities. He reviewed the decisions of the Court of Appeal in Hillyer *v.* The Governors of St. Bartholomew's Hospital and in Hall *v.* Lees, and the considered judgment of Mr. Justice Walton in Evans *v.* The Liverpool Corporation. The result of these decisions appeared to be that the authorities of public hospitals did not undertake to perform the duties of medical men or to give medical advice, but that they did undertake that the patients should have competent medical advice and assistance. Their obligation was that the patient should be treated only by experts, whether surgeons, physicians, or nurses, of whose professional competence the hospital governors had taken reasonable care to assure themselves. The relation of master and servant did not exist between the governors and the professional staff, and, providing reasonable care had been exercised in selecting a competent staff and proper apparatus and appliances, the governors were not liable for the negligence of the staff. The nurses and others assisting at an operation ceased for the time being to be servants of the governors of the hospital, inasmuch as they were under the sole orders of the operating surgeon, who, until the operation was completely finished, was supreme. The contract of the hospital authorities was not to nurse during the operation, but to supply nurses and others in whose selection they had taken due care. It was a remarkable fact that although some of these great institutions had been actively discharging their philanthropic duties for centuries, and within their walls many thousands of the population were medically or surgically treated every year, it was only quite lately that the law courts of this country had been called upon to discuss the principles governing the relationship of hospital authorities and patients. It was gratifying to find that the result of these judicial decisions was not calculated to discourage or in any way cripple the noble work which the hospitals were doing in the relief of human suffering.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Royal Infirmary on April 19th, Dr. W. Ward-Smith being in the chair.—Dr. W. Mitchell exhibited Skiagrams of the Hand showing undescribed bone changes associated with tuberculous arthritis. The photographs showed a curious striated appearance of the long bones, the meaning of which was as yet undiscovered.—Dr. A. Bronner read notes on (1) a case of Empyema of the Maxillary Antrum operated on by the Caldwell-Luc method; (2) cases of Deviation of the Nasal Septum treated by submucous resection; and (3) a case after Killian's operation on the frontal sinus.—Dr. J. Basil Hall read notes on 53 cases of Intestinal Obstruction. The most noticeable point was the enormous death-rate in the cases of obstruction by band, the reason being that these cases were only seen too late owing to the very deceptive onset of the symptoms. All text-books state that these cases commence suddenly, but experience shows that this is not so. The onset is very gradual, and the symptoms at first are very slight, and it may not be until the intestine is nearly gangrenous that the decisive symptoms appear. Some excellent lantern slides of various specimens were shown.—Dr. Ward-Smith said he thought that visible peristalsis should always be looked for and was a certain sign of obstruction.—Dr. T. Jason Wood agreed with Dr. Ward-Smith, and instanced several cases showing the difficulty in diagnosis.—Dr. Mitchell, Dr. A. H. Bampton, Dr. A. F. Martin, Dr. J. H. Rawlinson, and Mr. F. W. Goyder also spoke.—Dr. Hall then replied.

INVALID CHILDREN'S AID ASSOCIATION.—By the kindness of the Duchess of Marlborough the annual meeting of the Invalid Children's Aid Association (London) Incorporated, 69, Denison House, 296, Vauxhall Bridge-road, S.W., was held on April 27th in Sunderland House. The chair was taken by Her Grace, who pleaded the needs of the association with much force. She reported a new departure in the work of the association by the acquisition of a special home, for which the sum of £500 a year would be required. Towards this amount she promised £200 if a further £300 could be raised. The Bishop of Bath and Wells followed. He dwelt on the need of personal service. Dr. Robert Hutchison and Mr. D'Arcy Power spoke on the medical aspect of the association, and Mrs. Carl Meyer as a member of a care committee made an appeal for workers and funds for the East-End. Miss MacNaughtan enlarged on the need of more visitors for the invalid children. The meeting, which was largely attended, adopted the report of the society, and votes of thanks were passed to Her Grace and the speakers. At the close of the meeting the Duchess entertained her numerous guests at tea.

Reviews and Notices of Books.

The Medico-Chirurgical Series. No. 2: The Stomach, Intestines, and Pancreas. By W. C. BOSANQUET, M.A., M.D. Oxon., F.R.C.P. Lond., Assistant Physician to Charing Cross Hospital and to the Brompton Hospital; and H. S. CLOGG, M.S. Lond., F.R.C.S. Eng., Assistant Surgeon to Charing Cross Hospital, Senior Surgeon to the Evelina Hospital for Sick Children. Edited by JAMES CANTLIE, M.A., M.B., C.M. Aberd., F.R.C.S. Eng., Surgeon, Seamen's Hospital Society, Lecturer on Surgery, London School of Tropical Medicine. London: John Bale, Sons, and Danielsson, Limited. 1909. Pp. 665. Price 12*s.* 6*d.* net.

THE collaboration of a physician and a surgeon to deal with diseases of the alimentary system, which so frequently touch the arbitrary boundary between their respective provinces, should serve to produce a valuable handbook. Dr. W. C. Bosanquet and Mr. H. S. Clogg have carried out their task in a thoroughly satisfactory manner and we can cordially commend the book before us as giving sound and carefully weighed advice in regard to many of the complex problems involved in the diagnosis and treatment of the various maladies with which it is concerned. In their preface the authors state that owing to the limitations of space they have been compelled to discuss these problems briefly and dogmatically, and they deprecate such dogmatism as unscientific, but, in our opinion, their choice of methods has tended towards eclecticism, and the result is a book which is thorough without being unwieldy, affording a practical rather than a mere scientific or theoretical discussion of the subject.

The book is divided into four sections, of which the first is devoted to the Surgical Anatomy of the various organs concerned. The descriptions given, though brief, are clear and sufficient, and are well illustrated by outline diagrams. Three of these, indicating the directions of extension of pancreatic growths in relation to adjacent abdominal viscera, may be mentioned as being especially useful. This section also contains general directions in regard to the examination of the patient, with short accounts of the methods of investigation of the gastric contents and of the fæces. This part is so brief as to do little more than indicate the general methods of qualitative analysis, no reference being made to the quantitative investigation of the gastric contents. In this respect the authors have carried their condensation too far, and we are of opinion that further details in these matters would be an improvement in a subsequent edition.

The second section deals with Affections of the Stomach. A useful account is given of the various conditions grouped under the name of functional disorders. These are differentiated in so far as is possible at present, and the appropriate treatment, both general and symptomatic, is described. The inflammatory conditions affecting the stomach are next considered, and the different forms of gastritis are described. The important subjects of gastric and duodenal ulcers, with their diagnosis and the choice of treatment, are then dealt with in some detail, and useful rules are given in regard to the indications for operation in these cases. These general directions are characterised by sound judgment and are worthy of special note. The various operative procedures are described and illustrated by diagrams. The diagnosis of perforation and of localised suppuration after perforation is carefully discussed and directions for treatment are given. In like manner the clinical manifestations of dilatation of the stomach are described and the choice of medical or surgical treatment is discussed. Another gastric disease which is very carefully considered is that of cancer of the stomach; the importance of early diagnosis is insisted upon and the various modes of treatment and their results are well set forth. Clear accounts are also given of congenital hypertrophic stenosis of the pylorus, of perigastric adhesions, subcutaneous injuries of the stomach, and of foreign bodies in its cavity.

The third section, which is much the largest, concerns Diseases of the Intestines, and owing to the numerous conditions of these structures which require operative procedure is a subject which lends itself especially to the joint medico-chirurgical consideration which is the special feature of this book. Space forbids a categorical review of the various subjects considered, but the difficult and complex condition of intestinal obstruction is dealt with in such a clear and instructive manner as to merit special notice. The classification given by the authors is convenient, their remarks on diagnosis are to the point, while their observations on treatment are throughout practical. Diseases of the appendix and their sequels are, as might have been expected, dealt with at some length. The clinical characters of the various forms of appendicitis are clearly outlined, and the diagnosis and treatment are critically discussed. General rules and warnings well worthy of study are set forth, and the question of removal in a quiescent period is considered. This section concludes with a useful description of the various operations usually performed on the intestines, with diagrams illustrating the methods of excision, suture, anastomosis, and other procedures.

The Pancreas and its Diseases are dealt with in the fourth section. The difficult subjects of acute pancreatitis and pancreatic hæmorrhage are discussed, and in the light of recent statistics the authors advise that in cases of severe symptoms referable to the pancreas the abdomen should be opened. The other diseases and morbid conditions of the pancreas are briefly considered and their diagnosis and treatment are discussed. An appendix contains some specimen formulæ, such as alkaline and acid bitter mixtures, bismuth mixtures, anti-diarrhœics, antacid powders, and iron tonics.

We have already laid stress upon the practical character of this book. It is of convenient size, well printed, and bound in a limp leather cover. It should prove very useful to practitioners in giving advice in regard to the choice of medical or surgical treatment in difficult cases.

Myomata of the Uterus. By HOWARD A. KELLY, Professor of Gynæcology in the Johns Hopkins University; Gynæcologist-in-chief to the Johns Hopkins Hospital; and THOMAS S. CULLEN, Associate Professor of Gynæcology, Johns Hopkins University; Associate Gynæcologist to the Johns Hopkins Hospital. Illustrated by AUGUST HORN and HERMANN BECKER. London and Philadelphia: W. B. Saunders Company. 1909. Pp. 723. Price 35*s.* net.

THAT the preparation of this monograph must have entailed a large amount of labour and time is apparent whether we regard the book itself or consider the amount of material upon which it is based. The total number of cases upon which the authors' conclusions are formed amounts to no less than 1674. In view of the enormous experience obtained by the treatment of such a number of patients, we think the authors were well advised to give us only their own views and not to attempt to review the vast amount of current literature on the subject of myomata of the uterus. The present volume therefore deals exclusively with the work done by those connected with the gynæcological department of the Johns Hopkins Hospital and of the Johns Hopkins University.

Dr. Cullen's book on cancer of the uterus is well and favourably known to gynæcologists, and it is not surprising that the publication of the present work has aroused much interest among all those engaged in this special branch of medicine.

It has already taken its place as the standard work of reference upon the subject, and when we remember the large part played by the Baltimore school in the evolution of many of the operations employed in dealing with these tumours this is not to be wondered at. Dr. Cullen has had the inestimable advantage of watching, and, indeed, of playing his own part in the gradual simplification of the procedures employed for the removal of these tumours, but we doubt if there is any practising gynæcologist in the world who does not owe some debt to the man who, as Dr. Cullen so truly says, has done more almost than anyone else to simplify and to diminish the danger of these operations—his co-author, Professor Howard Kelly. When the Johns Hopkins Hospital was first opened in 1881 many myomata were still considered inoperable, while at the present day to find a tumour which cannot be dealt with one way or another is indeed a rare occurrence. Those of us who are constantly practising Kelly's method of removing fibroid tumours with ease and safety are perhaps prone to forget the debt we owe to his genius and originality of mind. The records of his work which this splendid monograph contains will go far towards rendering any such forgetfulness impossible.

The book contains a complete account of the symptoms, pathology, and treatment of fibromyomata of the uterus, and the detail with which all the more interesting cases are recorded renders it of the greatest possible value. It is well worthy of the high standard we are accustomed to look for in the publications emanating from this source. At the same time, it must be remembered that the staff of the Johns Hopkins Hospital have every possible encouragement to produce good work. They lack for nothing either in the way of equipment or of material, and not only is the clinical part of their work done under the best conditions but they are enabled to complete it on the pathological side with equal facility, while they can have the results of their labours recorded by such artists as those who have taken part in the beautiful production of this volume.

With regard to the pathology of fibromyomata, the point in which perhaps most interest is taken at the present time is the sarcomatous degeneration of these tumours. Is this a possible or a common form of degeneration? The authors' experience is as follows. Of 1400 cases 17 showed definite signs of sarcoma, and in 17 others there were suspicious changes not sufficient to warrant a certain diagnosis of sarcoma. In 13 of these 17 cases the sarcoma was apparently the result of a transformation of the myomatous muscle fibres, and in one further case the sarcoma seemed also to have resulted from an alteration in the muscle fibres. From their experience the authors are impressed with the apparent tendency to sarcomatous degeneration created by the presence of a primary hyaline change. The early cell changes present in a myoma undergoing sarcomatous degeneration are beautifully shown in the series of illustrations Nos. 147 to 155. The possibility of finding sarcomatous change in an apparently simple myoma appears to us the strongest possible argument for treating all cases of fibromyomata by total hysterectomy. The authors recommend that in every case the uterus should be laid open at the time of the operation and the tumour examined carefully. But that even this precaution may fail and that the presence of a sarcoma may be overlooked even in the laboratory, after a much more complete examination than is ever possible in the operating theatre, is well shown by the case alluded to on p. 180. Here two years after a supravaginal hysterectomy the patient had definite signs of intraperitoneal hæmorrhage. At the operation a large irremoveable sarcoma was found developing in the stump of the cervix. On re-examination of the original tumour sarcomatous change was found readily recognisable, although it had been overlooked in the laboratory. It is quite certain that those surgeons who habitually practise supravaginal amputation for fibromyomata of the uterus, even if they follow the plan of opening the tumour at the time of operation—a method which has the great disadvantage of often spoiling the specimen for museum purposes—will overlook sooner or later a case of sarcoma of the uterus. The authors are strong advocates for the so-called subtotal hysterectomy, but we confess that the plan they recommend of opening every tumour on removal does not seem to us a certain method of preventing the occasional mistake of regarding a sarcoma as a myoma, especially in view of the fact that the distinction is often difficult even on a careful examination carried out in the pathological laboratory. No doubt when practised in some ways total hysterectomy is the more dangerous operation, and will continue to be so for the inexperienced operator, but Doyen's method of performing the operation appears to us to overcome certainly most of its dangers, and the question is one which even the large experience of the authors of this work cannot be held to have settled once and for all. For our part, we believe that total hysterectomy will be more and more practised in the future and that it is in reality the better operation of the two, although at the present time possibly, though this is by no means certain, it is attended by a slightly higher mortality.

In some ways more important from the pathological point of view than the certainly sarcomatous tumours are those in which the conditions on microscopical examination were only suspicious. A careful examination of the cases related of this kind should make everyone who is called upon to come to a decision upon this difficult question appreciate what a great degree of resemblance certain degenerating fibroids may bear to malignant tumours. In about 1·7 per cent. of the cases examined adenocarcinoma of the body of the uterus was present with myomata. The suggestion that sterility seems in some way to be associated with the development of cancer in the body of the uterus in these cases appears to be borne out by the table given on p. 275. The statement on p. 277 that when carcinoma of the body exists the chances of infection and death are considerably increased might well be brought forward as a strong argument against the treatment advocated in the same paragraph—namely, supravaginal amputation with subsequent removal of the cervix if the body of the uterus contains a malignant growth, a procedure especially likely to be followed by infection of the peritoneum. However, we do not wish to labour the point of the advantages of total removal of the uterus, and in differing from the authors we must remember the great weight which attaches to any recommendation of theirs in view of their vast experience and of the extremely good results they have obtained. A series of 238 cases in two and a half years with only two deaths, a mortality of 0·85 per cent., is one which is not likely to be surpassed when we remember that the cases are not picked and that the figures include all the cases for those years. The mortality of all the cases from 1889 to July 1st, 1906, was between 5 and 6 per cent., a mortality which the authors regard as high, but one which we think would compare most favourably with the results of any other hospital during the same period.

There are many features in this work which command attention, although we do not specially allude to them. This is because we consider that the book is one to be read by every gynæcologist, and we can promise such readers not only great profit but also great pleasure from doing so. The illustrations are well drawn and well reproduced, and if at times, as it appears to us, the artist has allowed his desire to produce a pleasing picture to get a little the better of his fidelity to nature the results

attained more than condone for any such slight lapses from the strict truth. We are accustomed to look for excellence in any monograph published by the teachers of the Johns Hopkins School and certainly in the present instance we have no cause for dissatisfaction.

A Text-book of Physiology for Medical Students and Physicians. By WILLIAM H. HOWELL, M.D., Professor of Physiology in the Johns Hopkins University, Baltimore. Third edition. London and Philadelphia: W. B. Saunders Company. 1909. Pp. 998. Price 18*s.* net.

TWO years ago the second edition was published, but even in this relatively short time a large amount of new material has been added to the literature of the subject. The author has done his best to revise, correct, or modify imperfect statements in previous editions, to add new facts, and to give an account of new theories or points of view which are characteristic of the present stage of development of the subject. Many new facts acquired by the use of recent physical methods have been added. To take a concrete example, we are glad to see an account of the string galvanometer of Einthoven, an instrument which is finding a wide application in the analysis of many recondite phenomena in living organs. The general arrangement of the text-book remains substantially unchanged. The author has made a judicious selection from the immense mass of material old and new. Such a subject as sleep is more fully treated of than is usual in most English text-books. A knowledge of blood pressure and the methods by which it can be determined in man is of prime importance. The whole question is very fully treated and will well repay perusal both by student and practitioner. There is an excellent account of the musculature of the heart, including figures of the arrangement of the heart fibres, but having regard to the word-picture of the auriculo-ventricular bundle and its asserted importance in cardiac rhythm, perhaps a figure illustrating the course, connexions, and distribution of the *a-v* bundle would have added the visual to the graphic and impressed the facts on the reader's memory.

There can be little doubt that, having regard to the recent researches of Loeb and others, the importance of "ions" must attract investigators, and for this reason we welcome the author's account of Faraday's "Wanderers," or "ions," as they bear on the question of the beat of the heart and other cognate phenomena. The illustrations of blood pressure as shown in tracings by Dawson are excellent. Under the heading "Fixed Adjustment of Rate"—i.e., of the heart—the number of beats of the heart per minute in mice is given as 670, the authority being Buchanan. Having regard to the improvements "in the methods of so-called practical physiology," the student would have welcomed an illustration or two by the X ray method, as applicable to the beat of the heart, the passage of food along the intestine, or the opacity of bone and relative transparency of cartilage.

The chapter on Internal Secretions is comprehensive, suggestive, and well illustrated. The illustrations of the researches of Miss Claypon and Starling on the influence of injections of extracts of fœtus on mammary glands in virgin rabbits, had they been added, would have visualised in a way no description can do the far-reaching effects of "chemical messengers" or "hormones"—the modern realisation of the winged sandals of the messenger of the gods. We have looked for but did not find an account of the organs of voice. Special attention is given to Rubner's recent "Problems," contributions to growth upon the basis of the energy factor.

The work maintains the high standard aimed at by its author, and it is sure to prove both attractive and instructive. Perhaps when the next edition is called for the author will give us in his own and ever interesting manner a chapter on "emotions" in their broad and catholic relations. The work of Sherrington and Mott points the way.

Health, Morals, and Longevity. By GEORGE GRESSWELL, M.A. Oxon. & Cape of Good Hope, L.R.C.P. & S. Edin., L.F.P.S. Glasg.; and ALBERT GRESSWELL, M.A., M.D. Oxon., M.R.C.S. Eng., Fell. Roy. Soc. Med. Bristol: John Wright and Sons, Limited. 1909. Pp. 229. Price 5*s.* net.

THE object the authors of this book had in view in writing it was, according to the preface, to present a short *résumé* of the more important conditions for living a healthy life, considered both from the standpoint of the individual and that of the community. They treat of many factors concerning personal hygiene and public health questions in a popular manner, explaining in clear and simple language some of the technical details underlying them. The subjects dealt with are too numerous to permit of reference to all of them, but among other things chapters are devoted to the germ theory, climate, pain, sleep, nutrition, clothing, soil, education, and death. In connexion with "the germ theory," the rôle of micro-organisms in disease is explained, and the importance of the notification of disease and of adequate precautions against infection is emphasised. In the chapter devoted to nutrition and foods the various forms of food are discussed, and their nutritive value is indicated. The dangers arising from infected or improperly prepared foods are also set forth. The subject of clothing is considered from a common-sense point of view, and some general information in regard to the texture and fabric of the materials used in making clothes is given. Soil and water are discussed at some length, and the methods of water-supply and of the purification of water are described. A number of appendices are given dealing with immunity, phagocytosis, and bovine milk in reference to tuberculosis. The authors are less happy in these than in the remainder of their book, since the necessarily brief descriptions tend to inaccuracy or obscurity—as, for example, on p. 208, in connexion with opsonins, the statement is made that the serum from an infected person is only half as powerful as that of a healthy one. Again, in the appendix on insomnia and narcolepsy it is surely unwise to discuss in a book presumably intended specially for a lay public the administration and dosage of hypnotic and narcotic drugs.

The authors supply a large amount of useful information, and in general they counsel care and moderation in regard to the ordinary circumstances of life. It is possible that their somewhat discursive and allusive style may appeal to a class of reader to whom a book avowedly devoted to hygienic questions might not commend itself.

Emergencies of General Practice. (Oxford Medical Publications.) By PERCY W. G. SARGENT, M.B., B.C. Cantab., F.R.C.S. Eng., Surgeon to Out-patients, St. Thomas's Hospital; Surgeon to the National Hospital for the Paralysed and Epileptic, Queen-square; and ALFRED E. RUSSELL, M.D., B.S. Lond., F.R.C.P. Lond., Physician to Out-patients, St. Thomas's Hospital. With 91 illustrations. London: Henry Frowde and Hodder and Stoughton. 1910. Pp. 364. Price 15*s.* net.

THE keynote of the Oxford Medical Publications has been the practical character of the subjects undertaken. Both this series of volumes, and the smaller one which preceded them, to which Mr. Percy Sargent has also contributed, deal largely with surgery from the most practical standpoint. There are many thousand general practitioners in Great Britain and Ireland, and many more in the Colonies, who are constantly called upon to perform any bold surgery at a moment's notice and under difficult conditions. Such men are well trained and equipped in essentials, are quite apt in

diagnosis, but are liable in the course of years to fall behind in the selection of the best procedure by which to deal with the emergency which presents itself. Here lies the value of the volume before us.

Systematic works on surgery, however encyclopædic, either fail to give the details of procedure for handling urgent conditions, or are so bulky as to render it difficult to find them. The authors have laid down a general principle of great value, not to attempt to offer their readers alternatives, or numerous methods of dealing with acute conditions, but have selected from their own experience and judgment one method for each case, which may not in all cases be the best, but has proved to be one of the best. The tone of advice in procedure is sound and thoughtful throughout, but the most modern, and even tentative methods, are not overlooked. As an instance the treatment of simple fractures is laid down on conservative principles which to some might appear old-fashioned, but the authors explain carefully why treatment without splints is applicable to only selected cases. The best parts of the book are those dealing with acute abdominal conditions and with the surgery of the brain and spinal cord, a province of operation which Mr. Sargent's personal opportunities have enabled him to handle with the distinction of direct knowledge.

The section on the emergencies of acute infective disease is well conceived and indicates the value which attaches to a practical grasp of bacteriology. The use of information in this department is also illustrated by an excellent adage formulated when treating of the subject of serious wounds: "The assumption that the wound is already infected offers no excuse for carelessness in any single detail. The probable presence of micro-organisms in the wound is no excuse for the introduction of others probably of a different kind."

The chapter on anæsthesia is scrappy, for it deals chiefly with spinal anæsthesia and with the dangers and emergencies of general anæsthesia. In contradistinction the account of shock and collapse and the methods of meeting or obviating these conditions is excellent. The illustrations are numerous and admirable, and we are certain that this well-printed, carefully arranged volume will prove of great practical value to its purchasers.

LIBRARY TABLE.

Health's Highway. By R. J. MECREDY. London: Yellon, Williams, and Co., Limited. 1909. Pp. 172. Price 3*s.* 6*d.* net.—This is a book written by a layman and an enthusiastic cyclist which preaches the gospel of fresh air and sunlight. Of the value of these two adjuncts to health there is no doubt, but the difficulty is, for most of us, to obtain them. Still, there is no harm in insisting upon their desirability. Mr. Mecredy gives us enviable accounts of camping-out tours and other forms of fresh-air holiday. His remarks upon the use of alcohol and tobacco are sensible in the main, but his story of a cycle accident is rather dragged in from the temperance advocate's point of view. He fell on his left knee during a path race "and the patella was left absolutely bare, as though the flesh had been punched off it. For five or six weeks I was attended by the late Surgeon Wheeler, and he told me afterwards that had it not been that I was practically a teetotaller and in the pink of condition the leg could not have been saved." Surely a flayed patella without the joint being opened is not so very serious. We can imagine other than teetotallers keeping a limb in such circumstances.

The Practical Medicine Series, 1909. Vol. X.: *Nervous and Mental Diseases.* Edited by HUGH T. PATRICK, M.D., and CHARLES L. MIX, M.D. Chicago: The Year Book Publishers; Glasgow: G. Gillies and Co. Pp. 248. Price 5*s.* net.—In this, the tenth, volume of the well-known Practical Medicine Series are to be found abstracts of many important papers on nervous and mental topics that have appeared during the year, coupled with much that is of comparatively little value. It is true that the apparent aim of the editors is to analyse especially those articles that are of diagnostic and therapeutic significance, and we find here in a handy form abstracts of much of the best work of English, Continental, and American authors. But there are grave omissions, even if the volume is to contain only papers of relative importance. Thus not a single contribution from the English neurological journal *Brain* is analysed. The few pages devoted to mental disease are utterly inadequate, and the selections in this department leave much to be desired. On the other hand, some of the synopses are of entirely secondary importance, and the same may be said of some of the photographs illustrating the volume Seeing that the yearly output of neurological and mental literature is so immense, discrimination is a *sine quâ non* for the success of any analytical compendium of this description.

Where no Man Pursueth: An Everyday Story. By Mrs. BELLOC LOWNDES. London: William Heinemann. 1910. Pp. 352. Price 6*s.*—We must protest against the subtitle of Mrs. Belloc Lowndes's interesting and very clever book. It is not an everyday story at all, but a tremendously sensational drama of the kind that can but rarely happen. The protagonist in this record of a cold-blooded crime is a doctor who commits bigamy, the ulterior object of which felony is to poison the victim of his sham marriage, his real wife consenting in the scheme and collaborating in the attempted murder. Now this is not an everyday story, but a very unusual and extraordinary one, though Mrs. Belloc Lowndes's skill in telling it goes far to persuade us that such things might easily happen. Curiously enough, some fifty years ago one Dr. Smethurst planned much such a crime, and succeeded in murdering the unfortunate woman who thought she was his wife, his real wife, perhaps, abetting; but so far from escaping pursuit the law laid him by the heels at once, and a jury convicted him of a cold-blooded assassination. Smethurst was not hanged, his escape forming a most interesting chapter in forensic medicine,[1] but his experience, at a time when the safeguards against poisoning were much weaker than now, is good ground for the belief that crimes of his sort rarely escape punishment, and cannot be regarded as everyday occurrences. Mrs. Belloc Lowndes has not found in Smethurst's crime the *motif* for her novel; this we happen to know, while in no single detail does her story resemble the tragedy of Miss Bankes's death, but by an interesting coincidence her imagination has hit upon the very complication of bigamy and collusion between the murderer and his true wife which formed the most extraordinary feature in the drama of real life. We recommend "Where No Man Pursueth" to our readers because it is a thoroughly interesting book, and also because the insight into the troubles of the medical life is remarkable. The sketches of the two young doctors, George Glyn, the sound man in whom experience has begotten diffidence, and Peter Whitby, the cocksure and impressionable man, are excellently drawn types of practitioner, and the hideous responsibility which a medical man must take upon himself when he decides to act as though one of his patients were being secretly poisoned is vividly realised. The villain, Dr. Burdmore, we should not have been able to believe in had it not been for the fact that Dr. Edward Pritchard of infamous memory was just such another. We do not intend to say more about the book as, in particular, to disclose the intricacies of the plot might be

[1] THE LANCET, Sept. 10th (p. 268) and 17th (p. 292), 1859.

to spoil it for other readers. All who like a clever sensational novel should get "Where no Man Pursueth," and medical men should know that they will find the medical parts of the book skilfully done.

JOURNALS AND MAGAZINES.

Jahreskurse für Ärztliche Fortbildung. March, 1910. Published by J. F. Lehmann, München. Price 16 marks annually.—This number of the German post-graduate review is one of considerable interest. Professor Fleiner of Heidelberg deals with diseases of the stomach, and after a careful description of the relations of the organ and the methods of clinical examination during life, discusses the problems of digestion and its disorders. The stomach is divided into functionally distinct compartments and this he considers of great importance. In the first place, the region of the lesser curvature may act as a canal leading directly from the œsophagus to the pylorus so that fluids are directed along its course without occupying the fundus. Secondly, the division into a cardiac portion and a pyloric portion which play perfectly distinct physiological rôles is proved by many different observations, and is, of course, permanent. During life and in the upright position of the patient the gastric canal has a J shape which differs somewhat in the two sexes. The long limb of the J is the cardiac part, and the short limb the pyloric. The former serves as a more or less relaxed food reservoir, the contents of which are so arranged that the last swallowed portions lie in the centre of the mass and still remain alkaline, whilst the periphery contains the first received food and is of an acid reaction. The chief active movement in this part of the stomach (apart from vomiting) is a slow diastole which it undergoes on the receipt of food. The pyloric antrum, on the other hand, contracts actively from two to six times a minute, receiving the most fluid portions of the cardiac contents, and passing them on to the duodenum. The regulation of the reflex which opens the pyloric sphincter and its bearing upon pathological processes are discussed at some length. Fluidity of the gastric contents on the one side of the sphincter and alkalinity of the duodenal on the other side appear to be the chief factors in bringing about this relaxation. In regard to motor sufficiency of the stomach, it is considered that, if gastric lavage in the morning produces a clear washing free from food débris of the preceding day, there is efficient motility. The presence of hypersecretion of acid and digestive juices in the stomach is regarded as pointing to the existence of pyloric spasm, which hinders the outflow of the gastric contents and allows an accumulation of secretion. Thus is explained the excess of acid found in cases of ulcer of the pylorus or of the duodenum. Professor Lüthje of Kiel deals with the subject of metabolism and its disorders. He begins with a concise review of the currently accepted theories relating to the normal metabolism of the various foodstuffs. The nature and treatment of diabetes are then discussed. The existence of hyperglycæmia (excess of sugar in the blood) apart from glycosuria and the relation of these two conditions to one another; the relative advantages of various diets in diabetes; the special advantages of oatmeal diet; the desirability of combining a low proteid intake and a diet of low caloric value with the oatmeal feeding; practical suggestions regarding feeding with alternate meals of vegetables and oatmeal are severally considered. For the treatment of threatened acetonuria an oatmeal diet is considered the best, and large doses of alcohol are said to be beneficial. The administration of bicarbonate of soda by the veins or by the rectum is the only possible resource in the coma resulting from acid intoxication. The number is concluded by Professor Erich Meyer of Strassburg with a short review of blood diseases, including a consideration of the circumstances associated with excess of blood, loss of blood, variations in the relative proportion of serum, corpuscles, and hæmoglobin.

School Hygiene: A Monthly Review for Educationists and Doctors.—The first numbers of this magazine have been issued at the modest price of 6*d.* by the School Hygiene Publication Company. Though in the main published in English, it contains an article in German by Professor H. Griesbach, President of the First International Congress on School Hygiene, one in English by Sir Lauder Brunton, President of the Second International Congress on School Hygiene, and one in French by Dr. A. Mathieu, President of the Third International Congress on School Hygiene. These three articles insist on the importance of school hygiene, on the utility of the international congresses held on this subject, and on the necessity of a permanent link to keep up the connexions established by these congresses. The polyglot periodical is intended to voice this view; as Dr. Mathieu remarks, "Ici apparait le bienfait certain de la collaboration internationale." The other contents of the review are thoroughly international. For instance, Mr. C. Edward Wallis, M.R.C.S. Eng., L.D.S., describes the school dental cliniques in Germany. These are not limited to the examination and treatment of decayed teeth, but there is also instruction given to parents at the "Parents' Evenings." Here teachers and parents are gathered together and given lectures and lessons on dental hygiene, so that they may be able to watch the children, and, if necessary, teach them dental drill. An interesting account is given of the measures taken at Schöneberg, near Berlin, to stamp out an epidemic of ringworm. Some 10,000 children were examined and 25 boys and two girls were found to be infected. The old-fashioned treatment of head-shaving and unguents was relied upon, and the class-rooms frequented by the children were disinfected. Teachers and parents after the patient was reported cured kept strict watch for six months in case of recurrence, and the total cost of the measures taken amounted to a little over £900, each patient treated and cured costing about £33. As the sanitätsrat, Dr. Friedemann, remarks, it was a brilliant but expensive victory. Dr. Luther H. Gulick, President of the Playground Extension Committee, New York, deals with athletics for girls from the biological standpoint. He concludes that boys' games, football, cricket, tennis, golf, &c., are all derived from the pursuits and necessities, the hunting and the fighting, by which the primitive man managed to survive. "The ability to run, to strike, to throw, is, on the whole, a masculine ability." He points out that the average boy is stronger than the average girl, except that the girl matures earlier, so that at the beginning of puberty she may surpass the boy of her age in height, weight, and speed. But he suggests that this superiority lasts a very little time, and he holds that the physical exercise and the muscular development of woman must not be conducted on the same lines as those of man. Dr. Gulick maintains that: "So far as the subject has been experimented with, dancing seems to be the form of exercise best adapted to the abilities and needs of girls, and bids fair to take the place in the average girl's education that athletics take in the case of the average boy. Dancing is here used in the large, old sense—the sense in which it was used among the ancient Greeks. The two-step and the waltz do not constitute a leading part of the dancing curriculum."

The Phonographic Record.—The Society of Medical Phonographers was founded in 1894, and its bi-monthly publication has now entered upon the sixteenth volume. The current issue contains, besides the treasurer's report for the year

1909, the continuation of an article by Mr. Norman Porritt on appendicitis and an interesting review of recent continental literature bearing on clinical pathology. A new feature is a student's department edited by Dr. O. C. Gruner. The value of phonography to a medical student or to a practitioner in after-life may be considerable, and we commend the society to the attention of our readers, as we have done on many previous occasions.

New Inventions.

THE "NEBULIQUE" SPRAY.

THE "Nebulique" is the name given to an atomiser or spray which Messrs. C. J. Hewlett and Son, of Charlotte-street, London, E.C., have put on the market, and it appears to us as being one of the best to which our attention has been called. The "Nebulique" produces a fine cloud with either aqueous, spirituous, or oily solutions, and has the decided advantage when required of spraying with only a few drops of liquid. It is suitable for laryngeal, pharyngeal, or nasal purposes, and there are no moveable parts to get out of order. As the illustration may perhaps convey, the spray, with the exception of the lower part, the rubber ball, is made entirely of glass, and thus liquids never come in contact with the rubber. For the sick room the spray will be found to diffuse disinfectants with a good volume, and the apparatus can be removed from the rubber ball and be quickly and easily sterilised by boiling or otherwise. Not the least desirable feature of the "Nebulique" is that it can be obtained for the moderate price of 3*s*.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on Thursday, April 28th, Sir THOMAS BARLOW, Bart., K.C.V.O., the President, being in the chair.

The following gentlemen having passed the required examination were admitted Members of the College: David Henriques de Souza, M.D. Lond., L.R.C.P., Thomas Renton Elliott, M.D. Camb., David Barty King, M.D. Edin., Henry Fairley Marris, L.R.C.P., Geoffrey Eugene Oates, M.B. Lond., Sydney Arthur Owen, M.B. Camb., L.R.C.P., William Trethowan Rowe, M.D. Lond., L.R.C.P., Reginald Vaughan Solly, M.D. Lond., L.R.C.P., and Rawdon Augustus Veale, M.B. Lond., L.R.C.P.

Licences to practise physic were granted to 90 gentlemen who had passed the required examinations.

The following Members were elected Fellows of the College: Otto Jackson Kauffmann, M.D. Lond., Charles Hubert Roberts, M.D. Lond., Edward Arthur Saunders, M.B. Oxf., Francis Edward Fremantle, M.B. Oxf., Robert Dawson Rudolph, M.D. Edin., Lewis Albert Smith, M.D. Lond., Frederick Craven Moore, M.D. Vict., John Charlton Briscoe, M.D. Lond., David Forsyth, M.D. Lond., William Henry Willcox, M.D. Lond., Arthur Frederick Hertz, M.D. Oxf., and Conrad Meredyth Hinds Howell, M.D. Oxf.

A communication was received from the clerk to the trustees of the London Parochial Charities, dated April 7th, concerning the appointment on new terms of a representative of the College upon the committee of management of the Chelsea Physic Garden.

The following motion was proposed by the Senior Censor (Sir WILLIAM ALLCHIN) and seconded by the Emeritus Registrar (Dr. E. LIVEING):—

That the altered scheme of the Charity Commissioners in respect to the Chelsea Physic Garden be approved and its provisions given effect to so far as they relate to this College.

The effect of the new arrangement is that the College has now a separate representative on the committee of management of the Chelsea Physic Garden instead of having one alternately with the Society of Apothecaries.

A communication was received from the Secretary of the Royal College of Surgeons of England reporting proceedings of the Council on April 14th.

On the motion of the Senior Censor (Sir WILLIAM ALLCHIN), seconded by Professor W. OSLER, Dr. Norman Moore was elected Harveian librarian in the place of Dr. J. F. Payne, who had resigned.

Dr. MOORE thanked the College for the honour thus afforded him.

The quarterly report of the College Finance Committee was received and adopted.

A report from the Committee of Management, dated March 22nd, was received and adopted. The report was as follows:—

1. The Committee of Management have considered the recommendations of the General Medical Council which were referred to them by the Royal Colleges, and particularly that recommendation which relates to a compulsory interval of two years between the Second and the Final Examinations. The committee beg to point out that the regulations of the Conjoint Board have, since the establishment of the Conjoint Scheme, required an interval of two years between these examinations, but that in the regulations the two years have been interpreted to mean two winter and two summer sessions. In view of the recommendation of the General Medical Council, the Committee of Management now recommend that the regulation be altered so as to require an interval of 24 months between the two examinations.
2. The committee also recommend that the Bedford College for Women, which has been visited by a member of the committee, be added to the list of institutions recognised by the Board for instruction in chemistry, physics, and biology.

Books and other publications presented to the library during the past quarter were received and thanks returned to the donors.

After some further formal business, the PRESIDENT dissolved the Comitia.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 5th, 1832.

SYDENHAM says, that one half of the diseases of females are dependent upon hysteria. There is no disease in which you will meet with more imposition than in this, and that too in cases where the patient's rank in life, her station, and education, would all lead you to believe such imposition on her part to be quite impossible. Females will sometimes insist upon it that they have a disease. I once heard of a case in which a young lady was said not to have passed a drop of urine for six weeks. She had diuretics and every other stimulant to the urinary organs, but all to no purpose. Her medical man now began to suspect the case was all trick; she was narrowly watched, and it was discovered that she *drank her urine*. I was once shown a very large quantity of gravel which a young lady passed with her urine. It was reported to me that she had violent pains in the back and loins. She had gone through the whole list of medicines usually prescribed for these cases, and by way of doing something, she had been sent to the seaside. Now I do assure you, that the gravel which was shown me was nothing more than sea-sand. The above are cases of downright imposition, and in all such cases as *these*, I would advise you to let the patient and her friends know that you are fully aware that her disease is all imposture, and you will generally find this remark sufficient to cure the worst symptoms. (Excerpt from Clinical Lecture, delivered April 10th, 1832, at St. George's Hospital by Dr. Seymour, on Hysteria.)

UNIVERSITY OF LONDON: UNIVERSITY COLLEGE.—A course of eight lectures on the Chief Animal and Vegetable Pigments will be delivered in the Physiological Institute on Fridays during May and June, commencing on Friday, May 6th, by Dr. S. B. Schryver. The lectures will deal chiefly with the more recent investigations on chlorophyll and with the blood pigments. The urinary pigments and the less important animal and vegetable pigments will also be considered if time permits. These lectures are open to all students of the University, and also to all qualified medical men and other persons who are specially admitted.

THE LANCET.

LONDON: SATURDAY, MAY 7, 1910.

Foreign Bodies in the Bronchi.

WITH the rapid progress in the surgery of the present day the methods of treatment of one decade may become utterly obsolete and even unjustifiable in the next. And we are so accustomed to the advances which are being made that we hardly appreciate at their full value the extraordinary improvements which occur with increasing frequency nowadays. In the present number of THE LANCET we print an account of a case under the care of Dr. STCLAIR THOMSON which affords a striking instance of the success which followed the treatment by the latest method of one of the most serious conditions known to surgery. All who have devoted attention to the surgery of the chest know the difficulty and the extreme danger attending attempts to remove from the bronchi and their branches foreign bodies which have found their way into them. In fact, it is difficult to say whether it is more dangerous to leave *in situ* a foreign body which has fallen into one of the bronchi or to attempt its removal by a cutting operation through the chest wall. If the foreign body is left within the lungs it will sooner or later with almost absolute certainty give rise to severe inflammatory processes. Sometimes an acute pneumonia arises within a few days or even within a few hours. Sometimes weeks or months may elapse before the inflammation begins, but sooner or later some inflammatory process will ensue, and will almost certainly lead to a fatal issue. If an attempt be made to remove the foreign body by a cutting operation through the chest wall the risks are indeed great. The difficulty of finding the body is very real, and the danger of injury to the thoracic contents is considerable, so that surgeons were until recently somewhat averse from undertaking so unsatisfactory an operation. Rarely, very rarely indeed, it may happen that the foreign body finds its way out by the route along which it entered, but the chance of this lucky termination of a serious condition is so small that it would be criminal to trust to it.

A few years ago Professor GUSTAV KILLIAN of Freiburg University conceived the idea of examining the bifurcation of the trachea and its main branches by the aid of direct vision, and for this purpose he devised an instrument which he called a bronchoscope and which he introduced into the air passages through an opening in the trachea. The results of this method were so satisfactory that in the country of its origin it soon achieved no small degree of popularity, and was, in fact, widely employed. By means of this tube it was possible to see even as far as the first bifurcation of each bronchus and minor operations could be performed on them, such as the removal of small growths and foreign bodies. But the operation had the manifest disadvantage that it needed a tracheotomy wound which had to heal later. KILLIAN then proceeded to modify the instrument so that it might be used through the mouth and larynx without requiring the performance of the tracheotomy. In this attempt he succeeded, for it was found that when the head was thrown back a straight instrument could pass through the mouth and down the trachea, and in the same way an instrument could be introduced into the œsophagus. The illustrative plate accompanying Dr. STCLAIR THOMSON'S vivid account of the successful use of the instrument explains the mechanism clearly. The passage of the instrument into the œsophagus is no innovation, for its possibility had been, of course, known for many years to professional sword swallowers who are able to pass the blunted blade of genuinely unjointed swords no little distance down the gullet. MORELL MACKENZIE, MIKULICZ, v. SCHRÖTTER, STÖRK, KIRSTEIN, and others persevered in their efforts to inspect the divisions of the air-tracts, and to pass an instrument intelligently guided by sight along it, but success had to await the employment of cocaine, development in electric illumination, and the discovery of the X rays.

More recently the facilities for viewing the trachea and bronchi have been greatly enlarged by the ingenuity of several laryngologists, the instrument now usually employed being that devised by Dr. BRÜNING of the Laryngological Clinic, Freiburg University. This article, which has been fully described in our columns by Mr. HERBERT TILLEY,[1] consists essentially of a long tube sufficiently small to pass between the vocal cords and long enough to extend from the teeth to the division of the bronchi. By means of a prism a light from a small electric lamp is thrown down the tube and the surgeon is able to see directly the structures which are at the end of the tube. Forceps, probes, and other similar instruments can be passed down the tube so that objects may be seized or otherwise dealt with as they lie at the lower end of the tube. For manipulations such as these anæsthesia is obviously necessary; sometimes local cocainisation suffices, but for the more delicate operations it may be necessary that the patient should be under the influence of a general anæsthetic, preferably chloroform. And even when the patient is chloroformed it is desirable that cocaine should also be applied directly to the mucous membrane of the air-passages so as to abolish sensitiveness and prevent undesirable reflex actions. Every credit must be given to Professor KILLIAN for perfecting a method which is now available for the diagnosis and treatment of many conditions which were until recently beyond intelligent therapeutics, and we hope soon to record cases of its employment in much larger numbers, for undoubtedly what can be done in this direction is not appreciated in this country. We believe that already in 1907 Professor KILLIAN had collected the records of 164 cases in which a foreign body had been removed from a bronchus by the direct method and the patients saved from almost certain death. A great number of these cases were reported from Freiburg, and we cannot think that the inhabitants of South Germany are more given to inhaling

[1] THE LANCET, 1908, vol. ii., p. 1359.

foreign bodies than other people. We can only conclude that the practitioners of Freiburg and its neighbourhood, realising the value of direct bronchoscopy, are more prompt in availing themselves of its advantages for their patients.

We may repeat the salient points of the case which has given rise to these remarks, though Dr. STCLAIR THOMSON'S account hardly needs emphasising. A lady was holding a pin between her lips when something caused her to laugh and the pin disappeared. When no symptoms arose it was imagined that the pin had slipped into the œsophagus, but before long she felt that it was within her air passages, while movement increased the definiteness of this sensation. She was brought to London with all speed and an X ray examination by Mr. A. D. REID showed the pin lying head downwards below and internal to the right nipple. The patient was anæsthetised with chloroform and a 20 per cent. solution of cocaine was applied to the pharynx, larynx, and trachea down to its bifurcation. Dr. STCLAIR THOMSON then passed the Brüning's tube, and after a little search the sharp point of the pin was seen projecting from the opening of a branch bronchus, when by means of forceps it was seized and removed. The time occupied from the commencement of the administration of chloroform to the final removal of the pin was only 20 minutes. From the situation in which the pin was found it may be laid down as practically certain that it could never have been expelled spontaneously, and no reasonable doubt can be felt that within a short time severe pulmonary complications followed by death would have ensued. Such a result may well be called a surgical triumph. At once simple, speedy, and safe, the operation offers a marvellous contrast to the older methods of removal through the chest wall. The procedure sounds extremely simple, but the care and skill required are very great, and the case forms another example of a fact which is becoming steadily more evident, that there are certain methods of treatment which can only be safely and efficiently carried out by those who have the opportunity of acquiring special skill by special practice. Every general hospital should be provided with the latest instrumentarium necessary for the practice of these direct methods of exploring the food and air passages, and the laryngologist who is expert in using them will be the first person summoned when emergencies of this sort reach the hospital.

Malaria in the City of Bombay.

ALTHOUGH the parasite of malaria was first discovered by LAVERAN in 1880 it was not until ten years later that the theory of its transmission by means of the mosquito was established. Since that time measures based on this principle have been carried out in various parts of the world, but Bombay claims the distinction of having been the first city of any great size or importance to attempt to combat malaria by modern methods. In a report[1] recently issued by Dr. J. A. TURNER, the executive health officer for the municipality, an account is given of what has been done in Bombay during the past eight years, 1901 to 1909, respecting the fight against malaria. The disease has existed in the city for many years, the local conditions being entirely in favour of fostering the malady. Many of the poorer inhabitants are malarial subjects capable of spreading the infection, and annually some thousands of poor people from other malaria-infected districts in India flock to Bombay. The city abounds in open wells, cisterns, tanks, stagnant pools overgrown with rank vegetation, and other places where myriads of mosquitoes are constantly multiplying. The population of the municipality is large; the census of 1906 showed the people to number nearly a million. During the eight years in which Dr. TURNER has been struggling to reduce malaria Bombay has been devastated by a continued prevalence of bubonic plague which has carried off more than 103,000 persons in that period. Added to this there have been a times sharp outbreaks of small-pox and cholera requiring the attention of the health department and diverting the services of the staff away from malaria. Above all, it must be remembered that the campaign against malaria was carried out among a native population deeply prejudiced by their religion and customs against the measures urged upon them by the foreigner, even although these measures were framed for the protection of the native against disease and death.

In such circumstances the difficulty of the task was enough to discourage the most undaunted enthusiast. But it is greatly to Dr. TURNER'S credit that in spite of all adverse conditions he steadily persevered in carrying out his antimalarial campaign. The line he took was mainly in the direction of improving local insanitary conditions—draining, levelling, and filling in hollow ground in which water was likely to collect, cleaning out wells and tanks, and endeavouring to get them all covered in, the waging a war of extermination against mosquitoes, and urging the prophylactic use of quinine upon the people. It is not possible, even after eight years, to measure by statistics the amount of success which has been achieved. It has to be remembered that an attack of malaria is not, in most instances, immediately fatal, but that an immense amount of misery and suffering results from it, since it causes rather a chronic condition of bad health which interferes with the victim earning his daily bread, and which often renders him liable to fall an easy prey to intercurrent disease. The corporation of Bombay has not been unmindful of its serious responsibilities regarding this disease. In 1901 certain of its members were deputed to consider the measures necessary for preventing malaria in the city with the assistance of their executive health officer, and in 1905 the council petitioned Government to inquire into the prevalence and causation of malarial and other fevers in Bombay. This investigation was carried out by members of the Government medical and sanitary services, entomological experts, and other competent representatives, who issued a report in 1908, about the time that a wave of epidemic malaria was sweeping over India and extending to Bombay. Early in 1909 a committee was formed by a number of important public bodies in the city, including the corporation, to further investigate the increased prevalence of malaria, and to this committee an expert in malaria was attached, namely, Captain A. G. MCKENDRICK, I.M.S., who, however, was shortly afterwards recalled, and his

[1] Report on Malaria in Bombay from 1901 to 1909. By J. A. Turner, M.B. Edin., D.P.H. Cantab., executive health officer.

place was taken by Dr. CHARLES A. BENTLEY. This expert submitted a detailed report in the autumn of last year. He pointed out that the species of anopheles which served to transmit malaria in Bombay was the Nyssorynchus Stephensi, which breeds readily in wells, cisterns, tanks, tubs, or, indeed, in any water receptacle whatsoever, natural or artificial; whereas in many other places the mosquitoes breed only in natural collections of water, such as streams, ponds, ditches, and puddles. Dr. BENTLEY also pointed out that certain species of culex known to transmit filarial disease were found in Bombay, and also the Stegomyia calopus, which in the western hemisphere is known to spread yellow fever. He formed the opinion that with a proper staff and organisation, adequate powers, and sufficient expenditure, it would be possible to control malaria within definite limits through a systematic mosquito destruction, and for this purpose he advised the creation of a special department working under the control of the executive health officer. He also recommended that if any well was found to be serving as a breeding-place for mosquitoes it should be declared a "dangerous nuisance," and that if any house which had a well in which mosquitoes breed the dwelling should be declared "unfit for habitation."

Dr. BENTLEY'S report may be said generally to support the recommendations made by Dr. TURNER to the corporation, the only point of difference apparently being whether, on the one hand, a special department should be created or, on the other, the health department should continue to carry on the antimalarial campaign. Dr. TURNER'S contention is that until the island on which Bombay stands is converted into a waterless, well-less, and perfectly drained and reclaimed condition, nothing will prevent the breeding of mosquitoes. There seems to be some force in his argument that while carrying out antimalarial measures the health department will be improving the sanitation of the city, and that if his staff were augmented it would be possible to deal more energetically and systematically with the insanitary conditions which are discovered. On the whole, we are disposed to agree with Dr. TURNER that the health department, increased in the number of its staff and supplied with the necessary funds, will be able best to carry on the campaign against malaria as a part of its general duty in improving the local conditions in Bombay. It appears to us that Dr. TURNER deserves great credit for his courageous struggle with malaria during the past eight years, under conditions of serious difficulty, which would have been sufficient to dishearten the majority of men.

Medicine in Fiction.

THE favourable review in another column of a novel founded upon a case of poisoning suggests to us a few remarks upon the position of medicine in fiction, a subject which has been frequently treated in the medical press, in our columns and elsewhere, but almost invariably from one point of view—the view of ridicule. It seems clear from several modern novels that this attitude, if assumed too readily, may easily become unfair, for a considerable number of works of fiction, both in English and in French, have dealt recently with medical problems in an accurate and intelligent manner. The importance of this lies in the proof which is so furnished of the increasing familiarity of the public with the problems of medicine, a familiarity that is displayed by the writers and appreciated by the readers. We have, in fact, here distinct evidence that the public is becoming more alive to the intimate manner in which medicine in its different branches must enter into social life, and the more widely this fact is recognised the better it will be for the medical profession in all its sections.

Most of the criticism which has been passed upon the medicine of the sensational novel has been well deserved, but not sufficient account has, perhaps, been taken of the manner in which the element of medicine is usually employed in the manufacture of the plot of these works. Where the terrible accident, the devastating epidemic, or the hideous poisoning is introduced into the story merely to help the story along, being used as a method of removing superfluous persons, as a background upon which heroic virtue may shine, or to furnish an opportunity for displaying the acumen of the officers of justice—in each or all of these situations it cannot matter much whether the medicine is accurate or no. The public is not seriously deceived by incorrect pathology in such connexions because it is so palpable that the medicine has been moulded to fit the story; and it must be admitted that frequently such adaptation of scientific verity to the exigencies of the drama may lead to a good story, where a rigid use of only the accepted teachings would have ruined the plot. Where medicine is used in this subsidiary or auxiliary manner no great harm can come of absurd statements or deductions—in every other walk of life the sensational novelist takes liberties with the truth. But, it seems to us, inaccurate medicine in fiction may do a great deal of harm where the conditions of the medical life, or questions of medical ethics, or matters of hospital administration, and so on, are wrongfully treated; and there have been several notable examples of this in books which may be forgotten now but which had a vogue not so long ago. Here the false statements made and false impressions created did real mischief, and similar attempts to tell from outside what cannot be guessed from outside will continue to do mischief. The authors deal with circumstances that are supposed to be within the public ken, and with matters on which the public has a right to have a critical opinion, but do not supply accurate information for the construction of a public judgment. Nobody really minds whether a particular villain commits his crime with arsenic or strychnine, or whether the evidence massed against him by the sleuth-hounds of the law is in accordance with the medico-forensic facts. The essential thing is that the crime should be done so that there may be a situation to develop, and that the villain should be identified and traced down. The interest in works of this sort lies in the horror of the action, in the subtlety of the murderer, and in the acumen of the detective, and not a whit in the dosage of the poison; and the story would have the same moral whether the toxicology were right or wrong. The general public feels that the chemistry can only be appreciated by those having expert knowledge, while those possessed of such knowledge are not likely to allow it to be unsettled by any inaccuracies on the part of a novelist. For practical purposes the untrue is here as good as the true. But when we are asked in a

novel to consider the place of medical men in the social scheme, the behaviour of medical men towards their patients, the administration of hospitals and sanatoriums, and so on, the position is totally different. The public is rightly interested in the details of such matters, quite apart from the general scheme of any story in which they may find a place, and the greatest possible damage may be done by inaccuracy.

The question of whether medical episodes and medical scenes are fit subjects for fiction can only be answered in one way. They are. Medicine is closely interwoven with the substance of modern life, and clearly falls within the province of those writers who essay to describe life. Medicine has nothing to lose but everything to gain from those writers who can show how intimately its teachings must influence every sort of social and political development. But where medicine is treated in this manner it is necessary that the writer should be both well informed and conscientious. Moreover, in the light of works which have been recently published by certain London firms, it would appear necessary that the authors should have a higher ideal of decency than sometimes prevails, and a more lively appreciation of the incalculable mischief that can be done by the pornographic work. We do not profess here to discuss in the least how far sex problems can be, and how far they cannot be, dealt with in popular fiction; but of this we are certain—sexual perversion is a pathological subject, and finds its only fit place in pathological treatises. Of course, several of the greatest romancers the world has seen have introduced this subject in different phases into their works. Suppose we pardon these great ones on the ground that their intellect was such as to demand unfettered scope, we may at least ask modern writers to prove that they stand on the same plane as BALZAC before they take the licence of BALZAC.

Annotations.

"Ne quid nimis."

THE CHEMICAL ANALYSIS OF COAL-TAR DISINFECTANTS.

INQUIRIES have reached us as to the exact manipulative details employed in our laboratory in the chemical analysis of coal-tar disinfectants. In reply we may state that the following procedure has been found to give accurate and consistent results. 10 grammes of the coal-tar disinfectant are weighed out and thoroughly shaken or emulsified with 90 cubic centimetres of water. 100 cubic centimetres of a hot saturated solution of baryta are placed in a conical flask of about 300 cubic centimetres capacity, provided with a well-fitting cork. The diluted disinfectant is added gradually about 5 cubic centimetres at a time to the hot baryta solution, the fluid being whirled round vigorously after each addition. When the whole of the disinfectant has been added to the baryta solution the mixture is poured on to a wet filter, is filtered, and the residue washed. The filtrate should occupy a volume of about 300 cubic centimetres. One-half of this volume is placed in a separating cylinder and made acid with hydrochloric acid, which liberates the phenols. The barium chloride solution resulting serves to render the phenols insoluble. 20 cubic centimetres of ether are then added and the mixture thoroughly shaken. The ether is tapped off and placed in a small weighed flask beaker. A further extraction is made with another 20 cubic centimetres of ether which is added to the first extraction. The flask is placed on top of the hot air oven and kept at a temperature of 100° F., and a glass tube connected with the water-pump is suspended just over the surface of the ether. Evaporation is allowed to proceed until the residue just smells of ether, and then the flask is placed on its side in a desiccator over a tray of anhydrous calcium chloride. After a quarter of an hour the flask and its contents are weighed. The weight of phenols or phenoloids multiplied by 2 and by 10 gives the percentage of phenols present in the disinfecting fluid. Next the residue—i.e., the extracted phenols—is dissolved in caustic soda, and the solution is made up with water to 100 cubic centimetres. 5 cubic centimetres of this solution are placed in a 50 cubic centimetres cylinder, about 20 cubic centimetres of water are added, and the mixture is then strongly acidified with hydrochloric acid. A standard solution of bromine in caustic soda is then run in until a permanent yellow colour is produced. The strength of the alkaline bromine solution must be controlled by potassium iodide and decinormal solution of sodium thiosulphate. A convenient strength is a fifth normal solution 1 cubic centimetre = 0·016 Br. The number of cubic centimetres of bromine solution run in to produce the permanent yellow colouration, multiplied by 0·016, by 0·195, by 20, and by 2, gives the bromine value in terms of pure carbolic acid of the percentage of phenols present. The above bromine method avoids adding a large excess of bromine to the phenol, which leads to erroneous results when easily oxidisable phenoloids are present, When pure carbolic acid is present an excess of bromine is immaterial. The process just described can be applied to those disinfectants emulsified with soaps and resins. In the case of emulsions made with gelatin or dextrin the use of baryta is unnecessary, the gelatin or dextrin being first separated by means of alcohol or acetone, as described in THE LANCET report. Experiments made since the publication of THE LANCET Commission on Disinfectants continue to bring out a remarkably definite relationship between the carbolic acid bromine figure and the actual germicidal carbolic coefficient determined by the bacteriological procedure described. As examples may be quoted the following:—Disinfectant A: THE LANCET coefficient, 2·4; coefficient according to $\frac{P-B}{3} = 2·7$.

Disinfectant B: THE LANCET coefficient, 7·7; $\frac{P-B}{3} = 7·7$.

Disinfectant C: THE LANCET coefficient, 6·40; $\frac{P-B}{3} = 6·46$.

P = the percentage weight of phenoloids and B the percentage of phenoloids calculated as pure carbolic acid according to the bromine absorbed. It may be added that preparations have been examined which have yielded 75 per cent. of phenoloids by this process.

THE ARCTIC TEMPER.

UNDER this heading Dr. H. G. Blessing has recently published extracts from his diary of the Nansen Polar Expedition in the "nineties." The onset of this condition seems to be slow but sure; in the first Arctic winter it is unnoticeable, in the second winter it becomes troublesome, and in the third winter it has developed into a pall which clings like a mist about its victims and crushes the spirit of nearly all. The cause of this condition is to be found in the darkness, the monotony of the life, and the complete isolation of the explorers from every sign of life and motion; the mind, in fact, is robbed of every external stimulus, and is slowly starved by this

want. Very troublesome is the extreme irritability of the victims of this condition; the most absurd trifle may raise a veritable storm of rage, and caustic speeches evoke yet more caustic retorts, till the atmosphere is ominously charged. In no other surroundings does the beam in one's own eye become so microscopic, and the mote in one's brother's eye so obvious as in these circumstances, and only in the silent watches of the night does the consciousness of personal failings return and restore the mental equilibrium necessary for an impartial judgment of the failings of others. Even these short periods of impartial self-examination are naturally wanting in those in whom self-consciousness is a congenital defect. As with husband and wife who have long lived together, every thought, every fault, every trick of manner or speech become known to all who are sharing in a Polar expedition, everyone's views on every subject under the sun are common property. Under no other conditions is the truth of the old adage, "There is nothing new under the sun," so forcibly driven home as in the third winter of an Arctic expedition. While the expedition is still in contact with land, or when active progress is made towards a definite aim, all goes well, but when the ship is frozen in, and the only sense of motion is limited to the observation of a line passed through a hole in the ice to indicate the course of the current, the strain begins. Dr. Blessing's prophylactic measures are constant employment and a strict limitation of the association of the officers with the crew. "Birds of a feather flock together," and the democratic infraction of this rule leads not only to loss of discipline but also to discomfort on both sides. For work to be sufficiently varied more room must be given than was available on the *Fram* in 1893, when the maker of a pair of ski had to work in a temperature of −20°. Bookbinding, painting, carving, plaiting, leather work, and carpentering are all useful adjuncts in the wise employment of time, and the forethought of friends which provides presents and surprise packets to mark not only the first but also the later festive seasons in the coming years will be amply repaid by the gratitude of the recipients.

THE TELEPHONE AS AN AID TO DIAGNOSIS.

AT a meeting of the Institution of Electrical Engineers Mr. S. G. Brown has read a very interesting paper on "A Telephone Relay." Primarily Mr. Brown's interest in the subject was the production of a clear and loud-speaking transmitter, to magnify the sounds produced in the ordinary telephone, and thus to render telephony at great distances a practical matter. Eventually he has designed a remarkable accessory to the telephone which incidentally may prove to be a valuable adjunct to the diagnostician. The electric stethoscope in its present form causes the sound of the heart to be three times as loud as in the ordinary stethoscope. If, however, the telephone relay invented by Mr. Brown is attached, the two instruments combined raise the intensity of the sound some 20 times and more. The instrument was tested in a number of diseased heart cases and it appeared to render diagnosis particularly easy and revealed some phenomena only previously suspected. When the instrument was applied directly to the heart the sound of the beats given out in the telephones was uncomfortably loud and easily heard by the patient and all those standing round, and this even when the telephones were in position on the head of the operator. The stethoscope as used increased the heart beats to the almost complete exclusion of the shriller or breathing sounds. The instrument can be so tuned, however, that nothing but the breathing sounds were audible. The passage of the air through the lungs was heard as "the roar of wind through a forest of trees." Replacing the telephone head-piece by a transformer the stethoscope was joined to the ordinary telephone service, and for the sake of experiment the sound of the heart has been transmitted over several miles of telephone line to medical men in various parts of London. The sounds received were as loud and clear, it is stated, as when heard locally. It is suggested that it is now possible for the physician, say, in London, to examine a patient, say, in the country, stethoscopically, and to arrive at a correct diagnosis. The instrument may obviously become of distinct service to the deaf, and the ordinary telephone sounds can by its means be projected into a room so that everyone present can hear. A public performance may thus be reproduced in the hearing of a company of persons present in a room remote from the actual scene.

THE HISTORY OF SQUILL.

IN a recent number of the *Pharmaceutical Journal* Dr. J. Gordon Sharp gave an interesting account of the history of squill. Epimenides, the Cretan poet who lived about 600 B.C., wrote about squill and esteemed it highly. Withering was of the opinion that the name was derived from the Greek verb, *skullo*, meaning to flay, or metaphorically, to trouble, in allusion to the irritating effect of the fresh drug on the skin and mucous surfaces. Steinheil described and named the plant in 1834, while he was living among the Algerian tribe Ben Urgin, and in honour of them he gave it the generic name Urginea. Squill is one of the drugs mentioned in the Ebers papyrus (1550 B.C.). It was well known to the ancient Chinese, Indians, and Arabs, and the latter people made a vinegar and oxymel of squill. Hippocrates (460 B.C.) used it as a detergent for ulcers, and for empyema he prescribed an electuary of which squill was a constituent. He used the entire bulb as a pessary in diseases of women. Pythagoras (about 580 B.C.), a pupil of Epimenides, was so enamoured of the properties of squill that he wrote a treatise on it, and he is credited with the invention of vinegar of squill, while he certainly introduced the oxymel or sweet vinegar of squill into Greece from Egypt. The drug was held by the early philosophers to be "alexipharmic"—that is, antidotal. Pliny (27–79 A.D.) gave an accurate and comprehensive description of the drug, which he valued in "dropsy" and "asthma." He recommended the vinegar for sharpening the eyesight and for expelling tapeworm and other intestinal worms. When boiled he gave the drug as a diuretic, and the chewing of the drug was thought to be good for the teeth and gums. It was also given in affections of the spleen and stomach and in inveterate cough accompanied with asthma. Later, Paulus Æginata (690 A.D.), the last of the great Greek medical writers, dealt with the anthelmintic and other properties of the drug, which at that time had an established reputation as an expectorant and diuretic. In course of time, however, squill fell under suspicion among the leaders of medicine, probably owing to the sickness and vomiting that follow its use. Francis Home (1719–1813), who was professor of materia medica in the University of Edinburgh, was the first to show that squill has an action on the heart. He observed the pulse to be remarkably slow after the administration of large doses of the drug, on one occasion the rate falling to 40. About this time squill became recognised again as a valuable drug, as it was found that in order to produce a diuretic action it was not necessary to produce nausea. Cullen (1789) wrote that the combination of squill with an opiate prevented the emetic and purgative action of the drug, and suggested that the diuretic action might be assisted by the addition of a mercurial preparation. It is interesting to note that squill was administered to the celebrated Dr. Samuel Johnson in one of his later illnesses, and

the efficacy of the medicine may be judged from the following extract from the writings of Murphy, the editor of Johnson's works: "The medicines prescribed were so efficacious that in a few days Johnson, while he was offering up his prayers, was suddenly obliged to rise, and in the course of the day discharged 20 pints of water." It should be added that in Johnson's day the pint was equal to only 12 ounces. In 1785 Withering introduced digitalis to the notice of the profession, and squill gradually lost the first place as a diuretic in cardiac affections. Pereira (1850) came near the truth when he wrote: "Considered with reference to its diuretic effect, squill is comparable to digitalis. But it exceeds the latter in its stimulant influence over the urinary organs." It was not until 1879, when Merck isolated the glucosides contained in squill, that our knowledge of its pharmacology was placed on a scientific basis. Even yet the action of the drug on the heart is too often forgotten in writing prescriptions into which it enters.

IMPURITIES (?) IN TEA.

A CORRESPONDENT writes to us on the subject of tea-drinking. The abuse of tea, he says, is well known to give rise to unpleasant symptoms and to produce sundry complaints. He suggests that much of the tea sold is impure, and grounds his suggestion upon the following observations. Some time ago he had occasion for a large quantity of infusion of tea, and for this purpose he used a number of samples of well-known brands from various vendors. In every instance, after a period of from one to three hours, the infusion became turbid with a sediment at the bottom of the vessel. "In plain English," he continues, "this means that the tea we drink is adulterated or dyed with some substance." We fear that our correspondent is drawing a conclusion from insufficient premisses. Infusions of all teas will become turbid on standing and cooling at various intervals of time. Indian teas become more turbid, and that after a shorter interval, than do teas from China. The cause of the turbidity is the tannin forming a precipitate with the alkaloid, or if very hard water be used with lime in addition. In former days Prussian blue was used for colouring green tea, but the practice, we believe, has almost entirely ceased, and, in our opinion, tea nowadays is one of the least adulterated or "faked" foodstuffs on the market. Moreover, it is subject to careful examination at the port of entry by Custom House experts. Even an infusion of very high-class China teas will show a turbidity after standing two or three days, but this is not due to any impurity or dye any more than is the heavy precipitate which will come down within an hour or so in an infusion of Indian tea. Our correspondent is anxious to hear the experiences of medical men as to the results of their observations on the subject, but we shall be surprised to learn that there is any evidence to support the idea of the widespread adulteration of tea being possible.

OPERATION FOR RIGID DILATATION OF THE THORAX.

IN another column we publish the report of an interesting discussion on Operation for Narrowing and Rigid Dilatation of the Thorax which took place at the German Surgical Congress recently held in Berlin. It was fortunate that Professor Freund was able to open it, since his views on the premature ossification of the costal cartilages are well known. He has previously shown that a hyperplasis with premature ossification of the cartilages brings about a state of rigid dilatation of the thorax. In his remarks he said that narrowing of the upper aperture of the thorax was caused by a defective development of the cartilage of the first rib; this might lead to a derangement of the function of the apex of the lung and thus bring about a favourable soil for the tubercle bacillus. He believed that narrowing might be relieved by resection of a piece of the first rib. He also referred to the emphysematous state of the lung which followed rigid dilatation of the thorax, in which, for purposes of relief, pieces of the second to the fifth costal cartilages might be removed. Subsequent speakers confirmed the benefits from the above operations. Dr. von den Velden reported ten cases of operation for rigid dilatation of the thorax; the post-mortem examinations of patients who had succumbed to intercurrent diseases showed that the gap became closed by a bridge of connective tissue which remained elastic. Dr. Hirschfeld (Frankfort) reported a remarkable case in which he had resected the cartilages in a girl suffering from attacks of bronchial asthma, and when this operation had proved insufficient he had performed resection of the manubrium sterni, which had been followed by complete recovery. The discussion was a valuable one as indicating the experience of surgeons who had performed the various operations and that good permanent results had been obtained. With further trials the true value of the procedures will be placed on a firmer footing, but the operation seem to hold out hopeful chances in cases which are most difficult or perhaps impossible to relieve by other measures.

THE MYSTERY OF MARGATE AIR.

THE study of the therapeutics of climate is a difficult one, and we can only speak in broad terms as to why a given place is suitable for various cases. Why, for instance, is one place bracing and another relaxing? There is no exact scientific answer, but the evidence of experience readily establishes one or the other qualification, as the case may be. The layman knows perfectly well the difference between a district a stay in which soon gives him a feeling of well-being, an energetic temperament, a sense of restored health and vigour, and one in which his indisposition to rouse himself becomes worse, where he soon feels tired and where his mental and bodily fatigue finds no relief. For different cases, of course, both places may have their advantages. The explanation of the difference as to whether a place is tonic or stimulating (bracing) or soothing and sedative (relaxing) rests probably more upon physical than upon chemical facts. The late Sir James Paget once wrote of Margate: "No one can tell what it is in the air of Margate, but practical experience has proved that none better can be found." Enthusiasts say that, as appears to be the case on the veldt, the aerial environment of Margate is aseptic, so that wounds readily heal and surgical cases rapidly mend; it is certain that some pathological conditions, especially in children, are most remarkably improved by sojourn in Margate. It is interesting, therefore, to inquire what it is that confers upon the air of Margate these valuable properties. The chemistry of the air can show but trifling differences from the sea air of other places, its bacteriology is most probably negative as regards septic organisms, while, of course, its physics will be profoundly affected by the great expanse of ocean which practically surrounds the Isle of Thanet. The climate is dry, there is little vegetation in the immediate vicinity, the subsoil is chalk, and, in the words of the medical officer, Mr. Bertram Thornton, "it is not improbable that the large area of foreshore, with its sand and seaweed-covered rocks, may also materially add to the salubrity of the air when the wind sets in from the sea." So far, however, this salubrity has defied analysis, and we still await a scientific explanation of factors which are known to exist, but which we cannot as yet interpret in exact terms. The subject has suggested itself to us by the unanimous testimony given in favour of the air of Margate at the recent annual dinner of the Margate Chamber of Commerce, when the speakers included some well-known writers and

members of our own profession. A word of praise is due to this body for the excellent way in which it is serving the interests of the visitors. The Chamber recognises that the chief asset of Margate is its remarkably restorative air, but the importance of providing for the comfort and the recreation of those seeking this air is not overlooked.

TREATMENT OF DIABETIC GANGRENE BY THE APPLICATION OF HOT AIR.

AT a meeting of the Académie de Médecine of Paris on Feb. 15th M. Dieulafoy described a new method of treating diabetic gangrene which was attended with excellent results. On Sept. 14th, 1909, he saw in consultation a man, aged 64 years, suffering from gangrene of the left leg, which extended as high as two finger-breadths below the knee. The leg was cold and livid and no pulsation could be felt in the popliteal or tibial arteries. The symptoms began with severe pain in the leg on the 12th. The patient had suffered from diabetes for 20 years, and in 12 months had lost 46 kilogrammes in weight. Examination of the urine showed that he was passing 82 grammes of glucose and 30 grammes of acetone in the 24 hours. The general condition was too bad for amputation to be entertained. The patient was in a state of prostration bordering on coma and the pulse was 140 and very weak. A strict anti-diabetic *régime*, injections of cacodylate of sodium and, to relieve the pain and induce sleep, veronal and morphine were ordered. The gangrenous part was treated by the application twice daily of douches of hot air produced by a special apparatus capable of supplying a current of 50 litres of air per minute at temperatures ranging as high as 700° C. This method has been introduced by M. Bonamy, M. Marot, and M. Vignat, who have used it with great success in diabetic gangrene limited to one toe and in perforating ulcer of the foot attended with moist gangrene of part of the foot. In the present case air at a temperature of 300° C. was applied to the gangrenous parts, the temperature being reduced to 100° C. in the neighbourhood of the living tissues. The jet of air was projected a distance of from 5 to 10 centimetres, and each sitting lasted from 30 to 45 minutes. The treatment was not very painful and was well borne. After a week the patient was better, the leg was in a condition of dry gangrene, and there was no odour. The amount of sugar in the urine had decreased to 3·28 grammes in the 24 hours and the amount of acetone to 9·7 grammes. The temperature of the air douche was increased to 400° C., and on Oct. 17th the gangrenous tissues were reduced in volume, blackish, dry, and odourless. The hot air not only dried up the surface of the gangrenous part but penetrated deeply, so to speak "cooking" the limb. On Nov. 17th the treatment had to be suspended for two days as the apparatus got out of order, and the gangrenous part became moist and gave off a fœtid odour. On the 19th the douches were resumed at a temperature of 400° to 500° C., and the gangrene again became dry, the fœtor disappeared, and a line of demarcation formed below the knee. The line of demarcation deepened and the gangrenous parts separated from the sound ones. The leg and foot retained their form, but were much diminished in size, black, and shrivelled up, like the limb of a mummy. The tibia was bare at its upper part and a large "window" formed between the tibia and fibula. The patient regained his strength, and on Dec. 21st sugar and acetone had disappeared from the urine. Amputation was performed at the junction of the lower third with the upper two-thirds of the thigh. The femoral artery was found atheromatous and completely blocked by clot. Union of the wound took place by first intention and recovery was uneventful. In the amputated limb the popliteal artery was found obliterated by arteritis and an adherent clot. The clot was a little organised and contained newly formed blood-vessels and some connective tissue. There was no trace of infection, no small-cell infiltration, and no lymphangitis. In contrast to this case M. Dieulafoy related a case of diabetic gangrene of the foot which after three months became moist and fœtid. Amputation was performed in the lower third of the thigh. The femoral artery was not atheromatous and contained no clot. The anterior tibial artery was obliterated by endarteritis and a stratified organised clot. The posterior tibial artery was obliterated by organised clot and its inner coat was completely destroyed. The vessel was both filled and surrounded by small-cell infiltration and was accompanied by lymphangitis. The vascular lesions in the two cases were similar, but in the one treated with hot air the gangrene remained dry and was not followed by infection, while in the other the life was jeopardised by consecutive infection. The hot-air treatment prevents this infection and eliminates the dangers of septic intoxication and septicæmia.

LA REVUE MÉDICO-SOCIALE: A STORY OF TEMPERANCE.

UNDER the editorship of Professor O. Laurent there is published in Brussels a monthly periodical entitled *La Revue Médico-Sociale*. It has for its subtitle "Clinique et Hygiène Sociale." Undoubtedly this title covers a field of news and of research which is of growing importance. At Budapest last autumn Professor Landouzy spoke of social medicine as the newest and most promising development of medical science. It was no longer a question of treating a patient here or there, but of practising curative as well as preventive medicine on entire communities. Medicine, in so far as it affects not merely individual patients but the inhabitants of a district, a town, or a country, is a subject of study which has unlimited possibilities. Whether the publication before us covers even approximately this ground is another matter. Its contents are largely technical and clinical, whereas an organ dealing with the social measures and reforms that act upon the health of the people should certainly contrive to be understanded of those people. Most of the articles in what is a sort of review of reviews are extracted from medical contemporaries—whose editors, we presume, have no objection—and deal with treatment, only a few being of more general or social interest. On the old problems of abstinence from flesh food and alcoholic drink a temperate view is taken. Dr. Gottschalk has pointed out that vegetarians involuntarily pay homage to the meat eaters by trying to imitate meat dishes with vegetable substitutes, but he found *bœuf à la mode végétarien* "absolutely execrable." He recognised that there are meat extractives which might excite the nerve cells and acting as stimulants might, if taken regularly, create symptoms similar to alcoholism. In this connexion he now says that the morbid craving for alcohol is noticeable especially among those who are badly or insufficiently fed; and this happens quite as often among vegetarians as among others. A form of total abstinence of which everyone must approve is described—viz., the manifesto issued by 20,000 Swedish workmen during the recent general strike. Out of a total population of less than 5,000,000 more than 250,000 workmen remained on strike for five weeks. The most perfect order prevailed the whole time in spite of the animosities and bitterness of feeling resulting from the struggle. At the most critical moment the manifesto of the 20,000 workmen was issued appealing to the working class to abstain completely from all alcoholic drinks till the strike was concluded. Encouraged by this popular demonstration, the Swedish Government ventured to advise all the local

authorities to close the drinkshops. This recommendation was adopted in most places, and the sale of beer at meal times in restaurants alone was sanctioned. The Swedish papers publish figures that show the result of these measures. During the month of August, 1908, there were 1549 persons arrested and tried for drunken and disorderly conduct at Stockholm. In August, 1909, there were only 169 such cases. In Gothenburg, the second most important town of Sweden, which as a seaport town is more frequented by intemperate persons than an inland town, there were 647 persons arrested for drunkenness in August, 1908, and only 113 in August, 1909; 188 in the first week of September, 1908, and 3 during the corresponding week of 1909. But, on the other hand, from Sept. 8th to 19th, 1908, there were 249 arrests for drunkenness, and during the same period in 1909, the strike being then terminated, there were 259 arrests. The actual improvement seems to have been only temporary, but some permanent good may have been achieved, while the possibility of abstinence was demonstrated and a wise example given which might well be followed universally in moments of great public excitement when excesses and consequent breach of the public peace are imminent.

THE PATHOLOGY OF MELÆNA NEONATORUM.

THE condition to which the name of melæna neonatorum has been applied is one of considerable rarity, occurring about once in 1000 births. It is also one of very grave prognostic outlook, since according to the statistics of Silbermann death occurs in 56 per cent. of the cases. Although its occurrence is well recognised, its etiology and pathology are still obscure. An interesting paper by Dr. Hermann Schöppler appears in the *Centralblatt für Allgemeine Pathologie und Pathologische Anatomie* of April 15th, in which two fatal cases are recorded with descriptions of the post-mortem appearances and of the histological changes found in the organs. The first case was that of an infant born of healthy parents. On the second day after birth several evacuations of dark blood were passed per rectum, and three more during the night. On the following day only one dark red motion was passed, but the infant became very weak and anæmic and died on the fourth day, having also on that day passed a dark blood-stained stool. At the necropsy the stomach was found to contain dark black blood, the mucous membrane was blood-stained, and after washing with water showed some linear blood extravasations, but no ulceration or excoriation. The whole of the intestine contained thin, fluid blood of dark reddish colour, and in isolated places blood extravasations were seen in the ileum, jejunum, and colon, but nowhere was any loss of substance of the mucous membrane demonstrable. The liver was anæmic, enlarged, and of greyish-yellow colour. The portal vessels showed no peculiarities. Microscopical examination of the stomach failed to reveal any defects in the epithelium or any signs of inflammation. In the mucous membrane of the intestine there were, however, abundant round-cell infiltrations. The submucous tissue was the site of hæmorrhages and the blood-vessels were distended with blood. No abnormal appearances were found in the liver. The second infant was born of a healthy mother, without any history of hæmophilia, and was apparently strong and healthy at birth, but on the eighth day began to pass stools of thin, bright red fluid blood. During the night the infant passed four more, and next day appeared pale and ill-looking, with a subnormal temperature. After passing numerous stools, some bright red, others dark red in colour, the child died in the evening. At the necropsy appearances similar to those described in the previous case were found. Microscopically the stomach showed no abnormal appearances, but in the intestine the epithelium was found to be wanting in small areas, and abundant collections of small round cells were everywhere visible, giving the whole mucous membrane the appearance of inflammatory infiltration. Hæmorrhages were found immediately under the muscularis mucosæ and the vessels of the submucous layer were engorged with blood. In view of these observations the microscopical appearances in both cases were regarded as suggestive only of parenchymatous hæmorrhages. Dr. Schöppler reviews in a brief but interesting manner previous work upon this condition. The earliest observations of note upon it were those of Landau in 1874, who attributed the loss of substance usually observed in the mucous membrane to the effects of emboli, originating in the umbilical vein. Various other views have been suggested, including the following: asphyxia, pathological increase of a physiological intestinal catarrh, the hæmorrhagic diathesis, and the congestion in the portal and hepatic circulation brought about by the changes in the circulatory system at birth. It is the last explanation which Dr. Schöppler favours. He believes that the ligature of the cord leads to acute hyperæmia of the stomach and intestines, and that in conditions of defective resistance this hyperæmia, together with the further irritation induced by food, leads to inflammation and to fatal hæmorrhage.

UNSEASONABLE OYSTERS.

AN important point was raised by Sir F. Flannery when he asked the Parliamentary Secretary to the Board of Agriculture in the House of Commons last week whether, in view of the near approach of the months of May, June, July, and August, during which native oysters could not be lawfully sold in this country, but during which foreign oysters were freely imported, steps could not be taken to protect the community from foreign oysters which are no more seasonable than British oysters. Sir E. Strachey replied that the Government were not prepared to introduce legislation with a view to protect the home oyster industry from legitimate foreign competition, but if oysters are imported which are unfit for human food steps can be taken for the protection of consumers. We are not aware that oysters imported into this country are submitted to any kind of systematic examination before they reach the consumer, and the probability is that not before mischief was done would any steps be taken. The close time for oysters is, as a matter of fact, only to protect the breedings of real natives. If prosecutions for the sale of natives are withdrawn during the close season it will very quickly diminish the supply of British oysters and send them up again to the prohibitive prices of the later "seventies"—a consummation which will be deplored by all lovers of the delicate mollusc. It is obvious that the importation of foreign oysters during the spawning season is carried on to the detriment of the foreign beds, although these beds may be very large. In the case of British oysters the grounds would most probably be ruined if the oysters were allowed to be sold during the close season. It is the better-class consumer who is the patron of the British cultivator and he is only just recovering faith in the safety of oysters—a faith, however, which may easily be shaken again if the promiscuous consumption of foreign oysters is encouraged. If again typhoid fever is traced frequently to the oyster a much more serious "set-back" to the consumption of the oyster than heretofore will occur. This would be a matter for the greatest regret, since British beds are now being very carefully protected from sewage contamination, and there are few foreign beds that receive this protection. It seems to us, therefore, that it is vital that the close time in Britain should be jealously preserved, and

during this time the consumer should take care not to touch an oyster, unless he appreciates fully that he is eating an imported article.

ENTERIC FEVER IN A HÆMOPHILIAC.

IN the *American Journal of the Medical Sciences* for April Dr. C. W. Larned has reported an interesting case in which enteric fever occurred in a hæmophiliac. The patient was a man, aged 40 years. His father, who was living, gave a history of hæmophilia from boyhood until the age of 23 years, when the tendency to hæmorrhage seemed to have ceased. One out of three paternal uncles was similarly affected. The paternal grandmother was a hæmophiliac and died from hæmorrhage during a confinement at the age of 39 years. The patient had frequent attacks of epistaxis in childhood, which at times were so severe as to cause fainting. After the age of 15 years the attacks became less severe but only slightly less frequent. When he cut himself there was difficulty in arresting the hæmorrhage. In 1902 he was operated on for ingrowing toe nail and nearly bled to death. The attack of typhoid fever began in January, 1908, with headache, diarrhœa, and epistaxis which occurred almost daily. He was admitted into hospital on Feb. 2nd with a temperature of 102·5° F. The temperature ran the ordinary course and six days later reached 103·6°, but did not permanently become normal until March 23rd. Rose spots appeared on Feb. 8th and the Widal reaction was obtained on Feb. 15th. Epistaxis occurred once on Feb. 11th, 22nd, 26th, and on March 1st, 4th, and 10th. There was no blood in the stools at any time. The coagulation time of the blood, taken with Boggs's instrument, was 18 minutes (the normal limits being six to eight minutes). Under calcium lactate the time could be reduced to nearly normal in three or four days, after which it lengthened in spite of the continuation of the treatment. The patient was discharged in good condition on April 2nd. It is noteworthy that no intestinal hæmorrhage occurred. Dr. Larned attributes the successful termination of the case to the fact that at about the age of 40 years the hæmorrhagic tendency abated. This appears to be the only case on record of enteric fever in a hæmophiliac. Another point of interest is that the hæmophilia was inherited from the father.

THE FEEDING OF SCHOOL CHILDREN.

A REPORT of considerable interest has recently been issued by the Board of Education,[1] dealing with the results so far obtained from the Act sanctioning the provision of meals to necessitous school children. With some parts of the report which are not of immediate medical importance, such as the mechanism for supplying the food and of recovering the cost from parents, we cannot here deal; nor does the question of the improvement in the manners of the children brought about by supervision at meal-times fall within our province, though we may express a hope that it may prove to be a factor which "emollit mores nec sinit esse feros." Interesting information is, however, given as to the composition of the meals supplied and the cost of the food. It would seem that most education authorities supply a midday meal or dinner, but that some prefer to give breakfast, presumably on the principle that the child should start its school-day with a due supply of fuel for its vital mechanism. Sample diets are quoted in the report, in which are found such items as Irish stew, Yorkshire pudding, Scotch broth, roly-poly pudding, oatmeal porridge, and so forth; and it appears that a fair meal can be provided for a 1*d.* or a little over this amount. Indeed, at Birmingham, which seems to get specially good value for its money, a diet supplying 625 calories cost only 0·91*d.* This is due to the fact that, as is pointed out by the school medical officer, Dr. G. A. Auden, the carbohydrates and fats form the most important ingredients, supplying as they do most of the necessary heat and energy, only a small quantity of the more expensive proteid matter being really essential. A second point of interest dealt with in the report is the question of the effect of the meals provided upon the health of the children. There is a considerable preponderance of opinion that the results have been markedly good, definite bodily improvement and gain in weight being noted in children previously ill-nourished and backward. The report recognises—and, indeed, it is self-evident—that it is essential for the school authorities to administer the Act in coöperation with the medical officers who are responsible for the health of the children. When measures have everywhere been adopted to ensure this coöperation we can have no doubt that an important step forward will have been taken towards the attainment of a reasonable standard of physique among the children of the poor, which has in too many cases been sadly wanting up to the present time.

[1] Report on the Working of the Education (Provision of Meals) Act, 1906, up to March 31st, 1909. Board of Education, Cd. 5131. 1910. Price 3*d.*

SPINAL ANÆSTHESIA.

IN an annotation in THE LANCET of April 23rd upon Jonnesco's method of spinal anæsthesia reference is made to the death of a native reported in the *Indian Medical Gazette* in whom injection of one decigramme was used in conjunction with strychnine, and below this reference we alluded to a death having been reported from the General Hospital, Birmingham. It has been pointed out to us that readers of the annotation might infer that the use of novocaine led to the fatal result in one or other or both cases. It should, therefore, be mentioned that in the *Indian Medical Gazette* the fatality was clearly attributed to the excess of strychnine employed, while in the case of Birmingham the injection consisted of stovaine and strychnine.

AT the next election of members of Council of the Royal College of Surgeons of England there will be three vacancies; one of these is caused by the death of Mr. H. H. Clutton, and the two others result from the termination of the period of office of Mr. John H. Morgan and Mr. C. B. Lockwood. We understand that Mr. Morgan does not intend to offer himself for re-election, but Mr. Lockwood will stand again. We believe that Mr. Bilton Pollard, Mr. J. Bland-Sutton, and Mr. J. Ernest Lane will be candidates at the approaching election.

A TELEGRAM from the Governor of Mauritius received at the Colonial Office states that for the week ending April 28th 1 case of plague was reported, and that there was 1 death from the disease. A telegram from the Acting Governor of Hong-Kong, received at the Colonial Office on May 2nd, states that for the week ending May 1st there were 3 cases of plague and 3 deaths from the disease.

A MEETING will be held on Tuesday, May 10th, at the Mansion House in support of the fund for new chemical laboratories in connexion with University of London, University College. The speakers will include the Earl of Rosebery, Chancellor of the University; the Earl of Cromer, Lord Avebury, Professor Sir William Ramsay, Sir Henry E. Roscoe, and Sir Felix Schuster.

Lord Strathcona and Mount Royal will preside at the festival dinner of the Metropolitan Hospital, which will be

held on Monday, June 20th, at the Whitehall Rooms, in aid of an urgent appeal for funds on behalf of the institution.

THE Princess of Wales will lay on July 14th the foundation-stone of the Barnato Joel Charity which is to be established in connexion with the Cancer Charity of the Middlesex Hospital.

ROYAL ACADEMY OF ARTS.

THE one hundred and forty-second exhibition of the Royal Academy of Arts was thrown open to the public on Monday, May 2nd. Of particular interest to our readers are No. 106, a portrait of Dr. Edward Liveing by Mr. W. W. Ouless, and, by the ame artist, No. 231, a portrait of Sir Henry Morris in his robes as President of the Royal College of Surgeons of England, both of which are excellent. Of other striking portraits we may mention No. 18, Miss Sylvia Myers, by Mr. J. J. Shannon; No. 66, Professor H. A. Strong, by Mr. G. H. Neale; No. 195, Mrs. Hayes Sadler, by Mr. Charles Sims; and Nos. 406 and 678, portraits of children, by Mr. R. Peacock. Mr. George Henry is represented by at least two extremely clever portraits, No. 427, "The Nightingale," and No. 443, "Lady Margaret Sackville," which is next door to another striking portrait, No. 444, "The Red Cloak," by Mr. S. Melton Fisher. Still another admirable portrait is No. 743, by Mr. Harrington Mann, entitled "The Blue Jacket." Other pictures well worthy of note are No. 36, Mr. Stanhope Forbes's "Vegetable Shop"; No. 42, "Tristesse," by Monsieur Jean Paul Laurens, an honorary foreign academician; No. 83, "Fugitive," by Mr. Briton Riviere; and two pictures by academicians lately deceased, one being No. 101, a portrait of Mr. E. A. Abbey, by the late Sir William Orchardson, and the other, No. 127, entitled "The Cold North," by Mr. J. M. Swan, the latter being a picture of polar bears painted as none but he could paint them, for he was always successful in rendering the curious resemblance which the head of a polar bear has to that of a ferret. No. 174, by Mr. A. E. Borthwick, a picture entitled "The Presence," is one of the few pictures in the exhibition showing high imaginative quality. Passing on to other pictures, we may mention No. 266, by Mr. Chevallier Tayler, entitled "The Children's Hour"; No. 293, "Sunset," by Sir E. A. Waterlow; No. 368, by Mr. T. C. Dugdale, entitled "A Caller, Candle-light, and Tea"; No. 360, "Boys," by Mrs. Laura Knight, a clever study of boys bathing, full of light and air, which we are glad to see has been purchased by the Chantrey Fund; and No. 362, by Mr. Hugh G. Riviere, a portrait of Mr. Frank Benson wearing his O.U.A.C. coat, a good portrait, but defective in the painting of the legs, for Mr. Benson's left leg looks as if he had suffered from infantile paralysis. No. 484, by Mr. William Strang, is called a "Portrait Group." It is magnificently painted, exceedingly clever, and as ugly as it is clever. Mr. J. W. North sends one of his delightful landscapes in No. 522; and we have left to the last what are possibly the most interesting pictures in the exhibition—viz., Mr. Sargent's four impressionist sketches, Nos. 107, 136, 529, and 619. The first of these is entitled "Glacier Streams," while the other three deal with scenes in Albania and Corfu. They give the light and colour and general sense of atmosphere which were so marked in his sketches of Venice exhibited some years ago at the Carfax Gallery. Mr. Sims, besides his portrait mentioned above, has two of his rainbow and water phantasies in Nos. 543 and 903.

THE GOSPEL OF CLEANLINESS.—In his annual report to the Aberystwyth rural council Mr. J. James concludes as follows: Were I to preach in this land of preachers and sermons my text would be "Cleanliness is next to Godliness," and I would accordingly divide my discourse into three heads—firstly, cleanliness; secondly, cleanliness; thirdly and lastly, cleanliness. I would dilate upon the necessity of having clean air to breathe, clean nourishing food to eat, and clean water to drink; a clean house to live in, with clean surroundings. I would also emphasise the virtues of personal cleanliness and would condemn the mere ablution of hands and face as hypocrisy, humbug, and fraud. I would end my sermon by impressing on the minds of my audience the truth that a damp dwelling-house is a safe way to sanitary perdition.

SANITATION IN INDIA.

I.

THE courtesy of the various authorities connected with the sanitary aspect of India has once more enabled us to review the administration concerning sanitation in our great Eastern dependency. We shall accordingly notice first the matters relating to sanitary administration generally, as disclosed in the reports furnished to us; next, the administration of the hospitals and dispensaries; and thirdly, the reports in regard to the jails and asylums and vaccination.

THE SANITARY REPORTS.

The reports received embrace those for the sanitary administration of the North-West Frontier Province (Lieutenant-Colonel G. W. P. Dennys, I.M.S.), the Punjab (Major E. Wilkinson, I.M.S.), Bengal (Lieutenant-Colonel F. C. Clarkson, I.M.S.), the Province of Eastern Bengal and Assam (Lieutenant-Colonel E. C. Hare, I.M.S.), Burma (Major C. E. Williams, I.M.S.), and the Central Province and Berar (Colonel P. A. Weir, I.M.S.), the name of the sanitary commissioner following that of the province in each instance.

Comparative Vital Statistics.

The comparative vital statistics of the various provinces of India for the years 1908 and 1907 are as follows, stated in ratios per 1000:—

	Birth-rate.		Death-rate.	
	1908.	1907.	1908.	1907.
Eastern Bengal and Assam	41·14	37·01	30·74	29·30
Bengal	36·09	37·70	38·56	37·72
Central Provinces	52·84	52·46	38·12	41·70
Burma	34·84	32·82	28·23	26·60
North-West Frontier Province	37·30	32·52	35·83	35·12
Punjab	41·80	40·80	50·70	62·10

Contrasted with the years 1902–06 the ratios are as follows:—

	Birth-rate.		Death-rate.	
	1902–06.	1908.	1902–06.	1908.
Eastern Bengal and Assam	39·31	41·14	30·74	32·19
Bengal	39·08	36·09	34·63	38·56
Central Provinces	50·47	52·84	35·21	38·12
Burma	32·90	34·84	23·04	28·23
North-West Frontier Province	36·30	37·30	29·60	35·83
Punjab	43·30	41·80	45·30	50·70

Malaria.

Coming now to some of the chief diseases affecting the health of the above provinces we will first notice malaria, which accounts generally for the highest state of sickness.

In Eastern Bengal and Assam the ratio for fevers for 1908 was 22·37 per 1000, an increase of 1·20 over that of 1907, but lower than the decennial rate of 22·97 per 1000. Captain Ritchie, I.M.S., the civil surgeon of Jalpaiguri, drew up a scheme of operations against the disease. This comprised (*a*) quinine distribution by the free issue of quinine from July to December; (*b*) protection against mosquitoes by screening with wire gauze; and (*c*) the destruction of larval mosquitoes. The last measure consisted of (1) cleaning and levelling drains, jungle cutting, and filling up pits; and (2) spraying the mosquito breeding grounds with kerosene oil. Unfortunately, owing to the transfer of Captain Ritchie to another station, the work was interrupted during the four most important months, but 94,000 grains of quinine were distributed, and the other measures indicated above were carried out. The endemic index, which was formerly shown by Dr. C. A. Bentley to be 45 per cent. amongst children, was found to be 29 per cent. under 10 years of age by a "spleen census" taken at the end of March. There is no record, however, showing at what time of year Dr. Bentley's index was taken, whilst the percentage of enlarged spleens found at the end of the rainy season would certainly be higher than that in March.

With regard to blackwater fever the report of the Government Commissioner is now expected daily; it has been made clear that there is a close relationship between blackwater fever and exposure to intense malarial infection, and that an almost certain immunity can be obtained from the regular use of quinine combined with mosquito protection.

In Bengal the fever ratio was 23·44, compared with 23·18 in 1907, and 22·21 for the years 1903–07. The anti-malarial measures carried out consisted of the filling up of hollows and depressions, clearing jungles, treating foul tanks and collections of water with crude petroleum, and drainage work. The natives greatly appreciate these efforts. Measures have been taken to cheapen the price of quinine and to issue it not only in the form of powder but also in small tablets.

In the Central Provinces and Berar the deaths from fevers were 213,908, as compared with 217,773 in 1907, but the Sanitary Commissioner reports that the presumption is that the increased mortality attributed to fevers cannot be laid entirely to malaria, owing to lung diseases, such as tuberculosis, having been included, or acute dysentery and diarrhœa. Great attention has been paid to drainage and filling up of borrow pits and other depressions. The breeding places of mosquitoes have been treated with kerosene oil; about 72,300 cubic feet of pools and hollows were filled in during the year. Packets of quinine were also sold to the public.

In Lower Burma the fever death-rate was over 10 per 1000; in Upper Burma it was 8·85. Excellent work was done by Captain J. Good, I.M.S., by his well thought out system of drainage and extermination of the anopheles mosquito. In other parts of the province quinine was sold at cost price in the form of tablets, which are found to be more appreciated than powders. Proposals have also been made by the Sanitary Commissioner for the enactment of facilities for selling quinine at a cheaper rate.

The North-West Frontier Province showed a considerably smaller registration of deaths from fevers; the ratio was 26·62 per 1000, that for 1907 being 27·42.

In the Punjab fevers were by far the most important cause of the very high mortality recorded during 1908, furnishing a death-rate of 34·66 per 1000 out of the death-rate from all causes of 50·73, thus causing more than two-thirds of the total mortality of the province. Two-thirds of this great mortality occurred during the last four months of the year. The fever death-rate in 1907 was 20·16, and in the quinquennium 20·6, so that the mortality in 1908 was excessively high. The rate has, in fact, been only twice exceeded—namely, 38·05 in 1890 and 34·83 in 1892. In all these years the monsoon rainfall was very heavy, causing extensive floods, and in all the floods were followed by severe outbreaks of malaria. Breeding places were thus formed for mosquitoes. The malarial outbreak caused a very high mortality amongst children, the mortality being rather more than half the total fever mortality of the whole population under 10 years. Preventive measures for the destruction of the mosquito were undertaken, accompanied by the distribution of quinine either free or at cost price. The heavy and frequent floods rendered the destruction of the mosquito breeding places impracticable.

Plague.

Let us now return to plague, that disease which has effected such serious havoc in India of recent years. In Eastern Bengal and Assam Lieutenant-Colonel Hare luckily has no cases to report for 1908. The Plague Investigation Commission has been invited to extend its researches into this province to ascertain the causes which give this part of India immunity from the disease, an invitation which should result in benefit to the other parts of the country where the disease is rife.

In Bengal, again, we note with satisfaction that the mortality from this disease was the lowest since the year 1901, only 15,948 persons falling victims in 1908, against 83,602 deaths in 1907. 13 districts were free from the disease, whilst more than two-thirds of the deaths occurred in the Patna division. The climax of the epidemic occurred as usual in March, and Calcutta returned the highest death-rate. With respect to the measures for prevention, evacuation of the infected dwellings was the most popular, and this was effected often without any prompting, while chemical disinfection was carried out only in a few special cases at the instance of people themselves. Itinerant medical subordinates were employed in certain districts for the treatment of the cases and for supervising preventive measures. Rat destruction was carried out in almost all the districts of Behar, but the system of payments of rewards for dead rats is being gradually discontinued, the work being done by organised staffs. To catch these vermin traps were chiefly used, the people objecting to the use of poison. Major Gwyther, I.M.S., with respect to rat killing, holds that this made no appreciable difference in the numbers of these animals, as he thinks that in consequence of the scarcity and high prices of food-stuffs prevailing in his district there was less waste after meals, less thrown away, less food for rats, and therefore a less close connexion of the rats with human habitations.

With regard to inoculation as a preventive measure, this was still viewed by the people with great distrust. During the year 2710 inoculations, as contrasted with 2766 and 1777 in the two preceding years, were performed in the districts, whilst in Calcutta there were 3043 cases against 3123 and 101 in 1907 and 1906. Twelve cases of plague with four deaths at Bhagalpur, two cases at Monghyr, and one case at Muzaffarpur (in both instances with no deaths) are reported amongst the inoculated. It is to be earnestly hoped that the present attitude of the people with regard to this valuable measure of protection will be altered for the better. Lastly, plague pamphlets were freely distributed.

In the Central Provinces and Berar the total number of deaths from the disease was 6236. The preventive measures adopted to meet the epidemic were rat destruction, evacuation, and inoculation. Rat destruction was not universal owing to religious prejudices, evacuation was freely resorted to, whilst inoculation was unequally accepted, 19,323 persons receiving the prophylactic. The Sanitary Commissioner considers that the check to the disease by this measure proved satisfactory.

In Burma the total number of deaths from plague was 6752, against 9429 and 8637 in 1907 and 1906 respectively. This considerable reduction in the mortality was shared by all the division. In Lower Burma certain districts escaped plague infection as in previous years, owing to their isolation from infected regions. With regard to the preventive measures employed, with the exception of the Irrawady district, where the earth-oiling of the dwellings was adopted, reliance was placed on cleaning and improving the sanitary conditions generally of infected and threatened areas. In many cases the work was performed in too perfunctory a manner, but where it was thoroughly carried out, as in Rangoon, there has been a marked decrease in the prevalence of the disease. Rat destruction has also been carried out since 1906, and experience shows that where the rat population has suffered severely from the disease, almost to extinction, in any large plague-infected area, that locality has remained free from human plague for the whole of the succeeding plague season. Evacuation proved to be the most effective measure for the suppression of outbreaks. Earth-oiling in the Irrawady division postponed the onset of the epidemic at Henzada, but the mortality for the year as a whole was not greatly reduced by this method. The Sanitary Commissioner well points out that the real source of the predisposition to the disease lies in the insanitary conditions amongst which the poorer classes live, which foster the prevalence of rats, insects, and vermin. Anti-plague inoculation was employed generally, but was nowhere popular, and only was received willingly where there was any great mortality from the disease. Experiments are also being conducted with the Danysz virus, and a certain degree of success is recorded.

Coming now to the North-West Frontier Province, we find there were only 563 deaths recorded from plague, against 1547 in the previous year, only the two districts of Peshawar and Dera Ismail Khan having been visited by the disease.

Finally, regarding the Punjab, a most satisfactory state of affairs has existed with regard to this affection in 1908. This year has been by far the mildest as regards plague that has been experienced in the Punjab since the disease became widespread. To show the great loss which the province has sustained from this cause it will suffice to say that since its first invasion up to the end of 1908 no less than 2,061,885 deaths have resulted from it. In 1908, only 40,106 deaths were reported. The satisfactory nature of the decrease in the numbers is at once evident, when we remember that the Punjab furnishes some of the most valuable soldiers to our Indian army. The chief cause of this decrease in the mortality, according to the Lieutenant-Governor, cannot be attributed to inoculation, nor to the destruction of rats, nor to the absence of rainfall in 1907, but to the fact that the disease is probably working itself out. At length it would seem that this scourge is gradually being removed from the land. The Sanitary Commissioner,

however, would lay some influence to the less incidence of humidity, and he certainly produces strong arguments in his favour. Unfortunately, the natives still show little evidence of actual interest or desire to help themselves in the matter.

The measures undertaken for prevention have been rat destruction, which has had a considerable mitigating influence; evacuation, which has, however, been extremely unpopular in this province; and inoculation, 52,629 operations having been performed. The latter measure is not, however, accepted unless the disease is near and danger imminent, although its good effects are fully recognised. One excellent feature of the work in 1908 has been a large extension of general medical relief afforded by the plague medical staff, specially designed panniers containing drugs and instruments having been supplied to it; thus valuable help was given during the cholera and malarial outbreaks. Two special investigations also were carried out as to the effect of rat destruction and as to the recrudescence of the disease.

Cholera.

Let us now review the incidence of cholera as shown in the above reports.

In the Province of Eastern Bengal and Assam the provincial death-rate, 1·99 per 1000, was less than usual, but several of the Assam districts suffered severely owing to the repeated importation of fresh centres of infection during January and June. The cholera reports from the steamers during this period show that among the tea-garden labourers no less than 766 cases occurred on 116 vessels. The special arrangements made last cold weather to deal with the immigrant traffic, however, seem to have been attended with some success.

In Bengal the mortality in 1908 was unfortunately, in contrast with the foregoing, the highest ever recorded, amounting to 5·32 per 1000. The climatic condition of the year affected both the sufficiency of the drinking water and the food-supply. Only six thanas were free from the affection. This large mortality arose owing to the famine, with a large rise in the prices of food grains, causing the use of highly injurious foodstuffs by the poorer classes, and especially owing to the villagers drinking water from foul tanks during scarcity of water. But amidst this large increase we are glad to see that the most satisfactory results were due to the excellent precautions generally taken at all the important fairs and religious festivals held during the year. Additional sweepers were provided, all the wells were disinfected, and doolies were kept ready at several places for the removal of the sick and the dead. Great attention was paid to the sanitary arrangements in the various lodging-houses. In this way excellent results were attained. For instance, at the Sonpur fair, the biggest in the province, attended by 400,000 people, only three cases of cholera occurred. Again at Sonpur with 30,000 people attending only two stray cases occurred.

In the Central Provinces and Berar there were 9048 deaths as against 4291 in 1907, or 0·76 and 0·36 per 1000 respectively. The disease was only at all serious in two districts, and in particular the town of Chindwara was successfully protected from a threatened epidemic. Fortunately, the objections to the use of permanganate of potash in wells seem now to have disappeared. This measure, together with the issue of medicines with the aid of the vaccination staff, formed the chief means of meeting the epidemic.

In Burma the disease showed a tendency to increase, in spite of the greater attention devoted to sanitation; there were 11,911 cases as against 8378 in 1907. There was unfortunately some difficulty in getting the people to attend to the sanitary condition of their wells. Such wells are not provided with a cover and no well is set apart for the washing of clothes. The parapets frequently are in a ruinous state, whilst the masonry lining is not applied to any considerable distance below the surface of the ground. The measures adopted by the energetic Sanitary Commissioner, such as the use of permanganate for wells, closing of suspected wells, advising the people to use only cooked food and boiled water, and sanitary precautions for the excreta, were found of little avail amongst an ignorant and panic-stricken population. Voluntary and spontaneous evacuation of an infected village gave the best results.

In the North-West Frontier Province cholera was worse in 1908 than in any year since the inauguration of the province. The first case was in Peshawar in a pilgrim from Hardwar, who had been attending on a friend with the disease. From this origin it spread to other parts of the province. The civil surgeons of the districts affected all agreed that the agency of flies was the chief cause of the spread, and that water was only implicated to a small extent. There was a terrible epidemic of flies at Peshawar when the disease first broke out. Pamphlets were wisely distributed by the civil surgeons of Peshawar and Bannu concerning its prevention and treatment.

Lastly, in the Punjab after four years of but slight prevalence cholera broke out in epidemic form in 1908, causing a death-rate of 0·61 per 1000 and accounting for 12,297 deaths. The outbreak was primarily traceable to the fairs held at Kabás and Jawálámuki. A further outbreak was traced to a pilgrim returning from Hardwar. The Naina Devi Fair was responsible for another severe outbreak, thus once more showing the inherent dangers of these gatherings of the people. Kabás was responsible for 6000 deaths. The Sanitary Commissioner narrates an interesting case in which there is strong presumption that the incubation period of the attack in question was between three and four days.

These interesting reports are evidence of the unremitting labours for which the Government of India is indebted to its Sanitary Commissioners. It may not be invidious, perhaps, to mention especially the name of Major Williams, I.M.S., on whom the mantle of Colonel W. G. King, I.M.S., the late Sanitary Commissioner of Burma, has not unfitly descended.

(To be continued.)

THE EARLY TREATMENT OF THE INSANE IN THE COUNTY OF LONDON.

THE Asylums Committee submitted to the London County Council on May 3rd the draft of a Bill embodying the decision of the Council to seek powers to establish and maintain a receiving house for the early treatment of persons alleged to be insane.[1] The committee stated that the Bill followed the lines of previous Lunacy Acts Amendment Bills promoted by the Council, but two variations had been decided upon since the question was last considered. The first variation provided for the appointment by the Asylums Committee of medical men who should act as certifying practitioners. The principle of the establishment of receiving-houses, which the committee had advocated for many years, was endorsed in the report of the Royal Commission on the Care and Control of the Feeble-minded. Amongst the recommendations of the Commission was one for the appointment of certifying medical practitioners (Recommendation 36) who should take the place of the ordinary medical practitioner now called in by the justice of the peace to certify the insane. In the County of London, in consequence of the majority of alleged lunatics being brought into the workhouses, a practice had grown up in most parishes and unions by which the infirmary or workhouse medical officer was called upon by the justice of the peace to certify as to the condition of the alleged lunatic, and usually a fee was paid to the medical officer for each certificate he gave. The Royal Commission having come to the conclusion that there should be properly appointed certifying practitioners, the committee had thought it desirable to introduce this provision into the Bill. It was also proposed to make it compulsory that every alleged lunatic should go in the first place to the receiving house. In former Bills it was made optional for the justice of the peace to order a lunatic to be sent to the receiving house or to the asylum, as he thought fit. It was proposed by Clause 6 of the Bill that in every case the certifying justice, if he thought that the person brought before him ought to be detained, should, instead of proceeding in the manner provided by the Lunacy Acts, 1890–8, direct such person to be received and detained in the receiving house.

The Asylums Committee next dealt with the decision of the

[1] See THE LANCET, July 24th, p. 249, and Oct. 16th, 1909, p. 1161.

Council, on the advice of the Finance Committee,[2] to seek powers for the establishment of one instead of two receiving houses as originally recommended. The committee urged the Council to give this point further consideration. In the report submitted last July the committee expressed the opinion that two receiving houses, one on the north and one on the south side of the Thames, each to accommodate 250 patients, would be sufficient for the needs of London, and that the total cost should not exceed £150,000 to £180,000. This suggestion was put forward as the result of long experience of the numbers and classes of patients received at the asylums and of some knowledge of the conditions under which alleged lunatics were dealt with at present in the London workhouses and Poor-law infirmaries. The proposal to establish receiving houses should not be regarded as altogether tentative, especially in view of the recommendations of the Royal Commission on the Feeble-minded. The only question was as to the total accommodation required. One receiving house could not cope with the whole of the 7000 or 8000 cases of alleged lunacy dealt with annually in London—some 150 cases a week. It would be necessary, therefore, to schedule a district more or less extensive which a receiving house was to serve. In the area where the Receiving House Act operated there would be a vital alteration in the method of dealing with alleged lunacy; for instance, it would be unlawful for an alleged lunatic to be received in a workhouse (except under the conditions set out in Clause 21 of the Bill) and the method of certification would be new. No doubt the Council would wish to provide, in due course, sufficient accommodation to allow of the whole county having the advantage of the receiving house system and its attendant benefits; otherwise there would exist the anomaly of one law operating in one part of the county and another in the remainder. The committee thought, therefore, that the Council should not limit its application for powers to one receiving house, but should put itself in a position to provide whatever accommodation might be found necessary. The advantage of the receiving house principle had been recognised so long, and the urgent need for giving practical effect to it had been so strongly emphasised by the Royal Commission that the committee believed the Council, on further consideration, would agree there was no need to treat the proposal to apply for powers as though the application were directed to some end entirely experimental, leading in a direction altogether unknown. The committee asked the Council to rescind the resolution of Oct. 12th, 1909, limiting the application to one receiving house, and to resolve instead:

> That application be made to Parliament in the session of 1910 for powers to enable the Council to establish and maintain receiving houses for alleged lunatics in the County of London.

The Finance Committee, reporting on the proposal, recapitulated its reasons for opposing the larger scheme (reported in THE LANCET of July 24th, 1909), and pointed out further that the Asylums Committee had introduced new matter, particularly the proposal making it compulsory that every alleged lunatic should go in the first place to a receiving house. The Finance Committee was still without information which would enable it to advise the Council as to the financial effect of the present proposals. It certainly was not present to its mind at the time of the earlier report that an essential part of the scheme was that every person alleged to be a lunatic should pass through the receiving house, and such a scheme formed no part of previous Lunacy Bills. If the Bill was approved in the form desired by the Asylums Committee the Council would be definitely committed to a new policy as regards the early treatment and certification of lunatics, and, however desirable the changes might be, they would involve considerable expenditure, on both capital and maintenance accounts, of unknown amount. In the opinion of the Finance Committee the Council would be ill-advised to agree to the present proposal of the Asylums Committee, or to any extension of its previous decision until it was in possession of full information as to cost. On general and financial grounds the Finance Committee opposed the recommendation.

The report was not reached until 1.30 A.M., when the Council had been sitting for 13 hours, so the consideration of the matter was adjourned.

[2] THE LANCET, vol. ii., 1909, p. 1161.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.

A COUNCIL meeting of this association was held at 34, Copthall-avenue, E.C., on April 28th.

The chief business before the meeting was the annual meeting of the association at Halifax. Dr. MAJOR GREENWOOD, the honorary secretary, said that Dr. A. Drury had arranged for this to take place on June 29th. The Mayor of Halifax would open the conference at the Town-hall, and later the Mayor and Mayoress would entertain the members at afternoon tea. The Mayor and Mayoress had also accepted the invitation of the association to the annual dinner in the evening.

Dr. DRURY said he had that week called a meeting of the medical officers of the Halifax Union, who had pledged themselves to give all the assistance in their power to promote the success of the conference, and he could assure the council that no effort would be spared to make the gathering at Halifax a thorough success.

The council decided that invitations should be sent to all members of the Poor-law Medical Service in England and Wales.

The HONORARY SECRETARY reported that the answers to the questions submitted to the outdoor Poor-law Medical Service had been analysed by himself and Mr. A. Withers Green, with the following results:—

1. Are you in favour of the abolition of boards of guardians throughout England and Wales?—To this question 37 per cent. of the answers were in the affirmative and 59 per cent. in the negative.

2. What authority would you propose to set up?—To this question 12 per cent. of the answers were in favour of an "*ad hoc* authority," 22 per cent. for the statutory committee of the county council, and only 3 per cent. in favour of the abolition of any special Poor-law authority. N.B.—Only the answers of those who wished for the abolition of the guardians were counted with regard to this question.

3. Should any difference be made between medical and other public relief beyond the disfranchisement in the case of the former?—77 per cent. of the answers were in the negative, 8 per cent. in the affirmative.

4. Should there be any "test," or "deterrent" such as the present medical order, to regulate the granting of medical relief to poor applicants? Or should the latter be permitted to claim public assistance subject to no other liability than having to pay the cost of the same, if proved to be in a position to?—83 per cent. were in favour of a test, 11 per cent. opposed to it.

5. Are you in favour of a public assistance medical scheme based on provident dispensaries, subsidised by the State, and contract practice generally?—83 per cent. of the answers were opposed to this and 12 per cent. in favour.

6. Are you in favour of a public medical service based on an amalgamation of the present Poor-law Medical Service with the sanitary medical service?—60 per cent. were opposed to this and 33 per cent. in favour.

7. Do you approve of the district medical officer being made relieving officer so far as medical relief is concerned?—76 per cent. opposed to it; 22 per cent. in favour.

8. Are you in favour of "whole-time" or "part-time" appointments in any reformed public assistance medical service?—17 per cent. were in favour of "whole-time" appointments; 71 per cent. were in favour of "part-time" appointments.

9. Are you in favour of a reform of the present Poor-law system, or would you prefer a "break-up"?—11 per cent. in favour of a "break-up"; 82 per cent. in favour of "reform."

10. Do you think that a "unified medical service," that attended to all poor applicants with no other test or deterrent than the liability to be compelled later to pay the cost, would, or would not, be dangerous to the interests of all general practitioners in poor districts?—Answers in the affirmative were 90 per cent.; in the negative, 6 per cent.

This analysis was approved by the council, and it was decided that resolutions framed on these answers should be submitted to the general meeting in Halifax in June, and, if carried there, should again be brought forward for confirmation at the meeting in London during the British Medical Association week in July–August next.

NURSING CONFERENCE AND EXHIBITION.

THE Third Annual Nursing and Midwifery Conference and Exhibition was held at the Horticultural Hall, Westminster, from April 27th to 30th.

The ceremony of opening the Conference was performed by H.R.H. Princess Christian, who was received by Lady Balfour of Burleigh, Sir Dyce Duckworth, and Dr. F. H. Champneys. Princess CHRISTIAN said she had taken a deep interest in nurses and their work for the past 40 years, and felt that every effort should be made to ensure nurses being the perfect help to the doctor which now they were expected to be.

Dr. CHAMPNEYS occupied the chair for the first day's session, which practically covered the midwifery topics.

Miss LUCY ROBINSON read a paper on the Living Wage for Midwives in Rural Districts, showing that if the fees obtained by midwives all through the country were equally divided among those who are notified as practising the earnings of each midwife would amount to £16 a year.

Dr. A. NIMMO WALKER, speaking on the Prevention of Infantile Blindness, described the methods adopted in Liverpool. On the notification of any inflammatory condition of the eyes of the newly born, a visitor is sent to take a swab of the discharge. If on examination this is found to contain bacteria the authorities of the Eye Hospital urge the immediate removal of the child *and its mother* to the hospital, where it can be under constant supervision and treatment without being deprived of its natural sustenance. An ambulance is sent for the patient, and it is stated that so far no evil has resulted from the early removal, though 200 cases have been treated in this manner in the last two years. The duration of their stay in hospital is from one to six weeks. In the last year the amount of blindness has been halved, though the number of cases admitted was double that of the previous year.

Mr. F. E. FREMANTLE, medical officer of health of the county of Hertfordshire, spoke in favour of the report of the Departmental Committee appointed to consider the working of the Midwives Act, of which he was a member. The findings and recommendations of that committee did not commend themselves to subsequent speakers, nor, to judge by comments, to the majority of the audience.

Miss ALICE GREGORY, who sits on the Midwives Committee of the London County Council, declared that while the interests of the Central Midwives Board, of the medical societies, the ratepayers, and, incidentally, of the midwives, had been considered, the mother had been left out as of little or no account. The Act had made it compulsory on midwives to recommend the attendance of a medical man, but in the tardy arrangements for the payment of such attendance it could only suggest pauperising the patients. It had forbidden unqualified women to attend labour for gain, and had provided no qualified persons to take their place in the scattered rural districts. It had hung a rope round the neck of the handy woman, but rather than pay for skilled attendance it left her, trusting to her human kindness, to go on attending *for nothing* rather than let her neighbour die; and if any harm came of it the authorities would probably treat her leniently. It had also declined to raise the standard of training, content to let England be behind every other European country in this. In the discussion which followed Dr. MARGARET MERRY SMITH, Dr. A. H. BYGOTT, and others took part.

Mrs. LAWSON, President of the National Association of Midwives, Manchester, then read a paper urging reform in the constitution of the Central Midwives Board and direct representation of midwives. Mrs. STEPHEN GLANVILLE, speaking on the same subject, urged the professional rather than the personal element in all their movements towards progress; but while admitting that a higher standard of education was needed, she claimed that midwives, and especially those who belonged to a society such as the Midwives' Institute, had the interests of the mother and child as much at heart as the medical representatives on the Board. Dr. CHAMPNEYS, in closing the session, agreed with the last speaker in the necessity for putting aside personal and even society interests in the effort to carry out the main principle of the Act. To meet some of the difficulties in rural districts he suggested the endowment of a midwife, just as beds are endowed in hospitals.

Sir DYCE DUCKWORTH presided over the second day's session, when the subjects dealt with included Fever Nursing, by Dr. SIDNEY PHILLIPS, and the Duties of Probationers in Provincial Hospitals, by Dr. E. B. RECKITT. Discussing the danger of infection to attendants on fever cases, and the complications which sometimes ensue, Dr. Phillips gave it as his opinion that these conditions were intimately connected with crowding in the wards and consequent reduction of the quantity of fresh air obtainable.

Poor-law nursing in its various aspects and branches occupied Friday's afternoon session, Miss BRODIE-HALL presiding. Papers were contributed by Miss GIBSON, matron of the Birmingham Infirmary; Miss WILSON, whose paper was read for her; and Miss DOUGLAS TOWNSEND. The general feeling of the meeting at the conclusion appeared to be that while small infirmaries could not supply the variety of cases and experience necessary to train nurses efficiently, the work and equipment of the large institutions under the Poor-law were in every way equal to those of large general hospitals. Under these circumstances the tiresome and invidious distinction between hospital and Poor-law nurses ought to die out; and it was hoped that in any future scheme for the registration of nurses the same certificate would be available for both.

In the evening Miss E. L. EDEN gave a lantern lecture on the History of Nursing, exhibiting a unique collection of photographic slides representing nursing in all ages. The earliest of these, dating from ancient Egyptian times and copied from the walls of the Pyramids, showed the attendance on women in childbirth. An interesting photograph, taken from the Vase of Sosias in the Berlin Museum, represented Achilles bandaging the arm of his friend Patroclus, and using a double-headed bandage. Coming down to the Middle Ages, the pictures gave a glimpse of the wards of the Hôtel Dieu de Paris, which was nursed by the Augustinian nuns for 500 years. Here there were beds containing two and even more patients, while another slide showed the nuns at work washing the hospital linen in the river. Among a number of excellent photographs was one of a plague attendant's costume of the seventeenth century, with the curious beak-like projection over the nose through which the air was inspired over a disinfecting material. The last pictures showed the development of modern nursing in the up-to-date equipment of a ward in St. Bartholomew's Hospital, an operating theatre, and a district nurse belonging to the Queen Victoria's Imperial Institute entering a cottage on the west coast of Ireland.

Saturday's conference dealt with a variety of subjects, including massage, maternity clubs and crèches, Territorial nursing, and State registration. In the afternoon Dr. MURRAY LESLIE occupied the chair, and the principal speakers were Miss ANNIE MANLEY, a founder of the Incorporated Society of Trained Masseuses, Miss KLAASSEN, and Miss BARTON, matron of the Chelsea Infirmary. Among the speakers in the evening, when Mr. JOHN LANGTON presided, were the Hon. SYDNEY HOLLAND, Sir VICTOR HORSLEY, Dr. and Mrs. BEDFORD FENWICK, and Miss HAUGHTON, matron of Guy's Hospital. The subject discussed was the State Registration of Nurses, and it was warmly debated. It was a rule of the conference that no resolutions were to be put.

The exhibits displayed on the stalls of many of the leading firms of instrument makers included the latest developments of scientific surgery for the use of medical man, nurse, or patient. A mask and face-protector on Messrs. Garrould's stand attracted considerable attention, and various improved bed-tables and rests were to be seen. A new "home Pasteuriser" was exhibited by Messrs. Townson and Mercer. Every variety of milk food and prepared milk had its place.

Attention was drawn at one of the sessions of the Conference to a small stall at which might be seen models of female urinettes recommended for use in women's free

lavatories. These models, made at the suggestion of Dr. R. Murray Leslie by Messrs. Adamsez, obviate the danger of infection by their shape and the absence of any woodwork.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

THE annual general meeting of the London and Counties Medical Protection Society was held at 31, Craven-street, Strand, London, on April 27th, Dr. G. A. HERON being in the chair.

The annual report of the council adopted by the meeting gave an interesting account of the strong financial position of the society, and stated that there had been a steady increase in the membership during the past year. The following resolution of the midwives committee of the society was approved by the council:—

That having regard to the proposed payment by boards of guardians of the doctors called in to assist midwives, the London and Counties Medical Protection Society recommends the medical men in each union to meet and confer on the subject, and to agree as to what fee, or fees, they will accept, and then combine to insist on such fee or fees being paid (or guaranteed) by the guardians, and paid on the statement of the medical man that he is unable to obtain payment of his fee from the patient or her representatives.

The CHAIRMAN in the course of his remarks referred to this resolution and declared that the matter was one of importance not only because it dealt with a branch of work which was of the very first consequence to the general practitioner of medicine, but because he thought that a fight properly carried out by the medical profession with the local authorities who were to work the Act would be, if it were prudently conducted, productive of much good to the profession. If they looked at what had taken place about the Midwives Act they would see that it followed exactly the lines of every other work which was offered to the medical profession by local authorities. When it came to a question of fees, the local authority settled the fee. The medical profession was not asked whether it would work for those fees, but it was practically put in this way: "There is your fee, take it or leave it." He could not but think that that should not be permitted to go on. He thought that the medical profession, following the recommendation of their council, in every locality in the country when its local authority was considering the payment which it would make for midwifery, should meet and agree that they would receive certain fees and only those fees, and when the local authority said "There is our scale of fees, those of you who like it can take it," the answer should be: "We have nothing to do with your scale of fees; that scale may suit you but it does not please us. Our position is, we are not going to work for the fees which you dictate, but for fees which we ourselves settle." The local medical men should say that unless the authorities accepted their terms they would have to look to others for having the work done. That was the only way in which the medical profession would ever make itself of the faintest importance to local authorities where fees were concerned. If they did not unite and insist upon their rights, as lawyers and others had done, medical men were undeserving of any consideration at all. He thought the day had gone by when that sort of thing should be treated in a sentimental manner, and if anyone said he was advocating trades union methods he had no objection to accept that position and to say it was the duty of a man, which he owed to his wife and children and those dependent upon him, that he should insist upon being adequately paid for what he did, while he should be the judge of what adequate payment was. He was at all events entitled to be heard.

UNIVERSITY OF LONDON: KING'S COLLEGE.—A short course of special lectures in physiology, the subject being the Relationship of the Brain to Voice, will be delivered by Dr. F. W. Mott in the Physiological Laboratory of King's College on Monday afternoons, May 23rd, 30th, and June 6th, at 4.30. These lectures are free to all members of King's College, all students in medical schools, all internal students of the University of London, and to medical men on presentation of their cards.

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

The County of Berkshire.—For the purpose of the medical inspection of school children the county has been divided into two parts: one includes the Bradfield rural district and the district eastwards of it, the other all the administrative country westward of Bradfield rural district. The school medical officer is Dr. Gerard C. Taylor, the county medical officer of health, who for inspectorial purposes has the assistance of two medical officers. The school population here in question does not, of course, include the boroughs of Windsor, Maidenhead, and Newbury, but the number of children on the rolls amounts to about 24,480. Dr. Taylor condemns what appears to be the usual method of dry sweeping in the schools, and he urges that damp sawdust should be scattered over the floors prior to cleansing. Much of the dust in schoolrooms is, he thinks, caused by the bad surface of the playgrounds, and he would evidently like to see more asphalting carried out. In 51 of the schools there is no supply of drinking water on the premises. As regards excrement disposal, Dr. Taylor is in favour of pail closets, to the contents of which earth is freely added. Pediculi were present in the hair of 16·5 per cent. of the children examined, a proportion which shows a decrease of nearly 6 per cent. upon the figures for last year. 57 per cent. of the children had defective teeth, and it is found to be extremely rare that any attempt at treatment has been made. Enlarged tonsils were found in 27 per cent. and adenoids in 17 per cent. It is not stated what means were adopted for ascertaining the presence of adenoids. Of the 2856 whose sight was tested, 73 per cent. had normal vision of both eyes. 4 per cent. had defective hearing, but this percentage is open to revision. 88 instances of enlarged thyroid were recorded, 22 amongst boys and 66 amongst girls, principally at the age of puberty. The available methods of treatment are thus grouped: (*a*) payment of doctors' or specialists' fees; (*b*) subscription to a provident dispensary or medical club; (*c*) a relieving officer's order; and (*d*) a recommendation for a voluntary hospital. As regards (*a*), it is pointed out that, although many of the parents are both able and willing to pay for medical attention for an acute and short illness, they are less able to do so for an operation or prolonged treatment; while with respect to (*b*) Dr. Taylor thinks that the rates of subscriptions to provident clubs do not allow of much time being devoted to individual patients. Besides, the rules but rarely include operative interference, vision-testing, or dentistry. (*c*) As to the employment of the district medical officer, Dr. Taylor observes that, although the only recognised qualification for gratuitous treatment is "destitution," it is customary in some unions to grant medical relief on loan, the case being subsequently considered by the guardians when either the loan is written off or repayment obtained. It seems that in Berkshire school medical inspection has in certain districts increased the number of applicants for medical relief, and it is regarded as unfair that the work of district medical officers should be thus augmented without a proportional increase in pay. The Poor-law Order of 1847 enables the guardians with the consent of the central authority to pay compensation for extra services, and possibly where the demand upon the time of the district medical officer has been increased some remuneration might be obtained under this provision. But, as Dr. Taylor foresees, this point raises some important general issues as to the extent to which the Poor-law authorities are prepared to extend facilities for treatment, and as to whether public opinion will permit parents to be compelled to apply for Poor-law medical relief when not otherwise in need of public assistance. With reference to (*d*)—i.e., a recommendation for a general hospital—it appears that considerable use is already made of the Royal Berkshire Hospital at Reading, the Radcliffe Infirmary at Oxford, and the King Edward VII. Hospital at Windsor, while a few of the children are brought up to the special or general hospitals in London. There are also several cottage and other hospitals in the county which are available for operations. Dr. Taylor thinks that proposals to subsidise voluntary hospitals out of the education rate are not likely to meet with general approval, since these hospitals already compete

seriously with private practice and the Poor-law medical service. There is, he adds, "a strong feeling, not confined to the medical profession, against conducting hospitals on *quasi*-charitable lines at the expense of the honorary staff and general practitioner."

The County of Essex.—There appears to have been considerable difficulty in arriving at a decision as to the best method for inspecting the school children in this administrative county, and with the delays which were occasioned no systematic inspection was undertaken before the end of January, 1909, a fact which has to be remembered in drawing any inferences from the statistics. One of the proposals was to place certain areas under the charge of local medical officers of health, while another was a further division of the county and the carrying out of inspection by local medical practitioners. Finally, Dr. J. C. Thresh, who is the school medical officer, advised the appointment of three whole-time inspectors, and this subsequently resulted in two being appointed at £250 a year each. But it soon became clear that the two inspectors could not cope with the work and a number of temporary inspectors were appointed, the services of one of these being permanently retained at the end of 1909, there thus being now three inspectors as originally advised. But Dr. Thresh thinks that a fourth inspector will soon be necessary. No school nurse has yet been appointed. Throughout the county it was found that the girls were better clothed and booted than the boys, about 3¼ per cent. of the former and and 5 per cent. of the latter being insufficiently clad or shod, or both. There are marked variations in the percentage of defects and vermin found in the different districts, and these differences are of a nature to suggest that the personal equation of the inspector may have been operative. In the table relative to cleanliness of body and head the boys at Grays showed 10 per cent. of dirty bodies, but only 3·3 per cent. of dirty heads, while amongst the girls the dirty heads in other districts were more numerous than at Grays. But the figures as regards Grays are throughout the whole inspection very remarkable, and special circumstances do seem to obtain there. Dr. Thresh asked another inspector to see the children, and he, too, pronounced that "many children are verminous from the top of their heads to the soles of their feet, their bodies smell horribly, ... and they are quite unfit to sit amongst the clean children," a condition which suggests the necessity of greater supervision by the teachers. In the matter of nutrition no less than 50·7 per cent. of the Grays boys and 40·3 per cent. of the girls were found with their nutrition below normal, these percentages in each sex being enormously above those of any other district. But another inspection showed general nutrition as distinctly bad in 26·4 per cent. of the boys and 25 per cent. of the girls, and Dr. Thresh is satisfied that in Grays and Tilbury 25 per cent. of the school children require special treatment and another 25 per cent. require more suitable food. So bad are the conditions regarded here that it is proposed to supply cod-liver oil and Parrish's food to the parents at cost price. Adenoids appear to be unduly prevalent in Essex, the children on admission showing the condition in 22·5 per cent. of the boys and 18·4 per cent. of the girls. But in this connexion it is suggestive to learn that at Grays one inspector found 20 per cent. of the children to require treatment for adenoids whereas another inspector, examining the same children, regarded 40 per cent. as requiring treatment. Dr. Thresh lays great stress upon operative treatment for adenoids, and he deplores the advice given by some practitioners in Essex to the effect that the children will gradually improve without treatment. He insists, too, that to be effective surgical treatment must be followed by breathing exercises through each nostril separately. As to the treatment of defective vision, it is of interest to hear that the county council has provided an ophthalmoscope and a box of refraction lenses, and that it is hoped that one of the inspectors will in future examine and personally prescribe glasses for selected children. Apparently, too, arrangements are being made to provide spectacles through local organisations. Some cardiac trouble was found in 1·5 per cent. of the boys and 1·1 per cent. of the girls; the amount of lung disease, exclusive of tuberculosis, was 1 per cent. in each sex. The number of children with pulmonary tuberculosis was too small to base a percentage upon. All the inspectors are unanimous as to the rarity of this disease amount school children. With respect generally to treatment, the various school managers have appointed one or more of their members to persuade and assist the parents to obtain the necessary advice, and Dr. Thresh reports that the results have been excellent. Arrangements are also being made to procure the use of an X-ray apparatus or to purchase a portable one. Dr. Thresh, who evidently thinks it wise to proceed cautiously at first, suggests that in future, when the local committees are fully aroused, the county might consider the advisability of contributing to hospitals, infirmaries, and dispensaries, and he hints at the possibility of a school clinic at Grays. There is much in Dr. Thresh's report which is worth serious consideration.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8388 births and 4249 deaths were registered during the week ending April 30th. The annual rate of mortality in these towns, which had been equal to 15·0 and 13·7 per 1000 in the two preceding weeks, further declined to 13·1 in the week under notice, and was lower than in any previous week of this year. During the first four weeks of the current quarter the annual death-rate in these towns averaged 14·2 per 1000, and in London during the same period the rate did not exceed 13·9 per 1000. The lowest recorded annual rates of mortality during last week in these 77 towns were 5·9 in Leyton, 6·1 in Bury, 6·9 in Hornsey, and 7·2 in Willesden and in Handsworth; the rates in the other towns ranged upwards, however, to 20·6 in Oldham, 20·7 in Wallasey, 21·0 in Merthyr Tydfil, and 21·8 in Burnley. In London the recorded death-rate last week did not exceed 13·0 per 1000. The 4249 deaths registered last week in the 77 towns showed a further decline of 218 from the numbers returned in the two preceding weeks, and included 364 which were referred to the principal epidemic diseases, against 383 and 345 in the two previous weeks; of these 364 deaths, 138 resulted from whooping-cough, 115 from measles, 40 from diphtheria, 37 from diarrhœa, 20 from scarlet fever, 13 from enteric fever, and 1 from small-pox. The mean annual rate of mortality in the 77 towns last week from these epidemic diseases was equal to 1·1 per 1000, and corresponded with the rates in the previous week. No death from any of these epidemic diseases was registered last week in Cardiff, Brighton, Tottenham, Wolverhampton, or in 13 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2·7 in Liverpool, 2·8 in Warrington, 3·1 in Devonport, 3·3 in East Ham, and 7·2 in Merthyr Tydfil. The fatal cases of whooping-cough in the 77 towns, which had been 143 in each of the two preceding weeks, declined to 138 last week; they caused annual death-rates, however, equal to 1·8 in Oldham, 2·0 in Gateshead, 2·1 in Warrington, and 2·5 in Devonport. The 115 deaths from measles showed an increase of 18 upon the number in the previous week; the highest death-rates from this disease last week were 1·6 in Swansea, 1·8 in Bradford, 2·7 in East Ham, and 6·6 in Merthyr Tydfil. The 40 deaths referred to diphtheria exceeded the numbers in recent weeks, and included 13 in London and its suburban districts, 3 in Bristol, 3 in Liverpool, and 3 in Leeds. The deaths attributed to diarrhœa, which had been 34 and 40 in the two previous weeks, declined again last week to 37. The 20 fatal cases of scarlet fever were fewer than in any previous week of this year; 4 occurred in Liverpool and 2 in St. Helens. The deaths referred to enteric fever, which had been but 15 and 9 in the two previous weeks, did not exceed 13 last week, of which 3 were returned in Manchester and Salford. The fatal case of small-pox occurred in Hull. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily declined in the 28 preceding weeks from 2819 to 1510, were 1509 on April 30th; 192 new cases of this disease were admitted to these hospitals during last week, against 197 and 196 in the two preceding weeks. No case of small-pox was under treatment in these hospitals on Saturday last. Of the 1217 deaths registered in London during the week under notice 224 were referred to pneumonia and other diseases of the respiratory system, showing a further decline of 33 from the numbers returned in recent weeks; these 244 deaths were 62 below the corrected average

number in the corresponding week of the five years 1905–09. The causes of 20, or 0·5 per cent., of the deaths registered in the 77 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during the week were duly certified in Manchester, Birmingham, Leeds, Sheffield, Bristol, West Ham, and in 58 other smaller towns; the 20 uncertified causes of death in the 77 towns included 3 in London and 2 each in Liverpool Blackburn, Preston, Sunderland, and Gateshead.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 998 births and 630 deaths were registered during the week ending April 30th. The annual rate of mortality in these towns, which had been equal to 18·5 and 16·3 per 1000 in the two preceding weeks, rose again to 17·4 in the week under notice. During the first four weeks of the current quarter the death-rate in these towns averaged 17·6 per 1000, and exceeded by 3·4 the mean rate during the same period in the 77 largest English towns. The annual death-rates last week in these eight Scotch towns ranged from 11·7 and 13·8 in Paisley and Leith to 22·0 in Greenock and 32·8 in Dundee. The 630 deaths from all causes in the eight towns during last week showed an increase of 40 on the number in the previous week, and included 76 which were referred to the principal epidemic diseases, against 123, 97, and 87 in the three preceding weeks. These 76 deaths were equal to an annual rate of 2·1 per 1000; the mean death-rate from the same diseases in the 77 English towns last week did not exceed 1·1 per 1000. These 76 deaths in the Scotch towns last week included 44 from measles, 16 from diarrhœa, 7 from whooping-cough, 5 from scarlet fever, 2 from diphtheria, and 2 from "fever," but not one from small-pox. The fatal cases of measles in the eight towns, which had been 74, 64, and 59 in the three preceding weeks, further declined last week to 44, of which 32 occurred in Dundee, 5 in Glasgow, and 3 both in Paisley and in Greenock. The 16 deaths attributed to diarrhœa corresponded with the number in the previous week and included 7 in Glasgow, 4 in Dundee, and 2 in Aberdeen. The 7 fatal cases of whooping cough, of which 5 occurred in Glasgow and 2 in Dundee, showed a slight increase. Three of the 5 deaths from scarlet fever, and both the deaths referred to "fever," were returned in Glasgow; the two deaths from "fever" were certified as due to cerebro-spinal meningitis. The deaths in the eight towns referred to diseases of the respiratory system, which had been 126 and 92 in the two preceding weeks, were 93 in the week under notice, and were 6 below the number in the corresponding week of last year. The causes of 10, or 1·6 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·5 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 703 births and 485 deaths were registered during the week ending April 30th. The mean annual rate of mortality in these towns, which had been equal to 23·2 and 22·4 per 1000 in the two preceding weeks, further declined to 22·0 in the week under notice. During the first four weeks of the current quarter the annual death-rate in these Irish towns averaged 22·7 per 1000, whereas the mean rate during the same period did not exceed 14·2 in the 77 largest English towns, and 17·6 in the eight principal Scotch towns. The annual death-rate during last week was equal to 23·9 in Dublin (against 13·0 in London), 23·1 in Belfast, 19·9 in Cork, 20·4 in Londonderry, 19·1 in Limerick, and 23·4 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish town districts was equal to 17·0 per 1000. The 485 deaths from all causes in the 22 town districts last week showed a further decline of 9 from the numbers in the two previous weeks, and included 39 which were referred to the principal epidemic diseases, against 39 and 41 in the two preceding weeks; these 39 deaths were equal to an annual rate of 1·8 per 1000; in the 77 English towns the mean rate last week from the same diseases did not exceed 1·1 per 1000, while in the eight Scotch towns it was equal to 2·1. The 39 deaths from these diseases in the Irish towns last week included 20 from measles, 12 from whooping-cough, 4 from diarrhœa, 2 from "fever," and 1 from diphtheria, but not one either from scarlet fever or from small-pox. The fatal cases of measles in the 22 towns, which had been 17 and 9 in the two previous weeks, rose to 20 last week, all of which occurred in Belfast. The deaths from whooping-cough, which had been 9 and 17 in the two preceding weeks, declined again to 12 last week; they included 4 both in Dublin and in Belfast, and 2 in Lisburn. Both the deaths from enteric fever occurred in Dublin, and the fatal case of diphtheria in Belfast. The 4 deaths attributed to diarrhœa were fewer by 2 than the number in the previous week. The deaths in the 22 towns referred to pneumonia and other diseases of the respiratory system, which had been 129, 121, and 118 in the three preceding weeks, further declined to 96 in the week under notice. The causes of 18, or 3·7 per cent., of the deaths registered in the Irish towns last week were not certified; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·5 per cent., and in the eight principal Scotch towns it was equal to 1·6 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff-Surgeons: R. St. G. S. Bond to the *Crescent*, temporary; R. S. Osborne to the *President*, additional, for Royal Naval College, Greenwich, temporary; A. W. B. Livesay to the *Cornwall;* E. T. P. Eames to the *Devonshire;* E. G. E. O'Leary to the *Doncgal*, and as Acting Interpreter in French; and M. H. Knapp to the *Natal*, on recommissioning. Surgeons: G. R. McCowen to the *Donegal;* and J. J. H. Rooney to the *Natal*, on recommissioning.

Lieutenant-Colonel Charles L. Josling retires on retired pay (dated May 4th, 1910).

The undermentioned Captains to be Majors (dated April 27th, 1910):—George J. S. Archer, Robert Selby, Sydney O. Hall, Alfred E. Weld, James S. Gallie, Francis J. C. Hefferman, Arthur E. Thorp, Henry Herrick, James Cowan, Austin R. O'Flaherty, Henry B. G. Walton, and Edmund P. Hewitt.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel W. Caton Jones, in charge of the Military Hospital at Colchester, has been posted to Tidworth. Lieutenant-Colonel P. C. H. Gordon, from Rangoon, has been appointed to Bulford Camp, Salisbury Plain. Lieutenant-Colonel H. J. Fletcher, from Sialkot, has been transferred to Rawal Pindi. Major M. M. Lowsley has been appointed a Specialist in Midwifery and Diseases of Women and Children to the Third (Lahore) Division. Major C. W. R. Healey has been appointed to command the Station Hospital at Nasirabad. Major A. J. Luther, from Burma, has been posted to the Cork District for duty at Cahir. Major C. H. Hale, D.S.O., has been transferred from York to Stensail. Major B. H. Scott, from Edinburgh, has joined the London District for special duty at the War Office. Major T. B. Beach has been transferred from the Woolwich District to the Aldershot Command. Captain H. B. Connell has embarked for a tour of service on the West Coast of Africa. Captain P. Farrant, from Jamaica, has been posted to Birmingham. Captain T. Scatchard, on completion of a course of instruction at the X Ray Institute at Dehra Dun, has been posted to Agra. Captain W. Wiley, from Bangalore, has joined the Royal Victoria Hospital, Netley, for duty. Captain A. M. Rose, from Bermuda, has been posted to Aldershot. Captain G. Ormrod has been transferred from Landour to Roorkee, and Captain L. V. Thurston, from Nowshera, to Peshawar. Captain F. D. G. Howell, attached to the Lancashire Fusiliers on special duty in connexion with anti-typhoid inoculations, has been transferred with the battalion from Chakrata to Multan. Lieutenant D. S. Buist, from Woolwich, has been posted to Kingston-on-Thames.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions of officers of the Indian Medical Service:—To be Colonels: Lieutenant-Colonel Thomas Grainger (dated Dec. 3rd, 1909) and Lieutenant-Colonel George Francis Angelo Harris (dated March 1st, 1910). Captains to be Majors: Godfrey Tate, Roy Fearon Baird, Andrew Thomas

Gage, George McPherson, Alfred George Sargent, Walter Hubert Cox, D.S.O., de Vere Condon, Henry Kirkpatrick, Frederick Durand Sterling Fayrer, Padmakar Krishna Chitale, William Lethbridge, Thomas Hunter, Walter Rothney Battye, George Hutcheson, William Glen Liston, Harold Boulton, Richard William Anthony, Ernest Frederick Gordon Tucker, George Edward Stewart, Frank Stuart Corbitt Thompson, and John William Watson (dated Jan. 28th, 1910). Lieutenants to be Captains: Harold Hay Thorburn (dated Sept. 1st, 1909); Norman Niel George Cowan McVean, Robert Francis Hebbert, James Smalley, William Malcolm Thompson, Francis Hugh Salisbury, and Frederick Charles Fraser (dated Oct. 4th, 1909); Owen Alfred Rowland Berkeley-Hill, Walter Lidwell Harnett, John Drummond Sandes, William Percival Gould Williams, Siavax Byramjee Mehta, Alexander Harper Napier, Gilbert Holroyd, Arnold Egbert Grisewood, David Livingstone Graham, Pheraya Kharsedji Tarapore, Roger Brighouse Nicholson, George Staunton Husband, James Alexander Cruikshank, John Alfred Steele Phillips, Dwarkanath Dharmaji Kamat, Ernest David Simson, Alexander Frederick Babonau, and Patrick Manson Rennie (dated Feb. 2nd, 1910).

The provisional promotion of Lieutenant Joseph Frain James to the rank of Captain is cancelled.

His Majesty has also approved of the following retirements: Colonel Henry Kellock McKay, C.B., C.I.E. (dated Dec. 3rd, 1909); Lieutenant-Colonel Arthur Bown and Lieutenant-Colonel Joseph Sykes (dated Dec. 14th, 1909); Lieutenant-Colonel William Henry Burke (dated Jan. 1st, 1910); Lieutenant-Colonel James Cort Marsden (dated Feb. 10th, 1910); Colonel Roderick Macrae (dated March 1st, 1910); Colonel Robert Davidson Murray (dated March 29th, 1910); and Lieutenant-Colonel John Anderson and Lieutenant-Colonel George Hart Desmond Gimlette, C.I.E. (dated April 1st, 1910).

Lieutenant-Colonel E. P. Frenchman, Inspector-General of the Jail Department in Burma, has been permitted to retire from April 4th. Lieutenant-Colonel C. E. Sunder has been appointed civil surgeon at Patna, vice Major B. Oldham, appointed to the medical charge of the 24th Pergunnas at Alipore. Lieutenant-Colonel J. K. Close, civil surgeon at Bahraich, has been transferred to Benares, vice Major J. M. Crawford, granted leave. Major R. Heard, late civil surgeon of Simla, has been appointed Professor of Midwifery at the Medical College, Lahore. Major J. W. F. Rait officiates as civil surgeon, Hooghly, during the absence on leave of Lieutenant-Colonel C. M. Crawford. The services of Major F. O. Kinealy, 24th Pergunnas, have been placed at the disposal of the Home Department of the Government of India during his employment as civil surgeon of Simla. Major C. Milne, civil surgeon, Gorakhpur, has been granted 17 months' leave from India. Major H. Bennett has been appointed to officiate as civil surgeon of Ahmedabad during the absence on leave of Major T. Jackson. Captain W. S. McGillivray has been granted 18 months' combined leave from India. Captain E. C. Hepper has been appointed to officiate as civil surgeon, Bahraich, vice Lieutenant-Colonel J. K. Close. The services of Captain E. C. Taylor have been placed at the disposal of the Foreign Department for civil employment in the North-West Frontier Province. Captain W. Lapsley has been transferred from Jaunpur to Azamgarh, vice Major W. Selby. Captain W. T. McCowen has had his leave extended by six months on medical certificate. Captain A. W. Overbeck-Wright has been appointed to the charge of the Central Jail at Dacca during the absence on leave of Major E. R Parry. The services of Captain J. J. Urwin has been permanently placed at the disposal of the Government of Bengal. Captain C. W. F. Melville, Allahabad Brigade, has been granted 18 months' leave. Captain J. H. Burgess has arrived home on leave from India. Lieutenant W. D. Keyworth, in medical charge of the 9th Hodson's Horse at Cawnpore, has been transferred to the officiating medical charge of the 7th Rajputs at Dinapore.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Edward Torriano Holland to be Lieutenant (on probation), (dated March 28th, 1910).

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd Wessex Field Ambulance: Major Alfred B. Soltau to be Lieutenant-Colonel (dated April 1st, 1910).

1st Northern General Hospital: Frederick Charles Pybus to be Captain, whose services will be available on mobilisation (dated March 17th, 1910).

For attachment to Units other than Medical Units.—Robert Neilson Wallace to be Lieutenant (dated March 19th, 1910).

Attached to Units other than Medical Units.—Lieutenant John McWatt resigns his commission (dated Feb. 23rd, 1910).

Captain Thomas Evelyn Fielding, R.A.M.C., to be an Adjutant of a School of Instruction (dated April 2nd, 1910).

DEATHS IN THE SERVICES.

Lieutenant-Colonel Claude Stephen Sparkes, R.A.M.C., at the Cambridge Hospital, Aldershot, on April 23rd, aged 51. He entered the service as surgeon in 1885, was promoted surgeon-major in 1897, and reached the rank of lieutenant-colonel in 1905. He served with the Sikkim Expedition of 1888, including the engagement at Kotkai (medal with clasp), and in 1902 he took part in the operations in the Transvaal, in the Orange River Colony, and in Cape Colony (Queen's medal with four clasps).

THE UNVERSITY OF LONDON OFFICERS' TRAINING CORPS.

A full parade of the Officers' Training Corps will be held on Presentation Day at the University of London, which has been fixed for May 18th. Some 860 cadets and 30 officers will attend, and at the conclusion of the Presentation Day ceremonies the contingent will march past the Chancellor and the members of the Senate. At 6 P.M. a service will be held in Westminster Abbey, when the Dean of Westminster will preach the sermon, and at 7.30 P.M. the members of the Officers' Training Corps will dine together at Victoria Station Restaurant.

THE BRITISH RED CROSS SOCIETY.

On May 2nd the Lady Mayoress of the City of London presided at the Mansion House over a meeting convened in furtherance of the City of London Branch of the Red Cross Society. The Lady Mayoress explained that ten voluntary detachments for men and ten for women would probably be formed, and that steps would be taken for expanding the general hospitals and establishing convalescent homes. Representatives of large business establishments promised to bring the subject before their employees and expressed their intention of establishing classes and affording facilities for lectures on their premises.

The Mayor of Lewes, Alderman G. Holman, presided over a meeting at the Lewes Town-hall on April 26th, which was convened under the auspices of the local division of the Sussex Branch of the Red Cross Society. The advantages of field-training were pointed out and the suggestion that a camp should be started in the summer was favourably received.

The first Voluntary Aid Detachment in Cornwall has been formed at Portleven. Mr. H. W. Spaight, L.R.C.P., L.R.C.S. Irel., the commandant, has raised a full detachment of 24 members.

Mr. J. S. C. Davis, the county director of the Devonshire Voluntary Aid Organisation, has issued a little "Handbook for Workers," which explains the aims and objects of the society, and gives information as to recruiting, conditions of service, details regarding equipment, and so forth.

THE ROYAL SANITARY INSTITUTE.—A sessional meeting of the institute will be held in Hereford on Friday, May 27th. The members will meet at the town-hall, Hereford, at 3 P.M. and proceed to visit the Hereford Garden City and Messrs. Godwin and Thynnes' Encaustic Tile Works. At 5 P.M. discussions will take place in the town-hall as follows:—Country Schools, Disposal of Refuse Matter, to be opened by Dr. D. D. Gold, D.P.H., medical officer of health of Herefordshire; Road Tarring in Districts of Small Rateable Value, to be opened by Mr. R. G. Gurney, P.A.S.I., surveyor to the Ledbury urban district council; Storage, Filtration, and Other Methods of Purification on a Large Scale of River Water used for Drinking Purposes, to be opened by Dr. J. W. Miller, D.P.H., medical officer of health of Hereford City. The chair will be taken at 5 P.M. by Mr. H. D. Searles-Wood, F.R.I.B.A., chairman of the council of the institute. Tickets for admission of visitors may be had on application to Mr. G. H. Jack, C.E., county surveyor and architect, Hereford, who is acting as the local honorary secretary of the meeting, and of Mr. E. White Wallis, secretary.

Correspondence.

"Audi alteram partem."

THE CONSTITUTION OF THE PRISON COMMISSION.

To the Editor of THE LANCET.

SIR,—With reference to your leading article on the Prison Commission in your last issue I beg to be allowed to state the following facts.

On the occasion of my retirement from the office of Commissioner of Prisons last February I had the honour to be asked by the Home Secretary whether I would continue my services, in so far as they were of a medical nature, for a term of five years. On my acceptance of this proposal Lord Gladstone appointed me medical adviser to the Prison Commissioners, and also Director of Convict Prisons, with a seat and voice at the Prisons Board such as I have had ever since my first appointment as Commissioner.

The medical work which now devolves upon me is the same, both in nature and quantity, as that which I have always hitherto carried out. This work occupied in the past little more than one-sixth of the time I devoted to my official duties; it now occupies about two half-days a week, besides causing a fluctuating amount of correspondence. Having now, however, more time at my own disposal, I am able to give voluntarily more attention to any important general question that may arise affecting the medical side of prison work.

I am, Sir, yours faithfully,

Portland-place, W., May 2nd, 1910. H. B. DONKIN.

*** We are glad to learn that Dr. Donkin's position at the Prisons Board in respect of seat and voice is unaltered. We are sure that the Board for the time being gains by receiving medical services from him, while he is unfettered by other official duties. But we regret the exclusion from the Board of a full Commissioner who is also a medical man.—ED. L.

MR. LITTLEWOOD'S METHOD OF PERFORMING THE INTERSCAPULO-THORACIC AMPUTATION.

To the Editor of THE LANCET.

SIR,—The interest which will be aroused by Mr. C. B. Lockwood's paper in THE LANCET of April 30th upon amputations at the hip and shoulder induces me to draw attention to a method of performing the interscapulo-thoracic amputation which owes its inception to my colleague, Mr. H. Littlewood. Instead of carrying out the amputation from the front and tying the vessels as soon as the clavicle has been divided, Mr. Littlewood performed the operation from behind and divided the vessels last. Shortly described, the operation was begun by the usual skin incisions and division of the clavicle. Then the operator, standing behind the patient, reflected the posterior flap sufficiently to expose the muscles inserted into the posterior border of the scapula. These muscles were raised upon the finger and divided with scissors, and near the upper angle the posterior scapular artery was divided and clipped at once. As the scapula was dragged away from the thorax by the assistant, who held the arm, the trapezius was put on the stretch and divided, the omohyoid was cut, and the suprascapular vessels were secured, before division, as they ran to the notch. The large nerves and the vessels now stood out as a big cord. The former were divided, and as they started apart the white artery was exposed for a considerable length. It was divided between two clips, and then the vein was exposed and similarly dealt with. A few cuts of the knife severed the pectorales major and minor, the latissimus dorsi, and the serratus magnus, and completed the amputation.

There can, I think, be no question that performed in this way the interscapulo-thoracic amputation is a much simpler operation than that associated with Berger's name. The real difficulty of Berger's operation lies in the preliminary ligature of the vessels after division of the clavicle. In a muscular or a short-necked patient they may lie at a considerable depth, and before they are satisfactorily exposed a good deal of bleeding may take place. Moreover, the position of the vein in front of the artery may add very considerably to the difficulty of tying the artery first; whilst if the axilla is filled up by a large tumour pressing forwards the pectorals and increasing the vascularity of the soft parts in the neighbourhood—a not uncommon condition where this amputation is called for—the difficulty becomes formidable.[1] But by Mr. Littlewood's method there is *no* difficulty in dealing with the vessels. They present themselves to the operator in the right order without any need for careful dissection and at the close of an operation which except for the skin incision might almost be considered bloodless. I have had experience of both methods and the amount of blood lost in the posterior operation is decidedly less than in the anterior.

Another point that has a bearing upon the shock is the time occupied. Mr. Littlewood's method is much more speedy. Roughly, I would say that it takes half or at most two-thirds of the time required for a Berger's amputation. I have always been astonished at the small amount of shock that follows this big amputation. Of the four cases I have had, in not one was there the least need for transfusion, and of the three that were done for growth the rapidity of recovery after the operation was striking. No doubt this is due, as Mr. Lockwood points out, to prevention of loss of blood, but this object is just as well secured by Mr. Littlewood's method as by M. Berger's. To those who have tried both plans the posterior operation will, I feel sure, be much preferred, and I have very little doubt that in due time it will become the operation of choice. Mr. Littlewood has shown so little disposition to publish much of his good work that I have sought his permission to rescue this little portion of it from oblivion—partly from a feeling of loyalty to a friend, and partly because there are many surgeons who I am sure will be glad to know of it.

I am, Sir, yours faithfully,

Leeds, May 2nd, 1910. R. LAWFORD KNAGGS.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Oct. 12th, 1907, pp. 1011 *et seq.*, an article was published on a surgical instrument types of which have been in universal use for some 30 years or more. The article dealt with my attempt to construct an instrument which should combine the advantages of most of the types then in use. Although the matter is an experimental one, and consequently certain small but essential measurements in my instrument have since been altered chiefly at the representation of friends, the main type remains the same, and the original makers (A) have now stamped its measurements and design for purposes of reproduction by means of certain bosses and templets in their possession. In the experimental stages of the work they devoted much time, skill, patience and money to the subject for which they might reasonably expect some return. Now the originator of any instrument in surgery does not by the etiquette of his profession patent his invention, neither does he make a penny out of it. He places it at the disposal of the profession and if they back him up in the matter, as to a large extent they do and as I think they should do, they will insist on having the actual article made by the original maker, thereby enabling him to recoup himself. Unless this is done there is no incentive to progress, because it is a losing game from the instrument maker's point of view. At the same time it is recognised that the surgeon should not advertise the firm of instrument makers. The question arises, "Can the originator's name under these circumstances be regarded as a trade description or can it not?" If the design is registered or patented I believe it can, and as such it could be infringed, but if not, I believe, strictly speaking, it cannot.

It has come to my knowledge that recently another large and respected firm of instrument makers (B) have sent a traveller round the West of England, and doubtless by now to other districts too, showing an instrument with my name

[1] Vide a most instructing footnote, Jacobson and Rowlands's Operations of Surgery, vol. i., p. 225.

attached to it as a trade description. I have examined and measured this pattern of instrument. In the main essential it is 66 per cent. wrong, and this affects two other important factors in the design to the extent of 40 per cent. and 20 per cent. respectively. In one other essential particular it is radically wrong and in five others partially so. In general finish and in several small details it differs from the original. The price is 30 per cent. less. This firm is not the only one which has "pirated" in this manner. At least one other firm (C) has produced an imitation—in fact a much better one—of my instrument that they sell at half the price of the original pattern. Towards the end of last year I wrote to this firm and said that if they sold the instrument as my design they must take steps to guarantee its being exact in every particular otherwise my name must be omitted from all their descriptions. They replied that they would omit my name from their catalogue and advertisements. I also said that in any case I would on no consideration whatever authorise more than one firm as a manufacturer of any instrument designed by me.

That a great injustice is done to at least two parties by this state of affairs is clear. The question arises as to whether it can be remedied. If the instrument makers themselves would agree to be agents for one another, I believe there would not be any great difficulty. Incidentally I must dissociate myself entirely from any responsibility as to design, measurement, material or method of manufacture in the case of any instrument or appliance bearing my name unless it is made by the firm which I may employ in the first instance. Inasmuch as a scheme is now being tested which, if the results are good, will be worked up into a practical form, I am anxious that this question should be raised and, if possible, fully ventilated.

This letter is entirely disinterested.

I am, Sir, yours faithfully,

April 28th, 1910. G. H. COLT.

THE MIDWIVES BILL AND POOR-LAW RELIEF.

To the Editor of THE LANCET.

SIR,—So far as they are concerned, I do not think that medical practitioners will much care what authority pays the fee, so long as a proper payment is guaranteed. Mrs. Sidney Webb's objection to these fees being paid by the guardians appears to me based on slender foundations. All services given gratuitously by the State on account of the poverty of the recipients are pauperising and tend to destroy the independence of the individual, whether given by the guardians or by any other local authority, and for that reason will always carry some stigma with them. The object of the present Bill is to enable poor lying-in women, otherwise unable to get medical assistance without delay at critical periods, to obtain the prompt attendance of a medical practitioner when summoned by a midwife in charge. This is impossible unless a proper fee is guaranteed, and regarding the analogy of this kind of relief with ordinary Poor-law relief it might be considered that the proper authority to pay these fees would be a Poor-law authority. It might be thought from Mrs. Webb's letter that this Bill proposed to grant to all lying-in women in charge of midwives a right to medical attendance in the case of emergencies at the cost of the State, irrespective of their ability to pay. But its object is only to furnish this assistance when the patient's husband cannot defray the cost. If there is to be no inquiry into the circumstances of the patient and no attempt to recover the cost from those able to pay, it would soon result that all employing midwives instead of doctors would be guaranteed free medical aid in emergencies, and the little midwifery practice still in the hands of the latter would be further jeopardised. Mrs. Webb's desire that these fees should be paid by authorities who have no machinery for investigating the means of those claiming them certainly does support Mr. Fremantle's contention, that she wishes for no inquiries of any kind; that she is in favour of the State paying the doctor's fee, whatever may be the financial position of the patient's husband; and in this she will get little professional sympathy. The question of deterring deserving applicants by reason of inquiry into their means does not arise in these cases. The midwife for her own sake, and without consulting the patient, must always call in the doctor or be guilty of neglect of duty. Neither is there any cogency in the quotation from the report of a midwives' meeting. What the midwives complain of is officiousness on the part of the relieving officer. In order to carry out necessary inquiries there could be no need to make the visits complained of till after the patient was out of all risk of danger. Such abuses might easily be checked if public attention were drawn to them. I confess I am unable to see any analogy between emergencies in the course of parturition and street accidents, and I also fail to follow Mrs. Webb in some of the points she would appear to make—e.g., what does she mean by the following: "Because the board of guardians has chosen to pay (not to them) a fee to a doctor, whom Parliament (not they) has chosen to have called in." If the neighbour of a poor person taken in labour without her consent applies to the Poor-law authorities for aid, and the Poor-law doctor is duly sent for and afterwards receives his fee from the guardians, it appears to me there is a striking parallel between such a case and that quoted by Mrs. Webb. The volition of the patient in each case may be practically the same, and in each case the guardians will be acting under statutory obligations. I quite fail to see the importance of anything that Mrs. Webb has proved by this illustration. The woman requires medical aid, and is unable to pay for it; it is therefore supplied by the State without any regard to her volition in the matter.

I am, Sir, yours faithfully,

MAJOR GREENWOOD,
Honorary Secretary, Poor-law Medical Officers' Association of England and Wales.

London, E.C., April 23rd, 1910.

A QUESTION OF MEDICAL CERTIFICATES.

To the Editor of THE LANCET.

SIR,—My literary avocations having taken me into other fields of work for a good many years now I have got a little out of touch with the general pulse of the profession, and therefore should be very glad of your opinion on a point that strikes me, in my semi-retirement, as affecting the very heart of its civic repute. It is this: Should any corporation be allowed to discriminate between one duly qualified medical man and another in the matter of certificates of illness? and is it consistent with professional etiquette for a medical man, however distinguished, to examine a patient by order of such a corporation after that patient has already obtained from his own medical attendant a certificate that he is temporarily unfit for duty?

That point has been presented to my mind in this way. Taking some active interest (as a mere humble ratepayer) in the municipal orchestra started about two years ago by the Brighton town council, last summer I had occasion to study the contracts of agreement between our musical director and the instrumentalists he is deputed to engage. In the said contracts for the current year I was amazed to find a brand-new clause, laying it down that "illness will not necessarily be deemed a satisfactory reason for absence unless certified to be such by a medical certificate given by the medical officer of health for Brighton or some other medical practitioner nominated by the corporation for the purpose." To my old-fashioned notions this stipulation seemed so gross an insult to the whole profession that I believed no official would ever dare enforce it; but I was mistaken. Last week a member of our municipal orchestra sent in to the musical director a certificate from a duly qualified medical man in general practice that he was unable to return to work for the time being; next morning he received from the medical officer of health the following letter, posted the night before: "I have been asked by the town clerk to call upon you to-morrow forenoon in order that I may give him a certificate as to your present illness.—I am, yours faithfully, &c."

I ought to mention that before actually paying that call the medical officer of health apprised the instrumentalist's own medical attendant by telephone that he had been requested to do so. But I should like to hear your public opinion, as said, on what appears to myself not only a serious hardship (by no means the sole one in these contracts) to our employees, but also a slur on the profession at large.

I am, Sir, yours faithfully,

WM. ASHTON ELLIS, M.R.C.S. Eng., L.R.C.P. Lond.

Brighton, April 25th, 1910.

*** We consider the stipulation that these sick certificates should hold good only if signed by the medical officer of

health or some medical man nominated by the corporation to be an unfortunate one. There is no infringement of ethical principle in the medical officer of health obeying the instructions of his authority, and the appearance of such is removed if the private practitioner is duly communicated with by this public officer. If another private practitioner is instructed to supervise a colleague's certificate he will be well advised to refuse. The regulation looks to us like an imputation upon both the practitioner and his patient, and the corporation ought to be able to deal with suspected malingering in a more satisfactory manner.—ED. L.

FEMALE HÆMOPHILIACS AND *DE NOVO* CASES OF HÆMOPHILIA.

To the Editor of THE LANCET.

SIR,—Professor Osler's admission that he derived pleasure from kissing the chastening rod reflects as much honour on himself as upon the chastiser. I must, however, disclaim membership of the "new iatro-mathematical school." I have often wondered whether any individual has been created with a more rudimentary mathematical centre than myself. My record in mathematics is black. I can, indeed, never efface from my memory a painful communication I received from the Senatus Academicus of the University of Aberdeen after I had stood for my *preliminary* medical examination. It was not like a Foreign Office communication. There was no mistaking its purport. It bore the simple words, "Rejected in algebra."

My endeavour has been to collect and sift the observations on hæmophilia in order to present to the mathematical school a collection of homogeneous iatric data. If "biting Boreas" was let loose it was only because the logician teaches us that "the assertion of a fact wholly beyond the reach of evidence for or against is to be held as untrue" as far as the collection of positive data is concerned. All I asked for was *evidence* of hæmophilia in females, and the evidence must be of a very convincing nature before the existence of such a condition can be held as proved. As Professor Osler suspects, I am not convinced by his account of the girl, nor apparently is Professor Osler himself. "We are not obliged to show that a thing is not; the burden lies upon whoever maintains that the thing is."[1]

I am, Sir, yours faithfully,

London, E., May 2nd, 1910. WILLIAM BULLOCH.

A SCIENTIFIC REPORT AND AN EXPLANATION.

To the Editor of THE LANCET.

SIR,—We recently published in a circular letter to the medical profession, and also in pamphlet form, a report which we had obtained from Dr. E. E. Klein with reference to our oatmeal stout. When we obtained this report we assumed that we were at liberty to publish it in any form which we chose, but Dr. Klein did not understand that we were intending to use it for advertising purposes. Having regard to Dr. Klein's position in his profession, we think it fair to him to make this explanation and to indicate that the publication was made under a misapprehension.

Yours truly,

Croydon. A. C. S. & H. CROWLEY.

[1] Bain: Logic, Induction, 1873, p. 152.

DONATIONS AND BEQUESTS.—Under the will of the late Miss Elizabeth A. Winckley of Leigh, Lancashire, the Leigh Infirmary will receive £1000.—By the will of the late Sir Walter Scott, Bart., the Home for Crippled Children, Gosforth, and the Northern Counties Orphan Institution for the Deaf and Dumb will each receive £250; the Fleming Memorial Hospital for Sick Children, Newcastle-on-Tyne, will receive £500; and the Royal Infirmary, Newcastle-on-Tyne, £1000.

SANITARY BULLETIN FROM THE NEAR EAST.

(BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

Plague in Jeddah.

THE outbreak of plague in Jeddah has taken on a considerable extension in the last few weeks. The following figures are in continuation of those published in my last letter (THE LANCET, March 26th, p. 891):—

Week	ending	Feb.	20th,	0	cases,	0	deaths.
,,	,,	,,	27th,	3	,,	3	,,
,,	,,	March	6th,	12	,,	12	,,
,,	,,	,,	13th,	6	,,	6	,,
,,	,,	,,	20th,	11	,,	10	,,
,,	,,	,,	27th,	10	,,	10	,,
,,	,,	April	3rd,	18	,,	18	,,
,,	,,	,,	10th,	12	,,	13	,,

The total number of cases since the beginning of this year's outbreak has been 77 and of deaths 76. It is probable that these figures are below the truth, as there has always been difficulty in obtaining knowledge of the cases; and this is further shown by the fact that all but one of the known cases have ended in death (or been discovered only after death), thus showing that practically none of the slighter cases come to the knowledge of the authorities. This is the fifth consecutive year in which plague has become epidemic in Jeddah. In 1906 the outbreak lasted from May 29th to July 27th, and there were recorded 72 cases and as many deaths; in 1907 the outbreak lasted from Jan. 8th to May 30th, and there were 365 cases with 354 deaths; in 1908 the epidemic began on Jan. 14th and ended on March 30th, 71 cases with 68 deaths being recorded; and, finally, in 1909, the outbreak (which began on Dec. 16th, 1908) lasted until April 21st, and 178 cases with 160 deaths were reported. With the approach of the summer season it may be expected that the present outbreak will soon begin to decline. At the moment of writing, news has been received that the acting sanitary officer of Jeddah has himself unfortunately contracted the disease. He had been occupied in a bacteriological study of the disease, but it is not yet known whether this is a case of "laboratory plague," or whether he contracted the infection in the ordinary way.

One fatal case of plague was reported from Mecca, on March 12th; details are lacking, but presumably the case was imported from Jeddah.

Plague at Bushire.

Three cases of plague were recently reported from Bushire, in the Persian Gulf; here also details are lacking. One telegram suggests that the infection came from the Bahrein Islands, but no news has been received of the presence of the disease there.

Plague in Beirût.

For some years past occasional sporadic cases of plague have been reported from time to time as occurring in Beirût. On the last occasion (in November last)[1] three such cases occurred. On the 8th of the present month news was received of another case, pneumonic in character; the patient, a girl aged 19 years, belonged to the staff of a travelling circus, which had come to Beirût from Smyrna. Shortly before two deaths had occurred among the staff of this circus; the first was that of a girl aged 15 years, who died after half an hour's illness that began during her gymnastic exercises; the second was that of a child a few months old, who died after 24 hours' illness, with some suspicious symptoms. In the former case, according to a later telegram, death was due to heart disease. The pneumonic patient died in the French hospital in Beirût. The circus has been removed outside the town and other measures have been taken.

Plague in the Kirghiz Steppes.

The latest news from these endemic plague centres is as follows. In the camp of Bodai (Astrakhan government), between Feb. 11th (24th) and 16th (March 1st), 12 new

[1] See THE LANCET, Dec. 18th, 1909, p. 1859.

cases were seen; 2 patients recovered and 14 deaths occurred; the totals from the beginning of the outbreak here had been 23 known cases and 31 deaths. At Novaia Kazanka, in the Kirghiz steppes, 5 cases and 5 deaths were recorded between Feb. 12th (25th) and 18th (March 3rd); the totals here since the outbreak began on Feb. 7th (20th) had been 13 cases, with 11 deaths.

The Recent Pilgrim Season at Camaran.

The pilgrimage of 1909–10 was very numerously attended. So far as concerns the lazaret of Camaran (at the south end of the Red Sea) it was the third largest pilgrimage since that institution came into existence nearly 30 years ago. The largest known Haj in that period was that of 1906–07 when 44,333 pilgrims passed through the lazaret; the second was that of 1907–08 when the pilgrims numbered 37,750; and the third, that of 1909–10, in which the lazaret received 36,361 pilgrims. In the year 1908–09 the corresponding figure was only 30,675. It is of interest to note that of the 36,361 pilgrims who arrived at Camaran this year, 35,588 were carried by steamers and only 772 by sailing ships. Of the steamers, which numbered 44, 33 were under the British flag, and these carried 27,482 pilgrims, or 77 per cent. of the whole. The largest number of pilgrims on any single ship was 1459. Of the whole 36,361 pilgrims, 17,305, or nearly half the total number, were Indians; 10,382 were from the Dutch East Indies; 2439 from the Malay Peninsula; 1605 were Afghans; 1089 from Irak Arabi (the regions to the north of the Persian Gulf); no other race furnished a figure exceeding a thousand. The period of quarantine varied from 24 hours to 7 days, the latter being the maximum now imposed on arrivals from Indian ports (provided, that is, that no case of plague or cholera has actually occurred on board; should such cases occur the quarantine is raised to 10 days).

The season at Camaran was a relatively healthy one. During the voyage to the island 140 deaths had occurred on the various ships, 54 in number, above referred to. Most of these deaths were ascribed to "exhaustion and debility" (77 in number); 13 were due to "syncope," 12 to "malaria," and the rest to various other diseases. During the stay of the pilgrims in the lazaret 290 patients were admitted to hospital, and of these 149 died. Malaria was the predominating disease (with 111 cases and 49 deaths), and next in order of frequency "exhaustion and debility" (with 61 cases and 45 deaths); respiratory disease accounted for 55 cases and 38 deaths; and diseases of the alimentary canal for 36 cases and 6 deaths. All these last occurred in the month of Ramazan and appeared to have been caused by the sudden change of *régime* in that month of fasting and feasting. No case or suspected case of plague or cholera was observed.

It will be recalled that early last year a new system of excreta disposal was introduced in one of the "cordons" at this lazaret. The past season was the first complete season in which the new system had been under trial. The cordon in question was purposely occupied throughout the entire season so as to put it to as thorough a test as possible. Pilgrims from 13 ships, numbering 11,842 in all, were interned successively in this cordon. The cordon was occupied during 55 days. In spite of this severe test, the new system (the nature of which was described in THE LANCET of June 1st, 1907, p. 1521) has given most satisfactory results. The director of the lazaret, in his annual report, makes the following calculation. Allowing 150 grammes of solid matter, and the small amount of one litre of urine per pilgrim per day, he estimates that 1776 kilogrammes (over 1¾ tons) of solid matter and 11,842 litres (nearly 12 fluid tons) of urine entered the "*fosses à fond perdu*" to which the contents of the trough-closets are conducted. In addition the eight flushing tanks of 40 gallons each being set to go off every two hours, some 1450 litres of water per day also entered the "*fosses.*" As the cordon was occupied during 55 days no less than 828,740 litres (over 828 fluid tons) of mixed water and sewage matter had to be disposed of. This enormous quantity was easily absorbed by the "*fosses.*" In concluding his report on this question the director states that, in his opinion, the problem of the disposal of excreta in the Camaran lazaret—a problem which has given more trouble than any other since the lazaret was created—may be considered henceforth as satisfactorily solved.

Constantinople, April 15th.

THE GERMAN SURGICAL CONGRESS.

(FROM OUR BERLIN CORRESPONDENT.)

THE annual congress of the German Surgical Association was held in Berlin from March 30th to April 2nd, Professor BIER (Berlin) being in the chair.

Operations on the Brain.

Professor KRAUSE (Berlin) read a paper on Operations for Non-Traumatic Epilepsy. He said that he had operated during the past eight years upon 80 epileptic patients, of whom 50 suffered from Jacksonian epilepsy and 30 from general epilepsy. When the disease was of toxic origin, as in cases of lead poisoning, or was due to some acute infectious disease or to hysteria there was, of course, no indication for surgical intervention. The operable cases were those in which the epilepsy was produced by a growth or as a sequel of infantile paralysis. There were, moreover, cases in which the cause could not be found, and in which a certain predisposition to epilepsy must be assumed to exist. The operation was especially successful in the first category when no cerebral pressure and no "Ausfall" symptoms were present. With respect to the second category, he said that the epileptic fits might occur very late after the primary disease, even at intervals varying from 4 to 20 years. In every instance the cerebral centre for those muscles which were the first affected by the fit must be removed. To find the respective motor regions the faradic current must be applied to the cortex after the latter had been made accessible by trephining, localisation by mere observation being impossible. Professor Krause recommended for the faradic irritation long and fine electrodes; the current must of course be very weak, so weak that when applied to the tongue it must not cause muscular contractions but only a prickling sensation. He found, in accordance with the experiments of Professor Hi'zig and Professor Sherrington, that only the central lobe was stimulated by the faradic current. By irritating certain points of the central gyrus he could ascertain three motor regions respectively for the upper and for the lower extremity and for the neck. When the motor centre was found excision was performed, the field of operation in certain cases extending over an area of 26 by 30 millimetres and reaching down to the white substance. Paresis of the speech centre might sometimes occur, but usually disappeared very soon. Professor Krause obtained five complete recoveries and in many instances considerable improvement. In general epilepsy the results were less favourable, as of 30 cases only one patient was considerably improved, three were somewhat improved, and the remainder were unchanged. He generally made a valvular opening, according to the procedure described by Professor Kocher of Berne, in order to lessen the intracranial pressure. Notwithstanding the unfavourable nature of the results in general epilepsy, he recommended the operation in cases where internal treatment has proved useless.

Professor TILMANN (Cologne) discussed the question of operations for traumatic epilepsy. He said that the traumatic origin of epilepsy was sometimes doubtful in cases where the fits occurred only some years after the accidents. It was of the greatest importance that in the treatment of injuries of the skull the possible occurrence of post-traumatic epilepsy should from the beginning be kept in mind. Primary trephining was therefore often to be recommended. Of 300 cases described in medical literature no trephining had been performed in 291. He had himself operated on 20 cases. In 50 per cent. there were an abnormal tension of the dura mater, œdema of the pia mater, and sometimes scars and concretions. In a second series of cases cysts were present, and sometimes periostitis and exostosis. There was only one instance in which the examination proved negative. An operation was always indicated in these cases. The skull must be opened at the place of the injury; the scars, concretions, and cysts must be removed, and œdematous fluid must be evacuated by puncture. In Professor Tilmann's opinion a single complete operation was preferable to one performed in successive stages. In 20 cases he had 12 recoveries, 1 case of improvement, and 1 death; 4 cases were not improved and 2 were still under treatment.

Professor FRIEDRICH (Marburg) reported the results of 25

cases operated on by him during the last 11 years. He divided the cases into three groups. The first group included 11 cases in which the operation had been performed from 7 to 11 years ago. One patient recovered completely, one recovered with slight attacks of temporary loss of consciousness, three were improved, and the remainder were not improved. In the second group, consisting of 6 cases operated on from three to seven years ago, 2 patients recovered, 1 was improved, and the others were unchanged. The third group consisted of patients operated on during the past three years; 2 of them recovered, 1 was improved, and the remainder were unchanged.

Professor GARRÉ (Bonn) uttered a warning against too frequent and too early operation for genuine epilepsy; he said that such operations were justifiable only in cases in which internal treatment had absolutely failed.

Dr. HESSE (Stettin) emphasised the value of the puncture of the brain devised by Dr. Neisser and Dr. Pollak. He said that it was indicated for hæmatoma after severe injuries of the brain, where the local symptoms were concealed by grave general symptoms, such as coma and disordered states of the circulation and of the respiration; it was also indicated in desperate cases when the patient could not support a radical operation; and finally, in cases where the intracranial pressure developed after days or weeks. Puncture and aspiration might be followed by complete recovery in such cases.

Operations on the Spine.

Professor HILDEBRAND (Berlin) recommended somewhat active intervention in the following three affections of the spine: 1. In traumatic lesions of the vertebral column where compression of the spinal cord was liable to be produced by hæmorrhage. In these circumstances an early operation might prevent irreparable damage to the cord. It was sometimes difficult to make out whether the cord had been totally or partially injured. He had operated for four lesions of the cervical, five of the dorsal, and one of the lumbar vertebræ. 2. In spondylitis. He said that the paresis of the extremities occurring in cases of spondylitis was not always due to compression brought about by vertebral caries, but might also be caused by tuberculous growths filling the vertebral canal, so that such cases could not be successfully treated by extension. An operation was therefore to be recommended when no improvement has been obtained within a few weeks by orthopædic measures. In 9 cases of spondylitis tuberculous growth was present in the vertebral canal in five instances; 2 of these patients recovered, 3 were improved, and 4 were unchanged. 3. In growths of the spine. The making of a diagnosis as to whether a growth was situated in the spine or outside it was somewhat difficult and was, moreover, of no great importance. An operation was always indicated. Of 13 cases 3 died. It was remarkable that the strength of the vertebral column was not at all impaired by laminectomy. Professor Hildebrand had performed 35 laminectomies with 9 deaths.

Operations for Little's Disease.

Professor KÜTTNER (Breslau) explained that the spastic contractions of the muscles in diseases of the pyramidal tracts was caused by the absence of the inhibitory faculty, so that every muscle had a tendency to a maximum reflex contraction, no matter whether a cortical or a spinal lesion was present. Dr. Foerster of Breslau had proposed to interrupt the reflex circuit by a resection of the posterior roots; when this was done the effect of peripheral irritants was so much diminished that contractions no longer occurred. Professor Küttner has performed this operation on ten children who were all bedridden and had rigid limbs. As the children were all rather delicate he divided the operation into two stages; the roots of the second, third, and fifth lumbar nerves and the second sacral nerve were removed. No death had occurred, and there had been a remarkable improvement in the state of the children, who after the operation had undergone orthopædic treatment. The children were shown at the meeting; they were able to walk with the aid of sticks.

Professor KLAPP (Berlin) reported 6 cases of the above operation performed in Professor Bier's clinic with 1 death. In the other instances the operation was successful. Slight spasms reappeared some time after the operation but not to such a degree as to interfere with the use of the limbs.

Professor TIETZE (Breslau) said that he had performed the operation on 8 patients, of whom 2 suffered from Little's disease, 1 from spondylitis, 1 from multiple sclerosis, 1 from myelitis, and 2 from spastic contraction after apoplexy. He had found that the children supported the operation better than the adults, of whom 3 died. The functional results were better in Little's disease than in other affections.

Operation for Stenosis and Rigid Dilatation of the Thorax.

Professor FREUND (Berlin) said that stenosis of the superior aperture of the thorax was caused by a defective development of the cartilage of the first rib. Its sequel was a derangement of the function of the apex of the lung which favoured invasion by tubercle bacilli. At a later stage there might be ossification of the cartilage with subsequent rupture of it leading to pseudarthrosis. The mobilisation of the superior aperture of the thorax by the pseudarthrosis might result in the patient recovering from the tuberculosis. Rigid dilatation of the thorax was generally caused by an affection of the cartilages of the ribs; they showed a yellow fibrillation and cavities leading to an increased volume of the cartilages by which the thorax was brought into a permanent position of inspiration and as the lungs must follow the thoracic walls emphysema was the result. In stenosis of the superior aperture of the thorax mobilisation by resection of a piece of the first rib was indicated; this, however, should only be done in cases where the tuberculous affection had not yet exceeded the border of the second rib. To mobilise total rigidity of the thorax pieces of the second to the fifth costal cartilages might be removed; the operation was, however, indicated only in cases where the emphysema had not yet led to atrophy of the lungs or the diaphragm.

Professor MOHR (Halle) said that when rigidity of the thorax arose from the condition described by Professor Freund the deformity might be improved by operations, but that other forms of rigid thorax must be excluded. The diagnosis might be made by radiography and spirometry to distinguish Freund's type from other rigid types, such as the paralytic and the senile thorax. Professor Freund's type was, moreover, characterised not only by palpable swelling but also by hyperæsthesia of the cartilages. An operation was totally contra-indicated in a paralytic thorax, where it would only increase the existing expiratory condition. Bronchitis and asthma were not only not contra-indications against the operation but were in fact relieved by it. Disorders of the circulation must be controlled by internal treatment previous to an operation, and when this was not possible an operation could not be performed. Operations were also inadvisable at an early stage of the disease and they should be attempted only in cases of real rigidity. With regard to an operation for stenosis of the superior aperture of the thorax accompanied by tuberculosis, Professor Mohr said that he had had little experience, but he pointed out the difficulty of diagnosing the deformity during life, and was of opinion that the patients would certainly not consent to an operation in such an early stage of tuberculosis.

Professor VON HANSEMANN (Berlin) said that he had found in numerous post-mortem examinations that the typical form of tuberculosis of the apex of the lungs showed in the majority of cases stenosis of the superior aperture of the thorax as described by Professor Freund. In his opinion the idea that the predisposition to invasion by tubercle bacilli might be removed by Freund's operation was an excellent one, and he thought that neither an advance of the tubercle bacilli to the region of the third rib nor the formation of cavities was a contra-indication. Dilatation of the right side of the heart was not a contra-indication, the circulation adapting itself to the existing wants. In addition to typical emphysema there was another form dependent upon weakness of the elastic fibres of the lungs and not associated with disease of the cartilages. It did not happen before the thirtieth year of life and was, of course, not operable.

Dr. VON DEN VELDEN (Düsseldorf) reported 10 cases of operation for rigid dilatation of the thorax. The operation was completed in one stage; resection of the cartilages of the second to the fifth rib of one side was sufficient. The necropsy of patients who had succumbed to intercurrent diseases showed that the gap became closed by a bridge of connective tissue which remained elastic. Favourable results for respiration and circulation were ascertained by physiological methods.

Dr. SEIDEL (Dresden), speaking in the discussion, said that his first operations were performed two and two and a half years ago, and that the improvement then effected had continued to the present time. The operated side showed a marked retraction; the circumference of the thorax had decreased and the respiratory extension had increased. There had been no union of the cartilages.

Professor FRIEDRICH (Marburg) said that both the immediate and the permanent results exceeded his hopes. The improvement was the more remarkable as an ossification had occurred. The operation was, however, not without danger, for he had lost a patient on the second day from bronchopneumonia.

Dr. HIRSCHFELD (Frankfort) reported that he had resected the cartilages in a girl suffering from attacks of bronchial asthma, and when this operation had proved insufficient he had performed resection of the manubrium sterni, which had been followed by complete recovery.

Dr. WULLSTEIN (Halle) recommended longitudinal resection of the sternum instead of a resection of the cartilages.

Dr. HARRAS (Hanover) said that resection of the first cartilage had no influence on stenosis of the superior aperture of the thorax and that this was the more to be regretted because the connexion between stenosis and tuberculosis of the lungs was obvious. Tuberculosis of the lungs existed in 25 per cent. of bodies having a wide aperture of the thorax, and in 85 per cent. of bodies showing stenosis of the thorax.

(To be continued.)

THE HUNGARIAN BALNEOLOGICAL CONGRESS.

(FROM OUR BUDAPEST CORRESPONDENT.)

THE Twentieth Hungarian Balneological Congress was opened in the rooms of the Budapest Royal Society of Medicine on April 16th. Dr. ARPÁD BÓKAY, Professor of Pharmacology at the University of Budapest, presided, and most of the Hungarian and Austrian balneological authorities were present.

The PRESIDENT in his opening address gave expression to his regret that fewer addresses would be delivered at this congress than on former occasions, and that among the speakers new names were conspicuous by their absence. Reminding his hearers that this state of things indicated stagnation and a retrograde tendency, he contrasted with it the example of French balneological physicians, who at the close of the season went each year to medical schools and universities for the purpose of study and increasing their knowledge.

Dr. DALMADY ZOLTAN (Tátrafüred) delivered the first address, his subject being the influencing of diatheses by physical methods. He said that diatheses might be divided into three classes—namely (1) those manifested in family relations; (2) those dependent on physiological conditions; and (3) those caused by pathological changes. Biological diatheses could be modified only by means of artificially produced biological mediums, as, for instance, the constant variety of the circumstances of living and certain stimuli causing protracted differences. The chief class of physiological diatheses were due to changes produced by want of exercise; this might be remedied by the use of so-called strengthening methods of treatment. The treatment of diatheses brought about by diseased conditions proceeded on almost the same lines as the treatment of the diseases causing the diatheses.

Dr. V. D. LENKEI delivered the second address, his subject being the atmosphere in the neighbourhood of Lake Balaton (Platten See), and the radio-activity of the water and the underlying strata of this lake. He detailed the procedure by which he measured the radio-activity and described the results arrived at by these measurements.

Dr. SCHULHOF (Hévviz) read a paper on Balneotherapy in Serious Nervous Disorders. He asserted emphatically that as a general rule baths for nervous diseases were not wisely chosen. The Hungarian public were not accustomed to ask their medical advisers before going to a bathing resort; they simply followed the prevailing fashion, and when a certain thermal bathing station was fashionable on account of its amusements they went there. If they had previously obtained medical advice on the subject many of them would have been cautioned against taking thermal baths. Dr. Schulhof, however, believed that there were some nervous disorders in which long-continued hot baths, if properly applied, might be of great benefit.

Dr. KALLOS, a balneologist in Csiz, which has some repute for its iodine waters and was the Mecca of scrofulous patients in Hungary, spoke in regard to artificial mineral waters. He said that the chemical constitution of a natural mineral water might by analysis be ascertained with a high degree of precision, and from this analysis a close imitation might be made artificially, but the artificial product nevertheless did not produce the same therapeutic results as the natural water. He had prepared an artificial iodine water which was in respect of its mineral constituents analytically identical with the natural Csiz water, but he found that in therapeutic efficacy the artificial water was far inferior to the natural one. This was, in his opinion, due to some unknown constituents of the natural water, which chemical analysis had not yet succeeded in discovering.

Dr. FARKAS read a paper on the Effect of Change of Weather on Different Patients. He said that some patients were wonderfully prescient of change of temperature. These "live thermometers," as he called them, could foretell the weather 24 hours in advance. He had a patient who predicted changes in the weather from his sensations of headache, pain in the bowels, and exhaustion.

Dr. TÜMEGI (Balatonfüred) described his experiences with carbonic acid baths in the treatment of heart diseases. He said that the beneficial action of these baths was undeniable. According to his observations, their efficacy depended only on the amount of the carbonic acid constituent and the temperature of the water, the saline constituents being of no importance at all.

Dr. WEISZ EDE showed an apparatus of his own invention for the treatment of lameness or cases in which the movements of the limbs were restricted.

The PRESIDENT of the Congress read a paper on the Indications for the Use of Calcareous Waters. He said that such waters, especially those containing both lime and magnesia, were up to the present chiefly in request as table waters although they were used in certain kidney diseases. He called the attention of the congress to the important part which lime played in the organism, especially during pregnancy and lactation, during the development of the body in childhood, and in connexion with some diseases of the blood. A very pleasant and efficacious way of administering salts of lime was to make the patients drink calcareous mineral waters.

Dr. LÖW read some statistical data as to the attendance of visitors at the Hungarian balneological resorts, and quoted figures from which it appeared that in 200 such resorts there had been 218,283 visitors during 1909, showing an increase of 11,806 over the number for 1908. He also said that Hungary exported mineral waters (chiefly bitter water) to the value of about 10,000,000 kronen (£400,000), as compared with imports to the value of only 1,300,000 kronen.

Several other papers of balneological interest were read during the meeting, and the members of the congress were afterwards entertained at various social festivities.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Insanitary Property in Liverpool.

THE medical officer of health (Dr. E. W. Hope) has published in printed form his annual tabulated statement in regard to the demolition of insanitary property. The net result shows that during the four years 1906, 1907. 1908, and 1909, 1112 insanitary dwellings had been demolished, 311 had been closed and await demolition or reconstruction, and 514 had been reconstructed and rendered sanitary, making a total for the four years of 1937, excluding those in schemes, but still occupied. Of the total named, 874 were dealt with in 1906, 391 in 1907, 317 in 1908, and 355 in 1909.

Public Health Congress in Birkenhead.

The forthcoming congress of the Royal Institute of Public Health, of which His Majesty the King is patron and His

Royal Highness the Prince of Wales vice-patron, will be held in Birkenhead from July 18th to 23rd next. It has a strong and distinguished number of office-bearers, including Mr. W. H. Lever, ex-M.P. for the Wirral Division, the president of the congress, and Dr. R. Sydney Marsden, the honorary general secretary. Sir Lauder Brunton is president of the Section of Preventive Medicine and Vital Statistics. Sir William Ramsay is President of Section II., including Chemistry, Bacteriology, and Meteorology. Sir Thomas Oliver is president of Section III., including Industrial and School Hygiene. Mr. Henry Vivian, M.P., is president of the section which includes Town-planning and Municipal Architecture. Amongst the vice-presidents of the various sections are Sir John William Moore, Sir Rubert Boyce, Dr. W. T. Prout, C.M.G., and Dr. Owen Williams. The list of papers to be read is a long and interesting one. The Earl of Meath will read a paper asking "Are the Tendencies of Present Educational and Social Influences in the Direction of an Unwise Sentimentality, tending to a Weakening of the Moral Fibre of Children, and becoming a Serious Social and Political Danger to the State?" Professor Benjamin Moore will read a paper on the Nationalisation of the Public Health Service, whilst Dr. E. W. Hope (the medical officer of health of Liverpool) will read a paper on the Need of a Quinquennial Census.

University of Liverpool School of Hygiene.

The examination of students who attended the courses of instruction in sanitary science during the past session took place at the University last week. 46 candidates presented themselves for examination, and of this number 33 satisfied the examiners and were awarded certificates of proficiency, entitling them to act as sanitary inspectors. A fair proportion consisted of females. The examiners were Mr. F. Vacher, late medical officer of Cheshire, and Dr. A. A. Mussen, assistant medical officer of health of Liverpool.

May 3rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Edinburgh.

THE half-yearly meeting of the General Council of the University was held on May 4th. The Medical Curriculum Subcommittee presented a long and important report concerning the scope and arrangement of the courses of instruction and the time and arrangement of the examinations for the degrees of M.B. and C.M. Among other recommendations the committee suggests that attendances at classes for instruction in the subjects of the first professional examination shall not be held to constitute any part of the five-years course of professional study, if such attendance has been given prior to registration. But students who present themselves from any recognised institution may be admitted to examination in one or more of the subjects of the first professional examination without attending the University course or courses in such subjects. An elaborate time-table for the whole five years was also submitted.

Annual Meeting and Conference in Edinburgh of the National Association for the Prevention of Tuberculosis.

The annual meeting and conference of this association is to be held in Edinburgh from July 2nd to 5th. The President of the conference is Professor W. Osler; the chairman of the executive is Sir Alexander Christison, Bart.; the honorary treasurer is Dr. R. W. Philip; and the honorary secretaries are Dr. W. Leslie Lyall, Mr. George A. Mackay, of the Local Government Board, and Dr. James Miller. The conference on tuberculosis will occupy July 4th and 5th. An exhibition will be open to the public similar to the exhibitions already held in London, Oxford, and Cambridge. A general committee is being formed, and visitors are expected from the continent and America.

The late Dr. John Smith.

At the weekly meeting of the managers of the Edinburgh Royal Infirmary the following minute was approved, and it was directed that a copy of it be sent to the widow of the late Dr. John Smith:—

The managers desire to record their sincere regret at the death of Dr. John Smith, consulting dental surgeon to the Royal Infirmary. Appointed dental surgeon in 1863, Dr. Smith for twenty-five years discharged the duties of this office with conspicuous ability and acceptance. Dr. Smith's services were frequently sought for by his colleagues on the medical and surgical staff, and his well-known technical skill and ingenuity were very highly appreciated, and proved of much advantage to the institution. On his retirement from the acting staff in 1888 Dr. Smith was appointed consulting dental surgeon to the infirmary, and he continued throughout to take a warm interest in its affairs. The managers are aware of the high honour and esteem in which Dr. Smith was held by the medical profession as well as by the community at large, and they are deeply sensible of the loss the infirmary has sustained by his death.

Drainage of the City of Glasgow.

On May 2nd the Lord Provost officially opened the new sewage-disposal works situated at Shieldhall. The ceremony marked not only the inauguration of the authorised southern section of the city scheme, but also the completion of the entire Glasgow main drainage undertaking. Before the opening of the Dalmarnock works—the first step in the scheme—the whole sewage of the city was discharged without any purification into the Clyde. The main drainage scheme for the collection and treatment of the sewage of Glasgow and the adjacent local authorities was authorised by various special statutes between the years 1891 and 1907. Next to the undertaking of the London County Council the scheme is the largest in the world. The territory included stretches along both sides of the river Clyde for a distance of about 15 miles, limited by the wilderness of Cadder on the north and the borders of Mearns Moor on the south, and extending westward from the Bishop Loch to Duntocher burn. The extent of the drainage area is 41½ square miles. The volume of sewage and the proportion of rainfall to be dealt with, which will originate within the indicated drainage area and which will be treated in the three separate works, is estimated at 250,000,000 gallons per day. The drainage area is divided into three sections, each distinct from the others, with separate works for the disposal of their sewage. It is the last of these works that was opened this week at Shieldhall. The completion of the work will remove from the Clyde the whole of the solid matters of the sewage of Glasgow and the adjacent burghs and will purify the dissolved ingredients to such an extent as will restore the river to a condition which must exercise a most beneficial influence on the health of the vast population residing within the territory affected. Following on this work, it is the immediate intention of the corporation to endeavour to arrive at a definite understanding with the upstream and downstream riparian authorities, who at the present time pollute the waters of the river without the area of the Glasgow main drainage scheme. Attention is also being turned to contamination which enters the Clyde from the various tributary streams, and an attempt will be made to purify the Kelvin, the Cart, and the Leven.

Aberdeen County Committee on Secondary Education: Appointment of Chief School Medical Officer.

At a meeting of the Aberdeen county committee on secondary education held on April 29th Dr. G. Mitchell of Birmingham was appointed to the post of chief school medical officer. There were 11 applicants. Dr. Mitchell is 32 years of age, and a native of Aberdeenshire. He graduated at the University of Aberdeen, M.B., Ch.B. 1903, D.P.H. 1904, and M.D. (highest honours) 1905. He was for nine months house surgeon at the Sick Children's Hospital, Aberdeen, and then studied at the London Hospital and the Hospital for Sick Children, Great Ormond-street, London. For the last six months he has assisted Dr. W. Sisam, medical officer of health of Handsworth, in his work of medical inspection of schools and school children. The salary is £300 per annum, rising by four annual increments of £25 to £400 per annum, with travelling and other expenses.

Aberdeen School Board and Medical Inspection.

The Aberdeen School Board has now reported that it has considered the recent request of the provincial committee for access to certain schools by the medical officer of the committee and by senior students. This facility was sought for observation purposes in connexion with the study of school hygiene and for the employment of the provincial committee's medical officer in the actual medical inspection of certain schools without salary, but under the supervision of the medical officer of the board and subject to his instructions. The chairman drew attention to the result of the board's recent inquiries into the practice on both points in Edinburgh and Glasgow, and moved that the practice

referred to, which worked with no detriment to the interests of the children placed under observation, and with no friction between authorities, be followed in Aberdeen. The board in committee concurred. It was resolved accordingly that reasonable facilities be accorded the provincial committee's lecturer on school hygiene to visit any of the board's schools along with his students for observation purposes, by previous arrangement in every case with headmasters; and for the rest that the board's responsibility for the actual medical inspection of the John-street Demonstration School, of which the provincial committee remains the managers, be left, as in Edinburgh and Glasgow, in charge of the provincial committee's own medical officer if so desired.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Students' Union of the Royal College of Surgeons: Inaugural Meeting.

THE formal inauguration of the Students' Union of the Royal College of Surgeons in Ireland took place on April 30th. The union had its inception in a meeting held on Dec. 16th last, and owes its existence almost entirely to the interest taken in the life of the medical student by Sir Henry R. Swanzy, ex-President of the Royal College of Surgeons in Ireland, and the recent co-opted professor of anatomy at the School of Surgery. As a result the Albert Hall, the old examination hall of the College, has been made the students' common room and comfortably furnished, while the Council has generously undertaken to supply firing and lighting. Mr. J. Lentaigne, the President of the College, who attended in his official robes, made a speech on declaring the union open, in which he dwelt on the great backwardness of the quality of the teaching in his own student days, and the low standard of physical comfort which was provided for the students of the various medical schools. Their social and moral requirements were absolutely uncared for; "the lectures were delivered in a careless, slipshod fashion, so as to give him the least possible amount of value. When the time for the examinations came, in order to have a chance of passing, it became necessary for the student to plunge into a frenzied orgie of cramming, which was called 'grinding.' This left him little solid residue of knowledge for his future career." It is a dark picture of student life, but curiously enough, the Dublin School of Anatomy and Surgery reached the zenith of its reputation when similar methods were in vogue.

The Rev. Thomas Waugh Belcher, D.D., M.D.

In the Rev. Thomas Waugh Belcher a very prominent and popular member of the medical profession has passed away. Dr. Belcher was M.A., M.D., M.Ch., and D.D. of Dublin, M.A., M.B. of Oxford, and F.R.C.P. of Ireland. He was formerly chief librarian and an examiner of the Royal College of Physicians of Ireland and also physician to the Dublin Dispensary for Skin Diseases. Dr. Belcher, after taking Holy Orders, was appointed vicar of a London parish, and later was made rector of Frampton Cotterell, near Bristol, where he remained until his decease. Dr. Belcher was a great authority on "Canon law" in the Church of England, and he contributed various articles and essays on Church matters. He was always interested in medical matters, and was an active member of the Guild of St. Luke. At a recent meeting of the Royal College of Physicians of Ireland a resolution of sympathy was sent to the widow stating that the President and Fellows desired to "record their appreciation of the honour shed upon the College by the varied attainments and learning of their colleague and friend, and to convey to the family of the deceased an expression of sincere sympathy with them in their bereavement."

Health of Belfast.

The report presented at a meeting of the city council of Belfast on May 2nd for the four-weekly period between March 20th and April 16th showed that the death-rate from all causes was 20·6, 7·0 from chest diseases, and 2·7 from zymotics. During the month 96 cases of infectious disease were notified, which is a reduction of 22 as compared with the preceding month, but 39 in excess of the numbers notified in the same period of last year. The decrease is most marked in scarlet fever and erysipelas, the numbers being 38 and 23, as compared with 59 and 30 respectively. Curiously, 2 cases of typhus fever were notified from a house which was clean and with no overcrowding. Every effort was made to trace the source of the infection, but without success. The excessive death-rate in zymotic diseases (higher than in the preceding month or in the corresponding month of last year) was to be attributed to the prevalence of measles and whooping-cough, from which there were respectively 37 and 33 deaths registered, as compared with 1 and 12 in the same period of 1909. A most curious circumstance is the association, so often noticed in Belfast as elsewhere, of measles and whooping-cough.

Belfast Improvement Scheme.

An inquiry into a scheme made by the corporation of Belfast—within the meaning of the Housing of the Working Classes Act, 1890—for the improvement of certain unhealthy areas, and also into an application for sanction to a loan of £116,342 5*s.* for the purpose of carrying out the scheme, was held last week in Belfast by Mr. P. C. Cowan, chief engineering inspector of the Local Government Board, and terminated on April 29th by Mr. Cowan confirming the scheme, with a slight amount of alteration and modification. The inspector regarded the scheme on the whole as a very excellent one.

Health of Lurgan.

Dr. Samuel Agnew, medical officer of health of the Lurgan urban district, has issued an interesting report for 1909. He points out, as an indication of the backwardness of sanitary reform in Ireland, that in the 22 town districts of Ireland with an aggregate population of 1,142,308, the crude death-rate last year was equal to 19·2 per 1000, whereas in the 76 largest English towns it did not exceed 14·7. During the year 1909 the birth-rate for Lurgan was 21·8 (the average birth-rate for the previous ten years was 30·8) and the death-rate 19·6. The zymotic death-rate was 1·3. An account of an outbreak of scarlet fever which occurred in April and May, and which included 64 cases, is given. Dr. Agnew believes that the majority of the cases occurred through articles of white work or handkerchiefs being given out for work from two factories. These articles came into contact with people suffering from the disease. When these two factories, at the suggestion of Dr. Agnew, ceased distributing out-work for some time, and took none back during the same period until after disinfection, the epidemic was stayed. Dr. Agnew refers to the powerful influence of the Women's National Health Association in moulding public opinion, without which, he says, it is vain to hope for any progressive legislation on public health matters in Ireland.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The French League for Physical Training.

THE French League for Physical Training has been recently organised in Paris under the general superintendence of Professor Gilbert. Its objects are the promotion of health, beauty, strength, and alertness among children of either sex, both those who are still at school and those who have completed their school attendance. For this purpose the league relies on rational physical training, in which use is made of (1) systematic movements based on the gymnastic principles of Ling, with additions and modifications suggested by recent scientific research; (2) free movements in active recreation, games, athletic exercises, various sports, and life in the open air; and (3) the personal hygiene of both sexes at all ages. The league is also endeavouring to form athletic associations for adults and to obtain from the State and from the communes the appropriation of grounds and open spaces for the benefit of those who undergo this training. At the first meeting of the league last March a commission was appointed for the purpose of making arrangements to offer a prize for a short, simple, and practical book on physical training for the use of children and adults of either sex. At the next meeting it was resolved to take up the question of laying out children's playgrounds with clean sand in the Paris squares. The members of the league look forward to giving attention successively to the various problems connected with the physical training of the population.

Female University Students.

The female students of the University of Paris have recently formed themselves into an association. Madame Mulon, a medical graduate, who has been elected president of the association, intends to provide certain facilities for the members in connexion with their studies, and to assist them in establishing an office through which appointments may be obtained. The premises of the association will be opened on May 29th, and will include an inexpensive restaurant.

Feeding-bottles with Tubes.

A law which has for several years been greatly desired has now been passed and has recently appeared in the *Journal Officiel*. It relates to infants' feeding-bottles provided with tubes, and declares that the sale, the offering for sale, the public exhibition, and the importation of such bottles are forbidden. It will come into operation three months after promulgation and will be enforced by the inspectors of pharmacies and some other officials. Contravention will be punished by a fine ranging from 25 to 100 francs, and a repetition of the offence may be followed by imprisonment for a period varying from eight days to a month. In all cases where feeding-bottles with tubes have been seized the courts may order their confiscation.

Surgical Lectures by Dr. Doyen.

In accordance with the right which the regulations confer on every Doctor of Medicine, Dr. Doyen applied to the Council of the University of Paris for permission to deliver a free course of lectures in the rooms of the Faculty of Medicine, and the permission in question was duly granted. These lectures, which have for their subject the relations of topographical anatomy to surgical technique, were announced long beforehand, and at 6 P.M. on April 18th an enormous crowd of students filled the large amphitheatre of the École Pratique where the lectures were to be delivered. On making his appearance Dr. Doyen had a very noisy and hostile reception. The shouting and yelling of a portion of the audience combined with the applause of another section created such a din that for a whole hour the distinguished surgeon could not make himself heard and he ultimately withdrew. In the evening M. Landouzy, the dean, wrote to Dr. Doyen informing him that in order to prevent a recurrence of these disorderly scenes the lectures would for the present be discontinued. This decision was received with mingled feelings. Everybody knew that preparations for the tumult had been made by the young *internes* of the hospitals several days beforehand. It was also evident that the Faculty of Medicine, while allowing Dr. Doyen to deliver a course of lectures in its amphitheatre, had not dealt quite fairly with him, for it would not have been absolutely impossible to prevent this demonstration. On a former occasion in a free course of lectures delivered at the Sorbonne by a Mr. Thalamas he expressed opinions regarding Joan of Arc which so greatly shocked the younger members of the university that for a fortnight there was a succession of violent scenes. The lectures were nevertheless continued under the protection of the police, who made several arrests and took measures to secure the liberty of free speech. Dr. Doyen has not been privileged to the same extent, but in order to avoid disappointing many students who were really seekers after knowledge, as well as the foreign medical men whom the announcement of the lectures had brought to Paris, he addressed them in a specially hired lecture-room, admission to which could be obtained only by tickets costing 10 francs. This course of lectures commenced at 6 P.M. on April 25th, the audience being numerous, attentive, and orderly, and the demonstrations given by Dr. Doyen were of such novelty and interest that the Faculty of Medicine might well have allowed them to take place on its premises. He showed on a screen lantern-slides photographed directly from successive parallel sections made on the cadaver, some sections being transverse, some longitudinal, and some sagittal. Several of these pictures exhibited the natural colour of the parts, but what was still more surprising was the direct projection of anatomical specimens on the screen by means of an absolutely new process which seems to be a great improvement in the pictorial illustration of lectures. The specimen being intensely illuminated by the light of acetylene burners reflected by parabolic condensers is placed before an immense photographic lens which throws an image of the specimen on a translucent screen just as a picture is shown on the ground glass of a photographic camera. This takes place in a room at the back of the lecturer's platform, so that when the light is turned down in the lecture-room the pictures can be seen by the whole of the audience. All the details of the preparation being in this way rendered distinctly visible, the parts to which the speaker is referring are touched at the proper time by a pointer held in the hand of an assistant, both the hand and the pointer alike being shown on the screen. By this method a class can follow the successive stages of a surgical operation much better than when witnessing a real operation, because in the latter case the manipulations of the surgeon on the operation table cannot be distinctly seen except by the two or three spectators close at hand. This demonstration by Dr. Doyen was a decided success, and showed that great improvements can now be made in the art of surgical demonstration.

The "Cure" Tax.

A regulation has just been issued laying down the conditions under which special taxes may be levied at mineral water stations. According to this regulation the Communes, after having lodged certain documents at the Conseil d'État, may authorise the levying during a whole or part of the year of a special tax on these stations. The profits will be wholly given to the upkeep and development of thermal or climatic health resorts. The tax is levied on persons who have no domicile in the commune and possess no residence there and the scale may be fixed per person and per day of the visit, or per person independently of the length of stay, and is based upon the style and price of his lodgings. The tax is subject to deductions on account of the ages or number of persons in one and the same family, and varies according to the season of the year. The tax is not levied on any stay under one month, and it will be collected by the agency of lodging-house and hotel keepers.

(FROM OUR OWN CORRESPONDENT.)

Prophylaxis and Therapeutics of Acute Tonsillitis.

Dr. A. Schönemann, professor of oto-rhino-laryngology at the University of Bern, has just published a paper on the Rational Treatment and Prophylaxis of Acute Tonsillitis. He mentions that various observers have recognised that a connexion exists between tonsillitis and other acute infectious diseases, such as polyarthritis (Sahli), endocarditis (Lamnitz), nephritis (Eichhorst), appendicitis (Kretz), and typhoid fever (Lentz). Dr. Schönemann regards the tonsils as lymphatic glands, and is of opinion that inflammation occurring in them is of a secondary nature, not being caused by infection from the mucous membranes of the mouth but being due to primary inflammation in the nose. His clinical observations on patients are corroborated by a series of experiments made by Dr. Lénard on animals and published in the *Archiv für Laryngologie* in 1909. Professor Schönemann's prophylactic and therapeutic treatment consists in the application of 5 to 10 drops of a 2 per cent. solution of protargol or a 5 per cent. solution of collargol once a day. The patient is to spit out the fluid as soon as it reaches the back of the throat. In acute cases he prescribes from 40 to 50 grains of aspirin to be taken on two consecutive days once a day within a quarter of an hour, together with plenty of hot herb tea (Hollunderthee) as an internal antiseptic and sudorific. He is opposed to the use of nasal douches.

Treatment of Infantile Jaundice by Cold Enemata.

At a meeting of the Society of Medical Practitioners held at Zürich on April 20th Dr. Theodore Zangger reported on a simple treatment of infantile jaundice which has given him good results in a series of 20 cases observed during the last 10 years. He orders the administration of cold enemata consisting of about 10 ounces of water at a temperature of 56°, 54°, or 48° F. once or twice a day till the stools become normal, which always takes place in two or three days. If constipation is persistent olive oil and soap lather made with water can be added or the temperature of the water may be

reduced to 40° F. These enemata promote the flow of bile and cause increased muscular contraction of the intestine. In the case of adults the results are not so favourable as in children, and saline aperients are often necessary.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The National League against Malaria.

NOT a day too soon the General Council of the "Lega Nazionale contro Malaria" has held its first meeting in Rome, and the proceedings, necessarily of an initiatory character, gave ample earnest of the solid and thorough-going work expected from it. The president, the veteran Dr. Guido Baccelli, was supported by the flower of the profession, academic and consultant, and his outline of the "plan of campaign" received the cordial adhesion of the speakers who followed. Among these were the Senator Camillo Golgi of Pavia, Professor Grassi of Rome, Professor Queirolo of Pisa, Professor Lustig of Florence, and Dr. Bordoni-Uffreduzzi of Milan—past masters in laboratory work, in clinical experience, or in scientific hygiene. The financial question, and the bestowal of rewards in the form of diplomas, medals, and such like incentives to profitable emulation, evoked a good deal of discussion, but the most interesting proposal, ultimately carried, was that of publishing a "Bollettino della Lega" (organ of the League), under the editorship of Professor Gosio and Professor Gabbi, assisted by Dr. Tropeano and Dr. Montoro. By this means the medical world will have access to the findings of the research department, and also to the conclusions arrived at under such rubrics as the following: 1. Is malaria a misnomer? Or does it connote an atmospheric condition which breeds and maintains the anopheles? 2. Is that condition due to the state of the soil, whether derelict, degenerate, or imperfectly cultivated, as evidenced by the foci of malaria in Italy, on the mainland, and in the islands? 3. Has the systematic exhibition of quinine a really prophylactic efficiency? 4. Has such exhibition, prolonged as a "food," no injurious effect on the vaso-motor system? 5. And finally, What is the scientific etiology, the *causa causans*, of the malady, with a view to its prevention? Answers to these questions have already resulted in quite a "literature" (mainly from Italian contributors), the sifting, appraising, and supplementing of which will be one of the most attractive features of the contemplated "Bollettino." The proceedings, which included a scheme of coöperation with the provincial authorities and with the Italian Red Cross, were brought to a close with a unanimous vote of thanks to Dr. Baccelli.

A Young Medical Martyr.

As I write the news reaches me of the death of Dr. Cesare Zonchello, a Lucchese by parentage, at Gedda on the Red Sea. Dr. Zonchello, who had completed a distinguished academic course, having been, in fact, one of the ablest and most accomplished pupils of Dr. Angelo Celli of Rome, repaired some time ago to the Erythrean littoral, there to study the etiology of pestis bubonica and to experiment on the means of combating it by prevention or cure. The climate, however, combined with the severity of the work to try a constitution not conspicuously robust, and so, when just entering on his thirty-second year, he was taken ill and died, to the poignant regret of his teachers and contemporaries, all of whom had formed the most sanguine anticipations of the success awaiting him.

April 26th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Anti-rabies Institute in Vienna.

A REPORT of the Institute for Anti-rabies Inoculation in Vienna has just been published, dealing with the events of the years 1907 and 1908. Altogether 955 persons received prophylactic or therapeutic inoculations, and 148 persons who had presented themselves received no treatment because they had either been bitten by an animal which was not rabid or because the wound had not bled. Of the 955 inoculated persons 107 had to be excluded from the statistics in consequence of the examination of the respective animals in the pathological laboratory proving negative. The majority of these individuals had been injected only for their personal satisfaction. After deduction of these there remained 846 cases available for clinical observation. 707 were in-patients and 248 were out-patients. Of all the persons under treatment 77 per cent. had been injured by animals which were proved to be suffering from rabies; in 15 per cent. only the symptoms in the living animal, not the post-mortem appearances, had led to the diagnosis of the animal being diseased; and the remainder of the cases were bitten by animals which were to be suspected of having rabies on account of the place they came from. In 1907 there were 2 deaths amongst those who received treatment at the institute, while in 1908 there were 4 fatal cases, or 6 deaths in two years (0·7 per cent. of all cases treated). The number of all cases treated since the establishment of the institute is now 3572, with 26 deaths (0·7 per cent.). One case was very interesting. A man who had been bitten on Nov. 9th was inoculated once on Nov. 29th and died the next day. At the post-mortem examination chronic tuberculosis of the lungs and changes due to chronic alcoholism were found. Portions of his brain, however, when injected into the subdural space of rabbits gave a positive result in three passages. Altogether, 20 persons died from rabies in Austria during the two years: 6 had been inoculated, 13 had had no prophylactic injections, and 1 died during the course of treatment. A comparison between the mortality of the cases treated and not treated is impossible as the number of the latter is unknown.

Unsatisfactory Condition of Various Medical Institutions.

A number of medical institutions have been planned, and the funds for some of them are in the hands of the respective boards, but several of them have not yet been commenced, and with such as are in course of erection the progress is so very slow that the unfavourable remarks made in some medical journals have not been too severe. One of these institutions is the new general hospital, which should have been finished at the end of this year, but at the present rate of building at least another five years will be required for its completion, for even the newly erected clinics for internal medicine and for laryngology have only just been roofed in. The delay is not due to want of money, because the £800,000 devoted for the purpose are at the disposal of the managing board. Another very large charitable institution is the mental sanatorium to be erected in Vienna. The 20,000,000 kronen (or about £1,000,000 sterling) were bequeathed by the late Baron Rothschild on the understanding that an institution should be erected for the treatment of sufferers from nervous disorders who cannot find help anywhere else. The committee have found a suitable site for the building, but prejudices, racial, religious, or of some other kind, have interposed an unsurmountable obstacle. A new institute for the teaching of physical laws and phenomena is an urgent necessity in this city. The present institute for this purpose is absolutely inadequate. It would be a veritable deathtrap if an accident should happen during experiments, so that the professor very wisely abstains from making them. The students have to be asked to come to the lectures not all at once but only in turns. A promise was obtained from the Government that a new institute would be ready by 1910, but it is not yet even begun. The radium institute, a gift by a wealthy private individual, is ready, but it cannot be made use of until an adequate physical institute is provided.

Celebrations in Honour of Professor Königstein.

A few days ago Professor Königstein, one of our best known ophthalmologists, celebrated the sixtieth anniversary of his birthday, and his numerous friends took the opportunity of expressing the respect and esteem which they have for him. Professor Königstein, who is also President of an important Austrian medical society, was the recipient of many honours, and a banquet at which he was entertained will be a memorable event in the social life of this city. He has had a principal share in establishing many useful medical organisations, such as the Medical Sickness Insurance Society, the Medical Protection Society, and some others, the main object of which is to assist practitioners who have to work hard for their living. An orchestra composed of medical men (Aerzte-Orchester), the creation of which is in a large

degree owing to his efforts, played musical selections at the banquet, thereby proving that the medical profession includes many members who may with justice claim possession of the artistic faculty.

A Case of Communication between the Trachea and the Œsophagus.

At a recent meeting of the Gesellschaft der Aerzte Dr. Schwarz showed X-ray photographs and plates of a remarkable case. The patient was a man, aged 69 years, who suffered from difficulty in swallowing and a diagnosis of carcinoma of the œsophagus was made. While under examination by means of the X rays it was seen that a solution of bismuth went down, not into the stomach, but into the lungs, with the result that on the screen a perfect image of the bronchial tree with all its branches came into view, except in the uppermost parts of the upper lobes of the lungs. The liquid had, in fact, been "swallowed" into the respiratory passages, so that the man breathed now only with a small part of his lung, and nevertheless did not experience any discomfort. Dr. Schwarz said that this extraordinary condition could not be easily explained. The man never complained of cough or any bronchial trouble, and although he must have swallowed all liquid, such as tea, milk, and coffee, into the lung for a period of at least three weeks, there never was any symptom of the pneumonia which was to be expected when liquids of such a nature came in contact with the alveoli. In the œsophagus a cauliflower-shaped tumour was found just at the level of the bifurcation in the trachea, and by means of tracheoscopy Dr. Kahler, in Professor Chiari's clinic, could demonstrate the point of communication between the trachea and the œsophagus, distant 24 centimetres (10 inches) from the teeth. A similar case was observed by Dr. Horner in the Vienna General Hospital five years ago, but at that time the technique of X ray examination was not so far advanced as at present, and it was impossible to obtain convincing plates for demonstration. In both cases it was only liquids which made their way into the lung, semi-solid food being swallowed into the stomach in the ordinary manner.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The Propagation of Tuberculosis among Children.

Professor Baginski, the Director of the Kaiser Friedrich Hospital at Berlin, gave a very interesting lecture on the above subject in the Imperial Medical Society Hall of Constantinople. In the course of his remarks he said that if there was a malady that was spread universally in all parts of the globe, causing enormous ravages and costing great sums of money to different Governments, it was tuberculosis. In case of an epidemic of, say, plague or cholera, the necessary measures of precaution, prevention, and cure are taken temporarily for a certain definite period of time, whereas in tuberculosis the strain, the struggle, the suffering, and the expense are constantly there year in and year out. Tuberculosis makes great ravages at every age, mainly among children. Of late the mortality here from tuberculosis has diminished, owing to hygienic precautions, but even with all that the mortality among children is terrible. In 1919 children inoculated with tuberculin there were 435 positive reactions, although in appearance these children looked perfectly healthy.

An Epidemic of Dengue Fever.

It is reported from Jerusalem that a severe epidemic of dengue fever has been spreading in an alarming way along the Syrian and Palestine coasts. Thousands of people, old and young, poor and rich alike, were stricken by the disease. It is mentioned in the Turkish papers that dengue has something like 50 different appellations and that in the named places the severest known epidemics were those of the years 1886, 1896, and 1909. It is believed that in 1886 the epidemic was carried to Smyrna by cargoes of old rags brought annually in large quantities to that city from Palestine, Syria, and Cyprus. The Arabs call the fever "abou rukabah," which means "the father of the knee," as, of all joints, that of the knee experiences in dengue the most excruciating pain. A peculiar characteristic of the disease is said to be loss of memory, so that patients very frequently cannot remember familiar names and words. Dr. Lorch, who lived in Palestine for over 30 years, holds that people who have suffered from dengue fever acquire a certain predisposition to such infectious diseases as typhoid fever, cholera, and malaria.

The Attitude of Turkish Women to Medical Men.

The attitude of the hanoums to medical practitioners has changed much of recent years. Two or three decades ago no Turkish woman would ever have submitted to a physical examination by a doctor. All he could have persuaded her to do would be to show him her tongue through a rent in the *yashmak* or let him touch her pulse from behind a heavy curtain and in presence, of course, of an Argus-eyed eunuch or old female slave. Any attempt to apply a stethoscope to the chest would have been spurned as an impertinent presumption of Western "barbarism." No matter however severe the illness, the medical man could not go beyond certain strict limits of Islamitic usage and traditional custom. Even in cases of imminent danger to life these scanty limits were never allowed to be overstepped, and the belief in the incantations of a priest and the house remedies of old, ignorant, and superstitious women held unlimited sway and was always greater than the faith in the efficacy of medical skill and science. This is now changing, and changing rapidly. There are, of course, still many exceptions where antiquated views and conceptions are fanatically adhered to and practised, but these become rarer and rarer with each advancing year. Many Turkish women will now, when ill, voluntarily call on a medical practitioner, and never hesitate to submit themselves to a thorough physical examination. The general public opinion on these matters among the Turks is fast altering for the better and only in very rare cases is there now any difficulty at all raised as to letting the hanoum submit to an examination with stethoscope or other instrument.

A Jewish Hospital at Jaffa.

A movement has been started to create a small Jewish hospital at Jaffa. I understand that already 1500 francs have been collected for that purpose and that the interest in the undertaking is growing. A society consisting of Jewish ladies has in the meantime opened a special hall for the treatment of women in confinement. A certificated nurse has been sent from Europe to Jaffa.

Typhoid Fever at Koutahia.

An epidemic of typhoid fever still continues its ravages at Koutahia (Asia Minor). It has been decided to send there a medical practitioner as well as £T300 to combat the spreading of the disease.

April 30th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

National Campaign on Oral Hygiene.

A NATIONAL campaign on oral hygiene was opened in Cleveland, Ohio, on March 18th, under the auspices of a committee of the National Dental Association. At the instance of President Taft, Assistant-Surgeon Wilie of the Public Health Service was detailed to attend the meeting in a representative capacity. Surgeon Wilie explained the objects and methods of the committee on oral hygiene of the National Dental Association as being to secure the appointment of district dental inspectors and to provide for widespread dental education on oral hygiene in the public schools of the country. This movement had its origin in the meeting of the association in 1898, but owing to lack of proper appreciation of the importance of the subject the reform made little progress. The State of Massachusetts has taken cognizance of the importance of this work, and popular lectures on dental hygiene and prophylaxis are permitted in some of the public schools under the supervision of the respective boards of education. Several cities established clinics for the dental examination of the poor, but there was no widespread appreciation of the importance of the subject until the meeting of the National Dental Association in 1908, when one session was devoted to oral hygiene. This discussion aroused great enthusiasm and from that time the movement has taken on a national character. It is now proposed, under the auspices of the

National Association, to enter upon a campaign of education which shall extend to every State and city in the Union.

The Hospital Admission-rate for Tuberculosis among Merchant Seamen during the Past 20 Years.

Surgeon Young, of the Public Health Service, has made an elaborate report on the results of the establishment of a sanatorium for seamen affected with tuberculosis. The sanatorium was opened at Fort Stanton, New Mexico, in 1897, a location at a high altitude and in an arid district. The controlling reason for the establishment of the sanatorium was the fact that under conditions as they then existed patients who got well enough to demand their discharges went at once on board ship and spread the infection among their shipmates. The comparison is made between the out- and in-patients ten years before and ten years after the opening of the sanatorium. In 1889, ten years before the opening of the sanatorium, the out-patients numbered 543, and in 1908, ten years after the opening, they numbered 157; in 1889 the number of hospital admissions was 437, and in 1908 they were 342; the total of the two classes was in the first period 980 and in the last 499. It appears that the total admissions in 1908 are only 46·7 per cent. of what they were the year before the segregation began—viz., in 1896, when the total was 1061. Surgeon Young does not claim that this reduction is entirely due to the present policy, but he believes that it has had a notable influence in producing this result.

"Tuberculosis Sunday."

The campaign against tuberculosis has reached another stage in this country. On "Tuberculosis Sunday" (April 24th) the clergymen of every denomination are urged to devote one discourse to the subject of tuberculosis. The suggestion has been received with the greatest enthusiasm, and there will be a general concurrence in the proposed method of educating the public in regard to the nature and method of prevention of the great white plague.

The Relation of the University to the Medical School.

President Schurman, of Cornell University, recently gave an address on the relation of the university to the medical school before the Joint Conference of the Council on Medical Education and the Committee on Medical Education of the American Medical Association. The address was important chiefly because it clearly pointed out the difference between the medical schools of the country under private control and management, of which there are still a large number, and those that are under the direction of university faculties. The private schools, he contended, must necessarily become commercial in their management, as they are established in the interest of a few individuals, and every device is resorted to to increase the number of students. The most disreputable feature of these schools is the low standard of qualification which they maintain in order to attract the masses of unfit students. "The personal profit of individuals," said the President, "has been the most powerful and prolific motive for the multiplication of medical colleges, as it has also been the most pernicious." Against these schools the profession has struggled for years in vain efforts to raise the standard of education. But a new era is dawning, and the general spirit of the age, as well as higher ideals of professional education, are, in the opinion of the President, working against these commercial medical schools. The first service which, in his opinion, the university renders to the medical school is to discourage its organisation or continuance without ample endowment. Though this service is negative, it is fundamental and vital. The second aid of the university is in determining the grade of preliminary education of students applying for admission. The third method of assistance of the medical department by the university is in securing a high class of teachers. This address will prove a powerful agency in the complete elimination of the private medical schools.

The Failure of the Emmanuel Method in California.

The much talked of method of treating nervous affections popularly known as the "Emmanuel treatment," the name being derived from the church of that name in Boston where the system was first promulgated, has proved a complete failure in California. This is the testimony of the Bishop of California, under whose direction a hospital was established for the purpose of testing its efficacy. The physician appointed to carry out the treatment in the hospital has resigned his position, declaring that the system was a failure, and the bishop has closed the institution. The physician made a public statement of the utter failure of the method, alleging that whatever may be the results of treatment by the Emmanuel system in Boston, it was evidently not adapted to the climate and people of California. The readers of THE LANCET will remember that the system was described in this correspondence as hypnotic suggestions by a priest. It was first published by the rector of the Emmanuel Church of Boston, and was adopted and attempted in several Episcopal churches in different parts of the country. Several prominent physicians of Boston endorsed the method, and to the extent of their influence gave considerable popularity to the system.

Illegal Sale of Cocaine in the Cities.

The traffic in cocaine has increased to a dangerous extent in the cities of the United States. It has been found that the drug is not only distributed to habitual users, but has even been given to public school children on the street. In the city of Philadelphia a crusade against the illegal sale of cocaine has been inaugurated under the direction of a member of the State Pharmaceutical Society. Several physicians have been arrested and also more than a score of retail druggists. On examination of the reports of wholesale dealers as to the amount of cocaine sold it was found that one had sold 1900 ounces of the drug in one month, and another's sales had amounted to 1400 ounces in the same time. This rate of sale would make their yearly sales between 15,000 and 20,000 ounces, which amount it is claimed is entirely too high for the quantity of the drug which can be disposed of legally. The crusade has gone so far as to cause the arrest of a United States inspector of drugs on the charge of unlawfully selling cocaine, and it is stated that there are several prominent men under suspicion of illegally dealing in the drug.

A National Secretary of Public Health.

The efforts to secure legislation from Congress creating a National Public Health Department have recently taken a new form. Hitherto the measure approved by the President and the larger number of medical societies has been to group together all the branches of the public service which have duties to perform relating to quarantine, life-saving, and the control and prevention of epidemics in the existing Bureau of Public Health and Marine Hospital Service. Recently an organisation, known as the "Committee of One Hundred," has introduced a Bill into Congress establishing a Department of Public Health, the chief officer of which is a "secretary of public health, who shall be appointed by the President a Cabinet Officer ..... with like tenure of office of other Cabinet Officers." The general provisions of the two measures are not unlike. It is unfortunate that the promoters of this most desirable legislation are now to be divided, for instead of devoting their united energies to a single measure they are quite likely to prevent any action of Congress by their own dissensions.

More Intimate Relations of Colleges and Hospitals.

The most important and least supplied feature in our system of medical education is actual service of the student in hospital wards. Of the two or three hundred medical graduates from the three schools of New York annually not more than from 10 to 15 are able to obtain appointments in the resident staffs of the hospitals. For the few vacancies which are open to the students on their graduation there are often from 50 to 60 applicants in competitive examination for each place. Of course, the student who passes the best technical examination wins the place, while the rest begin practice without the preparation which the hospital service of even a few months would have given them. New York has a total of 76 general and special hospitals, with 11,467 beds, but only 10 or 12 hospitals allow competition for positions on the resident staffs. If a scheme were devised by which medical students could fill the positions of *attendants* in the hospitals as well as on the regular medical staff, every graduate would have an opportunity to actually practise his profession under the immediate instruction of competent teachers. The first step towards a more intimate relation of the colleges and hospitals was taken recently when the College of Physicians and Surgeons added the physicians and surgeons of Mount Sinai Hospital

to its corps of teachers. This alliance will open to the students of the College one of the largest and best equipped hospitals in this city, and may be the beginning of a utilisation of the great number of hospitals for the more complete education of students.

April 24th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE plague returns for the United Provinces for the week ending March 26th show a decided decrease on the figures for the previous week, the total deaths being 6961, as against 9211. Azamgarh district still reports over 1000 deaths, and the mortality in the Ballia district runs to 788. Other severely affected areas are: Unao district 635 deaths, Ghazipur district 580, Gorakhpore district 481, Mainpuri district 359, and Bara Banki district 295. Five other districts report over 200 deaths in the week. The disposal of the dead continues to be a subject of inquiry in Calcutta in connexion with the suppression of plague, and considerable attention has lately been paid to the conditions prevailing at the burning ghats and burial grounds to the south of Calcutta city. It is satisfactory to notice that a recent tendency to bring a large number of the suburban dead into Calcutta for disposal has not been allowed to flag, for during last year the total so brought in was 3321, of which 1891 were cremated and the rest buried. The year has also furnished unmistakeable proof of the greater incidence of plague amongst the population living in huts, since it is estimated that 1 in 301 of the population living in *kutcha* or mud-built huts was attacked, whereas the ratio was only 1 in 433 for those living in *pucca* or stone-built dwellings. The cases in huts formed 68·4 per cent. of the whole, while the population living in huts is set down as less than 60 per cent. of the whole population. Attention is again drawn, on the year's work, to the preponderance of "single cases," and out of 2155 cases reported it is significant that not less than 1958 were single, so that the case incidence works out at not more than 1·1 per infected dwelling. These figures, while furnishing very strong proof against the conveying, in the majority of the cases, of the infection from one dwelling to another, also seem to indicate that the infection does not remain in the dwelling. The occurrence of a second case after an interval in the same dwelling also appears to be quite uncommon. It is evident, however, that the difficulties in discovering "contact" cases must not lightly be passed over. Information is consistently withheld, and owing to the undesirability of making searches inquiries are often fruitless. Regrettable as it is, it is therefore comprehensible that the hospital cases should have showed a mortality of 84·2 per cent., a distinctly higher figure, that is, than in 1908, and that during last year the mortality of cases seen alive in the early stages of the disease and the mortality in general should also have been higher.

Malaria in Tea Gardens.

A resolution has been issued by the Government of Eastern Bengal and Assam regarding the prevalence of malarial fevers among those working in the tea gardens of Jalpaiguri and Duars, which recently engaged the serious attention of the Lieutenant-Governor. As the information available on the subject is incomplete, the Lieutenant-Governor decided to appoint a representative committee to inquire into the sanitary and economic conditions under which tea-garden coolies live and to advise the Government what remedial measures, if any, should be undertaken. The committee assembled at Jalpaiguri on April 4th and consisted of the Hon. Mr. F. J. Monahan, President, Mr. Scroope, Mr. Chaplin, Lieutenant-Colonel F. R. Ozzard, I.M.S., and Major A. Leventon, I.M.S. The Lieutenant-Governor states he is confident that the Indian Tea Association and the planting community generally will assist the committee and supply such information, facts, and statistics relating either to the Duars generally or individual tea gardens as may be required.

The Campaign against Disease.

Lieutenant-Colonel C. C. Manifold, I.M.S., officiating Inspector-General of Civil Hospitals in the United Provinces, at a recent meeting of the United Provinces Legislative Council, during a debate on the financial statement of the provinces, drew attention to the expenditure on the prevention of disease. The fact that this was becoming more and more a feature of the medical budget must, he thought, force itself upon the attention of honourable members. When they realised that most of the diseases which had hitherto caused so much havoc in the United Provinces need not even exist if the means for their prevention were thoroughly carried out and employed in time, expenditure on these lines would, he thought, commend itself to all. Plague had been combated on scientific lines for some years past, and though there had been some recrudescence of this disease, yet they might reasonably hope after the good results obtained last year by the measures taken that the present outburst was only a flicker from the dying embers of the epidemic. Under the sanitation grant one of the most important new features was the employment of a special officer in the investigation of malaria, which in the United Provinces usually caused a greater mortality than other much more dreaded epidemic diseases, and yet it was one which modern science had shown to be a preventable disease. In scientifically studying its special conditions of existence in the United Provinces they were throwing out their scouts to prepare the way for a great attack upon it in the immediate future. The travelling dispensaries were a new feature, which would bring the greatest boon to the door of the agriculturist in remote places and would ensure that medicines, especially quinine, reached him. In devoting a sum to raising the pay of hospital assistants, they were recognising the services of a very hard-worked and deserving body of men, who formed the main body and should be the backbone of the medical department. Their pay had now been brought up to the same level as that of the sister branches. Lieutenant-Colonel Manifold subsequently mentioned that the Medical College at Lucknow would soon be nearing completion, and a system of education was being evolved for it which would select and adopt the best form of modern institutions already in existence.

The Grant Medical College.

H.E. the Governor of Bombay on March 30th performed a series of ceremonies at the Grant Medical College in the compound of the Sir Jamsetji Jeejeebhoy Hospital. The occasion was the annual prize-giving to successful students of the Medical College, and the opportunity was taken of His Excellency's presence to have the buildings erected in connexion with the college and hospital formally declared open. In so doing the Governor said he could not help noticing that in India the obtaining of a degree of any kind was regarded too often as the primary object which, if attained, should open the door to lucrative employment without expenditure of too great exertion, and if such employment was not forthcoming there was a tendency to throw the blame on the Government. He believed that a degree was only a guarantee of a certain minimum of attainment and that the real work of life began afterwards. In India, as in all other countries, a graduate must show what he had in him and must win success, not by passing examinations only, but by actual work done. Competition in the medical profession was keen in Bombay, and not, as in other countries, between qualified practitioners, but between qualified and unqualified. There was, therefore, all the more reason for students to be able to demonstrate the infinite superiority of skilled to unskilled medical treatment.

April 9th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Medical Evidence.

A JUDGMENT has just been delivered in the High Court of Australia on an appeal from a court below. The plaintiff brought an action for the recovery of an insurance policy on the life of his mother. The defendant was the National Mutual Life Association, and the claim was disputed on the ground that the proponent had not disclosed the true state of her health at the time of proposal. The association sought to uphold its defence by the evidence of Mr. E. T. Thring, F.R.C.S. Eng., of Sydney, but his evidence was rejected by Mr. Justice Hodges on the ground that under Section 55 of

the Victorian Evidence Act the doctor had not obtained the consent of his patient to make any disclosure of facts observed by him or disclosed to him. Judgment was given for the plaintiff in the court below, and against this the defendant appealed. An appeal had already been refused by the State Full Court. The Chief Justice of the High Court said the appellants sought to show that the existence of the complaint causing death must have been antecedent to the date of the proposal. Section 55 of Evidence Act (Victoria) provided that—

> No physician or surgeon shall without the consent of his patient divulge in any civil suit action or proceeding (unless the sanity of the patient be the matter in dispute) any information which he may have acquired in attending the patient and which was necessary to enable him to prescribe or act for the patient.

His honour thought the word "necessary" must be construed in a wide sense so as to include any information which was or was likely to be relevant in determining the proper treatment of the patient. The question to be solved depended upon the construction to be given to the terms "information acquired" "in attending" and "to enable him to prescribe or act." The appellants, while not disputing that the words "information acquired" were capable of the meaning put on them by the State Supreme Court and by most of the American courts, contended that it was not the only nor the most probable meaning. They pointed out that at common law communications between a patient and his medical adviser were entirely unprivileged, and that this state of the law had been often animadverted upon by learned judges. It did not appear, however, that in any of the cases referred to the confidence which was necessarily violated in the witness-box related to any physical fact disclosable by ocular observation or even to the statement as to the health of the patient. The section plainly protected "information" which was relevant to health. Giving the fullest weight to all the arguments for appellants on the word "information," a further difficulty was raised by the word "acquired," which suggested sources of information not limited to communications, verbal or demonstrative, from the patient. He (his honour) was reluctantly compelled to the conclusion that he could not see any satisfactory ground for so limiting its meaning. What, then, was the limitation imposed by the words "in attending the patient"? He did not think that the mere fact that a physician or surgeon prescribed for or operated on a human being necessarily constituted that human being his patient within the meaning of the section. In his opinion the words connoted a period co-extensive with the continuance of the relation of personal confidence which might be assumed to exist between the physician and patient. Whether that relation ever existed, or, having existed, still continued at any particular moment, was in every case a question of fact. In the case of a person who undergoes an operation at a public hospital when the necessity and nature of the operation have already been decided upon, he did not think that the person operated upon was necessarily, within the meaning of the section, the patient of the surgeon who there saw him for the first time. Such a surgeon was, therefore, not necessarily prohibited from divulging what he saw in the course of the operation. He thought that it was very likely Mr. Thring could have given some evidence which would have been admissible under the statute; but, on the whole, he did not think that the attention of the learned judge was drawn to any distinction between facts discovered by observation, and not necessary to enable the witness to prescribe or operate, and facts which were necessary for that purpose. Possibly the evidence would still have been rejected, even if that distinction had been made, since the objection taken was assumed to cover the whole ground. In view of the facts, and the fact that evidence on the point of probability had already been given on both sides, he found himself unable to say that he thought any substantial wrong or miscarriage was occasioned by reason of the rejection of the evidence. He was not able to import a limitation of the prohibition to the lifetime of the patient; and even if executors could give consent—a point on which he reserved his opinion—it was not given in the present case. Mr. Justice Barton, Mr. Justice O'Connor, Mr. Justice Isaacs, and Mr. Justice Higgins also delivered separate judgments, and the court unanimously came to the conclusion that the appeal should be dismissed, with costs.

Children's Hospital, Sydney.

The thirtieth annual meeting of the supporters of the Royal Alexandra Hospital for Children, Sydney, was held on March 17th, under the presidency of Mr. C. P. B. Clubbe. During the year a nurses' home had been opened by Lady Dudley. The number of in-patients had been 1721 for the year, with a mortality of all cases of 10·7. In the outdoor department 13,436 new cases were treated, and attendances totalled 46,381.

New Medical School.

The arrangements for admitting St. Vincent's Hospital as a recognised clinical school in the University of Melbourne have been completed, and the new pathological wing was opened by Sir John Madden on March 20th. It is generally admitted that for its size (about 120 beds) St. Vincent's is equal to any modern hospital in any part of the world for equipment and excellence of design.

Curious Action.

An action for damages was heard before Mr. Justice Pring in Sydney which presents some unusual features. The plaintiff was a pupil at the Marrickville State School, and was one of a class in elementary chemistry being taught by the headmaster. One day, in commencing a chemistry lesson, the headmaster called to another boy to bring a tumbler from his room. This vessel contained a small quantity of brownish liquid, and the boy, thinking it was dirty water, threw it out. The liquid proved to be diluted sulphuric acid, some of which struck the plaintiff in the right eye, causing what was alleged to be permanent injury. It was submitted that the headmaster was guilty of negligence in not warning his messenger of the dangerous nature of the contents of the tumbler. The jury returned damages against the master for £431 0*s.* 9*d.* During the hearing the question of non-liability of the Government in the case of a school teacher was raised, and Mr. Justice Pring, while regarding it as important, preferred to leave the case to a jury. A stay of proceedings was granted till next term.

Provision for Consumptives.

The Victorian Government intends to proceed with a scheme for providing an institution for the relief of advanced cases of consumption. At a recent conference of municipalities Dr. B. Burnett Ham explained that although some municipalities wished to make their own provision, the proposal to have one hospital for advanced cases was to be commended for its financial economy. The Government had spent £7410 during the last two years on the existing sanatoriums at Greenvale, Amherst, and Daylesford. These were for incipient cases. The advanced cases were the foci of infection. If any progress was to be made such cases would have to be gathered up and isolated. He stated that he was prepared to compel any municipality to join in the scheme for financing the proposed new hospital, and if within three months there were any who still objected he would know what to do. A vote of thanks was accorded to Dr. Ham for his assistance to the conference.

Miners' Phthisis.

A conference was called by the Mayor of Bendigo to consider the above question. Mr. C. B. Gaffney advocated the following points: (1) that miners should be put under the control of the Board of Public Health; (2) insistence of proper ventilation of mines; (3) absolute insistence on spraying to keep down dust; (4) inspection of men as to fitness for work; and (5) proper attention to dwellings. Mr. O. Penfold recommended (1) early reporting of infection; (2) better conditions in mines; (3) instruction of children; and (4) sanatoriums. Dr. W. Summons said that absolute prevention of dust was the most important thing to bring about. More inspectors were required. The only person that could be dealt with above was the infected miner. Institutional treatment should be established. Mr. H. E. Jackson wanted a distinction drawn between tuberculosis and "miners' disease." The latter should be regarded as an industrial disease, and if treated as such much benefit would result. Resolutions were carried advocating the provision of spraying apparatus and more inspectors, and also the establishment of a sanatorium, and an executive committee was appointed to further the matter.

Talbot Epileptic Colony.

The annual meeting in connexion with this colony

was presided over by Sir T. Gibson Carmichael, Governor of Victoria. It was stated that the number of colonists was 51, the sexes being almost equally divided. The honorary medical officer said that the greatly improved condition of many of the inmates justified the existence of the institution, and he urged the need of a children's ward. Dr. J. W. Y. Fishbourne said it was estimated that there were 5000 epileptic children in the State for whom nothing had been done. Public subscriptions had only amounted to £189. The colony has been three years in existence.

March 22nd.

Obituary.

STEWART LOCKIE, M.D. EDIN., L.R.C.S. EDIN.,

CONSULTING PHYSICIAN TO CUMBERLAND INFIRMARY.

WE regret to record the death of Dr. Stewart Lockie, which took place at his residence at Stanwix on April 18th. Dr. Lockie was born in London in the year 1836, and while still at an early age his parents, who were of Scottish descent, returned to Berwickshire. At Earlston, and afterwards at Kelso Grammar School, Dr. Lockie received his early education, and on leaving the latter institution he was apprenticed to a medical man at Kelso. In 1854 he entered the University of Edinburgh, where he came under the influence of Simpson, Goodsir, Christison, and Syme. It was while at the University that he made the acquaintance of Sir Thomas Grainger Stewart, an acquaintance which ripened into a lasting friendship. In 1858 he took the M.D. degree of his University and also became a Licentiate of the Royal College of Surgeons of Edinburgh. Immediately afterwards he was appointed house surgeon to the Carlisle Dispensary, which position he held for three years. While there he was much struck with the ignorance of the people with whom he came into contact, and in consequence opened night classes in the central schools, where for more than a year he taught the "three r's" to the working men of the city. In 1861 he commenced private practice and four years later again renewed his connexion with the dispensary by becoming honorary visiting surgeon. Subsequently he became physician to the Cumberland Infirmary, the welfare of which institution was his constant care. Previous to 1873 the wards were small and overcrowded, and the building could scarcely accommodate 40 persons, although it was nominally intended for 50. Under Dr. Lockie's supervision the buildings were enlarged, and as a consequence additions were made to the medical and the nursing staffs. In 1897 Dr. Lockie resigned from the office of honorary physician, and the governors of the institution, in order to mark their appreciation of his services, elected him consulting physician. In 1901, when he retired from active practice, he was elected a vice-president and received many tokens of esteem from his professional brethren and his patients. Perhaps no better proof could be afforded of the esteem in which he was held by his colleagues than the dinner given on the occasion of his resignation of the post of physician to the infirmary. Many of his colleagues came long distances to do honour to their former chief—"dear old Lockie," as he was affectionately called. An original member of the Cumberland and Westmorland Branch of the British Medical Association on its foundation in 1868, he acted for two years as secretary of the branch, and in 1877 was elected its President. When in 1896 the British Medical Association held its annual meeting in Carlisle Dr. Lockie acted as Vice-President of the Section of Medicine.

A man of keen sympathy with sickness and suffering, and with a high conception of his duties and responsibilities, he earned for himself a name which will long remain a household word, not only in Carlisle, but in the districts for miles around. In private life he was gentle and unassuming, and his influence with young men, especially those in his own profession, was very great. The remains of Dr. Lockie were interred on April 21st by the side of those of his wife in Carlisle Cemetery, when a large gathering of medical men from the surrounding districts attended the funeral service.

PETER YOUNG, L.R.C.S. EDIN.

THE death occurred at his residence at Dundee, on April 19th, of Mr. Peter Young, who for many years occupied a leading position in the medical profession in Dundee. Mr. Young, who had attained the age of 84 years, lived an active life, and many will learn with a shock of his death. He was born in Balnaguard, Strathtay, in 1827. He became L.R.C.S. Edin. in 1856 and for some time thereafter assisted a medical practitioner in the North of England. His health giving way, however, he returned home again for a brief rest. Beginning work again he started practice at Erroll, in the Carse of Gowrie, where he remained for some years. He subsequently, in 1860, removed to Dundee, where he continued to practise until a few years ago. By his professional skill and cheery disposition he soon built up an extensive practice, chiefly amongst the middle and working classes. His popularity increased as the years went on, and in the city generally he was held in high esteem. He was perhaps one of very few in Dundee who could not only read and write but speak the Gaelic language, and he was chief of the Dundee Highland Society when the Mod was held there under the presidency of the Duke of Argyll. He also took a keen interest in public affairs and for some years was a member of the old parochial board. Religious, philanthropic, and temperance organisations also received his support and sympathy, and his labours in that direction indicated his desire to do what he could for the moral and material betterment of the community. He was a Free Churchman since the disruption, and was ordained to the eldership in 1850, repeatedly attending the general assembly as a representative elder.

Mr. Young retired from practice a few years ago and was in the enjoyment of excellent health up to a few days before his death. He was predeceased by Mrs. Young about five years ago, but is survived by a family of two sons and one daughter. One of the former is Mr. Charles Young, who carries on the practice in Dundee, and the other is Mr. J. McLauchlan Young, lecturer on veterinary hygiene in the Aberdeen and North of Scotland College of Agriculture.

ALONZO HENRY STOCKER, M.D. ST. AND, M.R.C P. LOND., M.R.C.S. ENG., L.S.A.

Dr. Alonzo Henry Stocker died on April 24th at his residence, Craigweil, Aldwick, Sussex, in his eighty-first year. Dr. Stocker, who was for many years one of the best known specialists in lunacy, received his professional education at the London Hospital, where, as a student, he won the gold medals for surgery, midwifery, chemistry, anatomy and physiology, and materia medica and therapeutics; also the silver medals (senior prize) for botany and forensic medicine. He was awarded the first honorary certificate for medicine and the surgical gold medal presented by the governors of the London Hospital for attention to the patients of that institution. He also won the second prize in botany awarded by the Apothecaries' Society of London. In 1851 he took the diploma of L.S.A., and in the following year that of M.R.C.S. Eng.; in 1855 he graduated as M.D. of the University of St. Andrews, and in 1860 he was admitted M.R.C.P. Lond. In 1852, at the age of 22 years, he became medical superintendent of Grove Hall Asylum, Bow, in the east of London, at that time the largest private lunatic asylum in the country. Later he became proprietor of two other asylums in London—namely, Peckham House, Peckham, S.E., and Northumberland House, Finsbury Park, N. He was a life governor of Bethlem Royal Hospital and a member of many medical societies. He retired from active work about ten years ago.

BRIGHTON SCHOOL CANTEENS.—The work of the school canteens at Brighton has justified their existence. This is shown by the report which the school medical inspector, Dr. J. Lambert, has just presented to the education committee. During the year ended March 31st last only 5 per cent. of the children on the books of the elementary schools of the town were fed, against 8 per cent. in the previous 12 months; and of 148 children who were recommended for meals on medical grounds 23 per cent. were brought over the average weight for a given height and are no longer eligible for free meals on medical grounds. The total sum expended on food during the year amounted to £216. The work of the canteens has shown unmistakably how the physical and psychical sides of the young are intimately connected. It is not only cruel but futile to attempt to teach the underfed or the starving.

Medical News.

UNIVERSITY OF OXFORD: POST-GRADUATE COURSE ON OPHTHALMOLOGY: THE OPHTHALMOLOGICAL CONGRESS.—The annual course on ophthalmology has been arranged from June 27th to July 8th. The main idea of the course is to demonstrate (on actual patients as far as possible) the whole range of ophthalmology, in order to make the reading of a text-book more profitable than can be the case when relying merely on pictures. The first part will be mainly devoted to demonstrating the practical examination of eye patients, the use of the ophthalmoscope, and the work of refraction. During the second part the work will be more specialised, and the lectures delivered by various ophthalmic surgeons.—The ophthalmological congress this year will meet on Wednesday evening, July 20th. 150 rooms will be available in Keble College for the first applicants, and will be allotted in order of application. About 120 names have already been received as foundation and original members of the congress, and Mr. Sydney Stephenson, honorary secretary, 33, Welbeck-street, London, W., will receive further names of original members until June 24th. There is no annual subscription, but half a guinea entrance fee will be charged and half a guinea on each occasion that a member shall attend the congress. The programme of the congress will be sent out later to those who have sent in their names for membership. The special features of the congress will be operations for cataract and glaucoma. Operations will be performed by, amongst others, Professor Lagrange (Bordeaux), Professor Holth (Christiania), Professor Heine (Kiel), and Colonel H. Herbert (Nottingham), who will each perform his operation for glaucoma. Sir Anderson Critchett will operate for cataract, and Major H. A. J. Gidney, I.M.S., will perform the intracapsular cataract extraction practised by Major H. Smith. It is not proposed to have papers and discussions, but a series of demonstrations and exhibitions. Anyone who would care to show something, give a demonstration, or perform some operation should apply to Mr. R. W. Doyne, Margaret Ogilvie Reader in Ophthalmology, who will make all arrangements for the purpose. In the case of an operation the surgeon should bring his own patient, who will be accommodated in the hospital. Any further information may be obtained from Mr. Doyne, 30, Cavendish-square, London, W.

THE BRUSSELS MEDICAL GRADUATES' ASSOCIATION.—An extra dinner of this association was held at the Trocadéro Restaurant on April 29th, and was attended by 33 members and their guests, among those present being the President (Dr. R. Paramore), Dr. W. S. A. Griffith, Dr. C. Ogle, Dr. Wickham, and the honorary secretary, Dr. Arthur Haydon. The President, in giving the toast of "The Visitors," referred to the work which had been carried out by Dr. Griffith when President of the Medical Defence Union, and also coupled the names of Dr. Ogle and Dr. Wickham with the toast. These three gentlemen having responded, "The Brussels Medical Graduates Association" was proposed by Dr. Ogle. In reply Dr. Haydon said that this dinner had been organised in order to consider plans for holding the annual meeting and dinner this year at Brussels in the Brussels Exhibition of 1910, probably in August. There were now about 800 British graduates of the University of Brussels in all parts of the world, and the number was steadily increasing, for the number of colonial and foreign members was growing rapidly. They were becoming a very strong body. He thought that an annual meeting in Brussels would draw the attention of the King of the Belgians to the existence of the association, and the work it was doing for the University of Brussels, while the fact that the Queen of the Belgians was herself a lady doctor might lead their Majesties to become patrons of the association. He said that as a result of a visit to Brussels last year to advocate certain reforms with regard to the admission of candidates for the degree all the proposals made had since been carried out by the University. Dr. Wickham proposed the health of the President. The President suitably responded. A programme of music was rendered by Miss Dorothy Wiley (soprano), Miss Madalaine Marshall (pianist), Dr. Arthur Haydon (solo violin), and Dr. Maughan (pianist).

Lord Howard de Walden will preside at a Festival Dinner in November next to celebrate the 125th anniversary of the St. Marylebone General Dispensary, commonly called the "Welbeck Dispensary." Opportunity will be taken to create a fund to meet pressing needs and to relieve the charity of the burden of an old-standing rebuilding debt. The last dinner was held at the Centenary celebration 25 years ago.

RESIGNATION OF A MEDICAL OFFICER.—At a meeting of the Lincoln city council on May 3rd the health committee reported that it had received a letter from Dr. C. Harrison resigning his appointment as medical officer, which he had held for 44 years, and it had accepted the same and placed on record its very great appreciation of the industrious and most capable service rendered by him to the city. The committee recommended that Dr. Harrison be appointed consulting medical and sanitary adviser to the corporation at a salary of £50 a year, and this was agreed to.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND: SOUTH-EASTERN DIVISION.—A successful meeting of the South-Eastern Division of the Medico-Psychological Association was held at Hanwell Asylum on April 26th, and was attended by a large number of the members of the division. After the wards of the historic building had been inspected the members were entertained to luncheon by Dr. Percy J. Baily, the medical superintendent. Subsequently, at the meeting of the division, Dr. Baily read a paper giving an account of the history of the institution, with special reference to the time when Conolly put into practice his humane ideas of non-restraint in the treatment of the insane. Papers were also read by Dr. H. Devine on Kraepelin's clinic and by Dr. Phillips on the treatment of Melancholia by the Lactic Acid Bacillus.

THE Manchester and District Cambridge Graduates' Medical Society was formally constituted on April 27th, at a meeting held at the Queen's Hotel, Manchester. Its object is to forward the interests of the University of Cambridge and to encourage intercourse between Cambridge medical men in the district. After the meeting, at which the scope and rules of the society were considered, a dinner was held at which 27 members, 4 associates (Cambridge medical students who are finishing their course in Manchester), and 8 guests were present. Speeches were made by the Rev. Peter Green, Dr. H. R. Hutton, Dr. G. R. Murray, Mr. E. D. Telford, and the president, Dr. A. Godson. Sir Clifford Allbutt, the Regius professor of physic in the University, was unfortunately unable to be present. Dr. Murray was elected vice-president for the ensuing year. It is hoped that all Cambridge men in the district will be able to join and so strengthen the tie to their old University.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Caxton House, Westminster, on April 26th, with Dr. F. H. Champneys in the chair, at which the Bill to amend the Midwives Act, 1902, was considered. According to the memorandum the Bill is for the most part founded upon the report of the Departmental Committee appointed to consider the working of the Midwives Act, 1902 (1909, Cd. 4822), but departs from the recommendations of that committee in one or two details. The effect of the reconstitution of the Central Midwives Board will be to increase the number of the Board from 9 to 13 members, representation being given to the following bodies, who were previously unrepresented: the Local Government Board, the Association of Municipal Corporations, the Society of Medical Officers of Health, and the British Medical Association. The member appointed by the last-mentioned association must be a medical practitioner. No special qualification is prescribed in the case of the members appointed by the other new bodies. In addition to this increase in numbers, the qualifications of the members appointed by the Incorporated Midwives Institute and the Royal British Nurses Association will be altered. In the future the members appointed by these bodies must be certified midwives. At present the member appointed by the Incorporated Midwives Institute must be a medical practitioner, whilst with respect

to the member appointed by the Royal British Nurses Association no special qualifications are required. The payment of fees of medical practitioners called in on advice of midwives was then considered. Clause 17, under which this subject is regulated, runs as follows :—

(1) Where a duly qualified medical practitioner has been summoned upon the advice of a certified midwife attending a woman in child-birth to render her assistance in a case of emergency in pursuance of any rule framed by the Central Midwives Board, he shall, subject to regulations to be made by the Local Government Board, be entitled to recover from the board of guardians of the Poor-law union in which the woman resided such fee in respect of his attendance as may be fixed by those regulations. (2) The payment of such fees may, if the board of guardians think fit, be treated as relief by way of loan and be recoverable accordingly. (3) Every board of guardians shall in each quarter send to every local supervising authority concerned a list of the cases within the area of the authority in respect of which fees have been paid by the board of guardians under this section.

The clause was approved by the Central Midwives Board.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—A council meeting of this association was held at the Holborn Restaurant on April 28th, and in the unavoidable absence of Dr. F. G. Crookshank Dr. Rashell T. Davison was voted to the chair. The treasurer (Mr. E. G. Gibbs-Smith) reported that many new members had joined the association since the last meeting of the council, and that there was a good balance in hand after all the expenses had been paid. The secretary (Mr. D. A. Belilios) stated that Mr. F. E. Fremantle, county medical officer of health of Hertfordshire, would read a paper in the Public Health Section of the British Medical Association on the Influence of Part-time Medical Officers of Health on Public Health, and the council expressed the hope that the section would be well attended. It was noted that the Rochdale, Richmond, and Salford divisions of the British Medical Association would instruct their delegates to vote for the rescission of Minute 234 at the representatives' meeting, and that the Salford division would move :—

That in every form of public medical service the system of part-time appointments of medical practitioners should be maintained as far as such appointments can be made consistently with the requirements of the services, and that all public medical officers should be protected in carrying out their duties, should be secured from capricious dismissal or reduction of salary, and should be allowed to participate in any superannuation scheme approved by a Local Government Board.

It was decided to recommend those members who belong to both associations to move so that this resolution would be supported by their delegates at the representative meeting of the British Medical Association. Dr. Davison informed the meeting that a paper was to be read at the meeting of the Urban District Councils Association next July on the Advantages of the Present Part-time Public Health Service.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Spring Recess.

PARLIAMENT has adjourned until Thursday, May 26th. No extended holiday was taken by the House of Commons at Easter owing to the financial situation.

Medical Men and the Finance Act.

The Finance Act for 1909-1910 has now become law. It is a complicated measure extending to a hundred pages. In one particular a concession is made to medical men. Whilst the Budget was last year passing through the House of Commons the CHANCELLOR of the EXCHEQUER recognised that, on the grounds of public convenience, it was inadvisable to discourage the use of motor-cars by medical men in their practice. Accordingly he agreed to introduce into the Bill a provision that if a medical man proved that any motor-car kept by him was kept for the purpose of his profession only half the ordinary duty should be paid in respect of it. As the following is the ordinary scale imposed by the Act, the extent of the remission can be seen at a glance :—

	£	s.	d.
Not exceeding 6½ horse power	2	2	0
Exceeding 6½ but not exceeding 12 horse power ...	3	3	0
,, 12 ,, ,, 16 ,, ,, ...	4	4	0
,, 16 ,, ,, 26 ,, ,, ...	6	6	0
,, 26 ,, ,, 33 ,, ,, ...	8	8	0
,, 33 ,, ,, 40 ,, ,, ...	10	10	0
,, 40 ,, ,, 60 ,, ,, ...	21	0	0
Exceeding 60 horse power	42	0	0

In each case the medical man will pay half those rates.

By the Act a duty of threepence per gallon is levied on motor spirit. Under Clause 85 and Part I. of the fifth schedule a rebate of one-half the duty is made on the motor spirit used for the purpose of supplying motive power to "a motor car kept by a duly qualified medical practitioner while it is being used by him for the purposes of his profession."

Vivisection (Abolition) Bill.

Mr. HODGE'S Vivisection (Abolition) Bill has been printed. It lays down that "it shall not be lawful to subject any animal to vivisection—that is to say, to perform on any live animal, with or without the use of anæsthetics, any experiment or demonstration or inoculation of a nature to give pain or suffering either directly or in its after effects for any pathological, surgical, physiological or other scientific purpose, or for the acquirement of manipulative skill."

Education (Physical Training) Bill.

Mr. FREDERICK WHYTE has introduced into the House of Commons a Bill "to provide for physical training in elementary and other schools." It was read a first time. The Bill is backed by Mr. S. BUTCHER, Mr. RODEN BUXTON, Mr. EDMUND HARVEY, Mr. GEORGE ROBERTS, and Mr. WHITEHOUSE.

The Chairs of Clinical Medicine and Clinical Surgery at Glasgow University.

A Bill to confirm a Provisional Order relating to Glasgow University (chair of Clinical Medicine and chair of Clinical Surgery) has been presented in the House of Lords.

Coroners Law and Death Certification Bill.

Sir WILLIAM COLLINS has introduced into the House of Commons a Bill designed to "amend the law relating to Coroners' Law and the Certification and Registration of Deaths and Burials." It was read a first time. The Bill is backed by Colonel LOCKWOOD, Sir PHILIP MAGNUS, Sir LUKE WHITE, Dr. A. P. HILLIER, Dr. W. A. CHAPPLE, and Mr. O'GRADY.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 27TH.

Forcible Feeding.

Mr. HUGH LAW asked the Secretary of State for the Home Department whether he would now favourably consider the holding of an inquiry into the practice of forcible feeding in prisons and asylums.—Mr. CHURCHILL replied: If the honourable Member considers that any improvement can be effected in the methods employed in asylums and prisons for administering food to persons who refuse to take food naturally and gives me his reasons for thinking so I will consider whether further inquiry in the matter is desirable; but at present I do not know to what end such an inquiry should be directed. The methods now employed are, I believe, those recommended by the highest medical authorities, and I know of no reason for modifying them.

Mr. KEIR HARDIE: Is the right honourable gentleman aware that quite recently—in fact, within the last fortnight—a man who had been forcibly fed subsequently died suddenly and the cause of death was held to be largely due to the forcible feeding employed? If so, does the right honourable gentleman not consider the case one for inquiry?

Mr. CHURCHILL: I do not recognise in any of the cases that have come before me one that answers to the description given by the honourable gentleman. If he knows of such a case and will give me the facts I will consider it.

Mr. KEIR HARDIE: I will send the facts to the right honourable gentleman.

Chinese Pork.

Mr. HAMILTON BENN asked the President of the Local Government Board what quantity of Chinese pork was refused admission into ports of the United Kingdom during March, 1910; upon what grounds was this admission refused; and whether he could state what became of these carcasses.—Mr. BURNS replied: So far as my information goes, some 16,800 carcasses which arrived during last month did not comply with the foreign meat regulations and were re-exported. As to the last portion of my question, perhaps I may be allowed to refer the honourable Member to my replies to similar questions on this subject.

Mr. GIBSON BOWLES: What were the grounds on which they were refused?—Mr. BURNS: They were refused, not because they were unsound or unfit for food, but because they did not comply with the foreign meat regulations under the Food Regulations Act, which stipulate that the carcasses should be imported whole. It was because the backbones were taken out and did not comply with that condition that the carcasses were rejected, and for that reason only.

The Departmental Committee on Coroners.

Sir WILLIAM COLLINS asked the Secretary of State for the Home Department whether he proposed to introduce legislation during the present session to give effect to the recommendations of the Departmental Committee appointed to inquire into the law relating to coroners and coroners' inquests, and into the practice of coroners' courts.—Mr. CHURCHILL wrote, in reply: I have now under my consideration two valuable reports made by this committee, but I fear that as matters now stand I cannot give any pledge as to when it will be possible to propose legislation to carry out its recommendations.

The Cowsheds and Dairies Order (Ireland).

Mr. FRANCIS MEEHAN asked the Chief Secretary to the Lord Lieutenant of Ireland whether he would state how many unions in Ireland had adopted the Cowsheds and Dairies Order; and whether the Local Government Board had in any particular instance taken legal proceedings to enforce the same.—Mr. BIRRELL (by written answer) replied: Arrangements for the administration of the Order have been made in 129 rural and 80 urban districts. Legal proceedings to enforce the Order are pending in two instances.

The Medical Officer of Skibbereen Dispensary District.

Mr. GUINEY asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that the Skibbereen, county Cork, Board

of Guardians, on Jan. 19th, 1910, unanimously elected as medical officer of the Skibbereen dispensary district Dr. Michael Burke; whether he was fully qualified for the position; and whether, seeing that the Skibbereen Board of Guardians had twice since the election unanimously requested the Local Government Board for Ireland to sanction the appointment, he would say for what reasons the Local Government Board had refused their sanction.—Mr. BIRRELL wrote in reply: Dr. Burke is at present medical officer of Union Hall dispensary, and has been elected to the vacant medical officership of Skibbereen dispensary. The Board have not sanctioned his transfer, as legal proceedings are being taken with respect to the medical officership of the Skibbereen workhouse, to which Dr. Burke also claims to have been appointed. The Board are awaiting the result of these proceedings, as they do not consider that one medical officer should hold both the dispensary and the workhouse hospitals.

Tuberculous Cows.

Mr. REES asked the Parliamentary Secretary to the Board of Agriculture whether he was aware of the opinion held by rural district councils that provision should be made by law for the payment of reasonable compensation to dairy farmers for loss caused by any proceedings or action of any authority acting under the powers of any Acts of Parliament or Orders made thereunder, relating to milk from cows suffering or suspected to be suffering from tuberculosis, and that the refusal of such compensation, besides being in itself a hardship to dairy farmers, tended to operate against the beneficial working of such Acts and Orders and the prompt detection and eradication of tuberculosis in cattle; and whether the Board of Agriculture proposed that such compensation should be awarded from the Imperial Exchequer, and not from local rates.—Sir EDWARD STRACHEY (in a written answer) replied; Yes; the Board are well aware of the views held by rural district councils on this matter. It would, however, be necessary to introduce legislation to give effect to them, and the Board are not at present in a position to do so, as it would not be practically uncontroversial.

THURSDAY, APRIL 28TH.

The King of the Belgians and Tropical Diseases.

Mr. REES asked the Under Secretary of State for the Colonies whether the Secretary of State had information to the effect that the King of the Belgians had made a large grant of money for the investigation of sleeping sickness and other tropical diseases.—Colonel SEELY replied: I understand that the King of the Belgians has granted 1,000,000 francs for the Service de l'Hygiène in the Congo to be specially devoted to combating sleeping sickness, and 500,000 francs for the construction of native hospitals.

Medical Practitioners and the Midwives Act.

Mr. HENRY WALKER asked the President of the Local Government Board, with reference to the payment of the medical practitioner called in on emergency under the Midwives Act, whether this payment was being made in some places by the local sanitary authority, under Section 133 of the Public Health Act, and in others by the board of guardians, under Section 2 of the Poor-law Amendment Act of 1848; whether any such payment had been disallowed by the district auditor; whether the law officers of the Crown had advised that a board of guardians had any authority, in the absence of an application for parochial relief, to make the payment otherwise than under Section 2 of the above-mentioned Act of 1848; whether, when the payment was made under that section the board of guardians was entitled to recover the amount from the patient or her husband; whether he was aware that some boards of guardians are attempting to recover the amount disbursed under these circumstances to the great hardship of poor persons; and whether he would make publicly known the fact that boards of guardians were not legally entitled to recover such sums.—Mr. BURNS wrote in reply: I understand that in two or three cases payments of the kind referred to have been made by the local sanitary authority under Section 133 of the Public Health Act, 1875, and I believe some boards of guardians have made similar payments under Section 2 of the Poor-law Amendment Act, 1848. I do not find that any such payments have been disallowed by the district auditor. I have not found it necessary to consult the law officers of the Crown on the subject, but I may say that the Board are advised that payments to medical practitioners under Section 2 of the Act of 1848 in such circumstances as are here in question could not be recovered as relief on loan. My attention has only been called to one case of complaint that the guardians were unduly pressing for repayment. The question of my honourable friend and my reply will no doubt give publicity to the matter, and it does not appear to me to be necessary to adopt the course suggested in the last part of the question.

Sir WILLIAM COLLINS asked the right honourable gentleman whether, under the Midwives Act, 1902, or under any rules made thereunder, it was obligatory on a midwife to notify a medical practitioner that his attendance was in certain abnormal cases required; and whether, in the event of payment of such practitioner by the local authority, such payment was deemed to be parochial relief.—Mr. BURNS (by written answer) replied: Under Rule 18 of the rules framed by the Central Midwives Board, and approved by Order of Council of April 24th, 1907, it is the duty of the midwife, in certain specified circumstances of danger, to represent to the husband or the nearest relative or friend of the patient that a medical practitioner should be summoned, and to fill in the requisite form to that effect. The question whether payments made by a local authority would be parochial relief will depend largely on the circumstances of the case.

BOOKS, ETC., RECEIVED.

APPLETON, D., AND CO., New York and London.

Surgical Diagnosis By Alexander Bryan Johnson, Ph.B., M.D. Three volumes. Price, cloth, £3 15*s.* net.

Preparatory and After Treatment in Operative Cases. By Herman A. Haubold, M.D. Price, cloth, 25*s.* net.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—Surgeon.

SALISBURY, FISHERTON HOUSE ASYLUM.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and attendance.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.

SHEFFIELD, WEST RIDING ASYLUM, Wadsley.—Fifth Assistant Medical Officer. Salary £140 per annum, with board, &c.

SOUTHPORT INFIRMARY.—Junior House and Visiting Surgeon, unmarried, for six months. Salary at rate of £70 per annum, with residence, board, and washing.

SOUTH SHIELDS, INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Senior House Surgeon. Salary £100 per annum, with residence, board, and washing.

SOUTHWARK UNION INFIRMARY, East Dulwich-grove, S.E.—Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing.

STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry.

STAMFORD, RUTLAND, AND GENERAL INFIRMARY AND FEVER HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

SWANSEA GENERAL AND EYE HOSPITAL.—House Physician. Salary £75 per annum, with board, washing, and attendance.

TAUNTON, TAUNTON AND SOMERSET HOSPITAL.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

TOWER HAMLETS DISPENSARY, Whitehorse-street, Stepney, E.—Resident Medical Officer. Salary £100 per annum, with apartments, &c.

TYNEMOUTH, VICTORIA JUBILEE INFIRMARY, Spring Gardens, North Shields.—House Surgeon. Salary £100 per annum, with rooms, board, &c.

WEST LONDON HOSPITAL, Hammersmith-road, W.—House Physician for six months. Board, lodging, and laundry allowance provided.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon. Salary £80 per annum, with board, rooms, and laundry

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Elstree, in the county of Hertford; and at West Huddersfield, in the county of York.

Births, Marriages, and Deaths.

BIRTHS.

DUNNETT.—On April 30th, 1910, at 7, Ascott-avenue, Ealing, Agnes Dunnett, M.B. Lond., wife of Lionel Francis Dunnett, of a son.

LOCKYER.—On May 1st, at Harley-street, W., the wife of Cuthbert Lockyer, M.D., F.R.C.S., of a son.

MORISON.—At 1, Claremont-place, Newcastle-upon-Tyne, on April 27th, the wife of Professor Rutherford Morison, of a son.

SPENCER.—On April 29th, at Arrow-road, Alcester, Warwickshire, to Dr. and Mrs. R. H. Spencer, a son.

MARRIAGES.

FORBES—HALL.—On April 30th, at St. Nicholas' Church, Brighton, Dr. Duncan Forbes, Medical Officer of Health, Brighton, to Kathleen Penfold, youngest daughter of Edwin Penfold Hall, Brighton.

DEATHS.

BURY.—On April 23rd, at Wisbech, Edward Charles Bury, M.D.

MORISON.—At 1, Claremont-place, Newcastle-upon-Tyne, on May 2nd, Lull, wife of Rutherford Morison.

WETHERED.—On April 25th, at Kingswood, Surrey, Ernest Wethered, M.D., aged 34 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

PUBLIC HEALTH IN EGYPT.

REPORTS by His Majesty's Agent and Consul-General (Sir Eldon Gorst, K.C.B.) on the condition of Egypt and the Soudan in 1909 were issued as a Parliamentary paper on April 28th. In Egypt the work of the Government hospitals and dispensaries continues to show satisfactory progress. The in-patients treated during the year numbered 37,000, while in the out-patient department a total attendance of over 350,000, including 144,500 new patients, is recorded. Some 33,000 persons have been attended by the district medical officers. The improvement observable during recent years in the quality of the work done is largely to be attributed (the report declares) to the excellence of the course of education at the School of Medicine. The two travelling ophthalmic hospitals (an account of which was given in THE LANCET of April 9th, p. 1013) visited Mansourah, Ghizeh, Beni-Souef, and Luxor during the year, working between them on 442 days. Over 7000 new patients were treated, and the total number of attendances was 100,000, giving an average of 221 per working day in each hospital. More than one-third of those attending for treatment were under 15 years of age. The popularity of the service amongst the fellaheen is of good augury for the future, and it may be hoped that in time some appreciable effect will be produced on the mass of ophthalmia prevalent in the country. At Tantah 5000 new cases were dealt with in the permanent ophthalmic hospital, and there were 77,000 visits by patients under treatment. 1763 major and 2418 minor operations were performed. The ophthalmic hospital at Assiout is nearly finished. The construction of the Mansourah hospital will, it is hoped, be begun this year. Efforts are being made to deal with ophthalmic cases in the Government schools by instructing the teachers, and through them the students, in some of the simple rules of hygiene. The staff of this department is to be reinforced by an English inspector in view of the great increase of work.

The accommodation at the Abbassieh Lunatic Asylum has been raised from 877 beds to 947, and the total will soon be increased to 1007. Good progress has been made with the construction of the new asylum at Khanka. During 1909 546 patients were admitted to the Abbassieh Asylum, 101 cases being due to pellagra and 43 to hashish. An investigation has been instituted into the causes of the former obscure disease, and the work is proceeding on much the same lines as have been proposed in the case of the committee recently formed in London to study the subject.

There was a marked diminution in plague during 1909, especially in the more dangerous pneumonic form. The total number of cases was 513, as compared with 1511 in 1908, while the number of deaths fell from 780 to 207. The special organisation established two years ago in the southern provinces for dealing with the disease has largely contributed towards this satisfactory result. Disinfecting stations with the necessary appurtenances and a competent staff have now been supplied to each Mondirieh. A supernumerary staff of trained disinfectors is kept in readiness at headquarters, and a plague medical staff has been organised ready to proceed at short notice to an infected locality. The campaign waged against plague for the last 10 years has been productive of many indirect advantages in addition to its direct effect in preventing the spread of this terrible scourge.

Last year the death-rate of children under one year assumed unusual proportions in Cairo. The weekly rate, which is about 136 on the average, rose to 130 in the latter part of March, 188 towards the end of April, and 664 in the middle of May. The figures for the next four weeks average 573, the maximum reached being 700. Then came a sudden drop to 248 in July, followed by a further gradual decline till in December the mean of the previous winter was reached. High infant mortality may be observed during the summer in all hot countries, being generally due to digestive troubles, but the immediate cause of the unusually serious outbreak in Cairo last year has not so far been discovered. Careful and thorough investigation is necessary before any definite conclusion can be arrived at. The Lady Cromer dispensaries are endeavouring to instil elementary ideas on the subject of cleanliness and the rational bringing up of children among the poorer classes. It is understood that the Princesses of the Khedivial family have recently decided to establish a society for the protection of infant life.

The anti-mosquito movement in Cairo was first started in 1902, the measures adopted consisting in oiling cesspools, wiring ventilators, putting fish into ornamental waters, and removing stagnant water. These measures have met with a certain amount of success, though not sufficient to permit the disuse of mosquito curtains; in fact, so long as excavations and low-lying spots exist which contain infiltration water during high Nile, mosquitoes will continue to breed in Cairo. No doubt the steps now taken are efficacious within certain limited areas, but a much more effective cure will be the completion of the drainage scheme. In Port Said the anti-mosquito campaign has been carried on in more favourable circumcumstances, and has, owing to the compact area of the town and the absence of infiltration, resulted in a distinct improvement in the conditions of life. The anopheles mosquito is but rarely found in Cairo and Port Said. In Suez and Ismailieh the measures taken to stamp out the anopheles mosquito have, as is well known, produced great improvement in the public health.

During the year 16 students in the School of Medicine obtained their diplomas, one student died, and 17 left; in October 50 new students joined. There are at present 206 students in the School of Medicine and one in the School of Pharmacy. The anatomical department sustained a great loss during the year through the resignation of Professor G. Elliot Smith on his appointment to the chair of anatomy at the University of Manchester. Dr. Bahgat Wahby, an Egyptian, was appointed in his place, and three demonstrators have been added to the staff.

In the Soudan three new hospitals were opened during the year—at Khartoum, Atbara, and Port Soudan. The buildings are satisfactory, but various accessory constructions are still required in the two former. The Soudan medical department has been placed under the direction of Colonel H. B. Mathias, principal medical officer of the Egyptian army. Dr. J. B. Christopherson has been appointed director of the Khartoum and Omdurman civil hospital. The number of out-patients treated increases steadily, and about 140,000 were treated in 1909, as compared with 121,000 in the preceding year. The number of in-patients remains at about 7,000. 41,000 vaccinations were performed during 1909, as against 19,000 in 1908. There was little small-pox in the country, nor has there been any serious epidemic of infectious disease during the year. A report on the subject of sleeping sickness has been furnished by Captain R. G. Anderson, who has been conducting investigations on the boundary of the Bahr-el-Ghazal and the Lado Enclave, and valuable suggestions are made regarding measures of precaution against the introduction of the disease into the Soudan from that quarter. An inquiry has also been instituted into the causes of the obscure and fatal disease known as kala-azar which has in recent years appeared in the Kassala province and on the Blue Nile.

AN OBSTINATE CASE OF NOCTURNAL ENURESIS.

To the Editor of THE LANCET.

SIR,—In reply to your correspondent who asked in your issue of April 23rd for suggestions in the treatment of an obstinate case of nocturnal enuresis of 18 months' duration, the patient being a girl of 18 years of age suffering also from Graves's disease, all the usual remedies having been tried without any permanent success, I feel it would more than likely contribute to the patient's interests and those of her medical attendants were the latter to give an opportunity to hypnotic suggestion. I recommend hypnotic advisedly, for simple suggestion—now so popular an idea possibly because hypnotism is so little understood—would be found to have but transient and insignificant power in such a case. I have observed an instance of Graves's disease appearing to improve under simple suggestion when symptoms and general condition have been treated medicinally and hygienically meanwhile; but I am of opinion that hypnotic suggestion, if properly applied, would effect rapid improvement in your correspondent's case, both as respects the particular disease and the intercurrent urinary disorder. The fact that she sleeps heavily and is awakened with difficulty is interesting and suggests a toxæmia serving to "fill up the cup" of complication and difficulty; but, to my mind, making the probability all the greater that a course of hypnotic treatment would effect a cure all round.

I am, Sir, yours faithfully,

Caterham, April 24th, 1910. HAYDN BROWN.

To the Editor of THE LANCET.

SIR,—In answer to "Wanted Suggestions for Treatment" I have treated a fair number of cases of enuresis by hypnotic suggestion most successfully after other means have failed. I should be very glad to hear from your correspondent on the subject.

I am, Sir, yours faithfully,

75, Warwick-square, S.W., April 27th, 1910. A. G. BUCHANAN.

THE ABUSE OF FIRST AID.

UNDER the title of "The Most Curious Hospital in London Town" the *Graphic* has recently printed a picture of an ambulance station under the steps of St. Paul's Cathedral, in which an officer of the St. John Ambulance Association is surgically treating a man whose dress would suggest that he does not belong to the poorer classes of the community. The letterpress states that the ambulance station was opened in 1890, is open daily, including Sunday, that on all occasions of special services in the Cathedral the permanent attendant is assisted by volunteers of both sexes, and that the total number of cases treated up to date is 8067. The St. John Ambulance Association undoubtedly serves a very important purpose in our crowded metropolis, where accidents must almost inevitably be of daily occurrence, but it is not for the benefit of the public that the work of its officers should extend beyond that of rendering first aid and of promptly removing a patient to a hospital or the house of a medical man. A correspondent informs us, however, that at the station under the Cathedral anyone who chooses to go to th attendant in charge can receive treatment. We are also informed that the attendant when called upon visits any

of the neighbouring buildings. This is certainly going beyond the legitimate scope of the Association, and those responsible for the management of the station in question must see on reflection that with the best of intentions they are doing work which can only be properly done by a medical man.

FROM THE OUT-PATIENT ROOM.

To the Editor of THE LANCET.

SIR,—Perhaps you may find space in your columns for the following—a jewel dropped in the out-patient room at a certain hospital. It seems worthy of preservation. Physician asks the patient, a youth, whether there is anything in his family history worthy of note and receives this remarkable reply: "Please, sir, I've got piles on my mother's side."

We are familiar with the fact that when the fathers have eaten sour grapes the children's teeth are set on edge (presumably Hutchinson's peg-top teeth), but this seems to add new and terrible sequelæ to the constipation of the mothers. I am, Sir, yours faithfully,

C.

WESTON AND HIS WALKS.

IN THE LANCET of April 16th (p. 1112) last we announced the transcontinental walk of Mr. E. P. Weston, a septuagenarian pedestrian, from Los Angeles, California, to New York. He left Los Angeles on Feb. 1st and was due to arrive at the City Hall, New York, on May 17th, the scheduled time to be occupied being 90 days, not including Sundays, when he rests. We now learn that Mr. Weston reached New York on May 2nd, so that he has completed the walk in 77 days, or with 13 week-days to the good.

A CURE FOR BLOOD POISONING.

Kans City, Mo., Mar. 28, 1910.

To the London LANCET, *London, England.*

GENTS,—Pardon me for taking the liberty of addresing you. I am now past eighty-four years old and I am the original discover of a posative cure for blood poison and lock jaw, it has not failed in five cases, four of lock jaw and one of blood poison, three of them the doctors had gave up to dye. I can cure a case incide of thirty minits, it is veary simple and easy to hanble, I do not want it to dy with me, as it is worth thousands of dollars to suffering humanity. I have this month March sent it to the Medical Faculty of New York City, and will send it to Chicago, Ills., also. Now gentleman, I am No doctor and only an old mechanic and veary needy in my old age, most eighty-five years old and nearly blind also. After you make a fare test of my formaly and find that it will do what I say it will cure lock jaw and blood poison in thirty minits time, then if you can then feel like asisting me, make your own price according to your generosity and I will be satisfied. Direct to ——, 333, North Londale, Kansas City, U.S.A. A formuly to cure lock jaw. Get three or four oz. of good smokeing tobacco, brake it upon a paper, then get an iron bucket or stone pot, put into it two or three shovels of live coals of fire, hold the wounded hand or foot two feet above the pot, drop the tobacco on the fire, cover all with a quilt and smoke for thirty minits, and there you are. I am, yours truly,

333, North Londale, Kansas City, Mo., U.S.A. ——.

PHARMACOLOGICAL EXHIBIT AT THE BRUSSELS EXHIBITION.

ONE of the features of the Brussels Exhibition is the imposing exhibition of Messrs. Burroughs, Wellcome, and Co., near the entrance to the Galerie de l'Industrie Britannique. Here are shown the firm's well-known tabloid products, animal substances, and the organic arsenic compounds; and as an instance of the pitch to which the preparation of pharmacological products has attained the fact may be mentioned that this firm when unable to obtain medicinal herbs conforming to a high standard of efficiency grow their own on a large scale.

Doubtful.—We do not think that there is any objection to the course suggested by our corespondent, provided that none but patients on the books are communicated with.

Canvassed has not inclosed his name and address.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—Walter G. Spencer, Jonathan Hutchinson) at the Botanical Theatre, University College, W.C.: at 5.30 P.M.

Discussion:

On the Present Position of the Treatment of Syphilis. (To be continued at the next meeting on June 14th.) Mr. Ernest Lane will open the Discussion, and Sir Jonathan Hutchinson, Dr. Alexander Fleming, Mr. Arthur Shillitoe, Mr. H. W. Bayly, Mr. J. E. R. McDonagh, Dr. F. J. Smith, Mr. C. F. Marshall, Dr. G. Pernet, Mr. Charles Gibbs, and Captain Rennie will take part.

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—W. J. Gow, G. F. Blacker) at 15, Cavendish-square, W.: at 7.45 P.M.

Papers:

Dr. F. J. McCann: Cæsarean Section in the Treatment of Eclampsia Gravidarum.

Dr. A. J. Wallace; Contribution to the Life History of Fibromyomata of the Uterus.

FRIDAY.

CLINICAL SECTION (Hon. Secretaries: H. D. Rolleston, Albert Carless) at 15, Cavendish-square, W.: at 8.30 P.M.

Dr. Henry Head will give a Demonstration on Clinical Methods for Testing Sensations (illustrated by cases).

Dr. R. G. Hebb: Lympadenoma with Pruritus and Cutaneous Tumours.

Dr. A. C. Firth: A Case of Pink Urine caused by Eating Highly-coloured Sweets.

Dr. R. C. Elmslie: (1) Three Cases of Enlargement of the Tubercle of the Tibia (Schlatter's Disease); (2) A Case of Fracture of the Humerus at the Site of an Innocent Cyst. And other Cases.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8 P.M., Annual Meeting; Election of Officers, &c., for 1910–11 Session. 8.30 P.M., Tropical Diseases to be Demonstrated by the Epidiascope:—(1) Sir Patrick Manson: Malaria; (2) Dr. F. M. Sandwith: Ankylostomum Duodenale and the Entrance of its Larvæ through the Skin into the Human Body; (3) Dr. C. Brown: Tropical Dysentery; (4) Dr. A. W. G. Bagshawe: Sleeping-Sickness.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, S.W.

WEDNESDAY.—4.30 P.M., Clinical Demonstrations.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. G. Pernet: Clinique (Skin). 5.15 P.M., Lecture—Dr. T. Eden: Some Common Difficulties in Forceps Delivery.

TUESDAY.—4 P.M., Dr. P. Stewart: Clinique (Medical). 5.15 P.M., Lecture:—Dr. T. C. Shaw: Suggestion, Hypnotism, and Telepathy.

WEDNESDAY.—4 P.M., Mr. J. Cantlie: Clinique (Surgical). 5.15 P.M., Lecture:—Mr. J. Bland-Sutton: Injuries of the Heart.

THURSDAY.—4 P.M., Dr. J. Mackenzie: Clinique (Medical). 5.15 P.M., Lecture:—Mr. J. Clarke: Internal Derangements of the Knee joint.

FRIDAY.—4 P.M., Dr. W. Hill: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith road, W.

MONDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Davis: Diseases of the Throat, Nose, and Ear.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 10.30 A.M., Demonstrations in Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Operations of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. S. Taylor: Acute Rheumatism.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine.

THURSDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture: Dr. Davis: Diseases of the Throat, Nose, and Ear.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. Medical Registrar: Demonstration of Cases. 2 P.M., Dr. Davis: Diseases of the Throat, Nose, and Ear. X Rays. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Abraham: Cases Skin Disease.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Diseases of the Throat, Nose, and Ear. Mr. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4 P.M., Special Lecture:—Dr. R. Lake: Nasal Obstruction.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 2.15 P.M., Special Lecture:—Dr. F. Taylor: Empyema.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4 P.M., Special Lecture:—Dr. C. Hawthorne: Some Aspects of Rheumatism in Early Life.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. P. Kidd: Bronchiectasis.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Mr. J. G. French: Tracheoscopy, &c.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. G. Holmes: Functional Localisation in the Brain.

FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. Ormerod: Tabes Dorsalis.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

TUESDAY.—3 P.M., Prof. F. W. Mott: The Mechanism of the Human Voice. (Lecture III.)

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (9th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (14th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Mr. J. Arblaster, Birmingham; Ashton-under-Lyne Union, Clerk to the; Messrs. C. Ash, Sons, and Co., Lond.; Anglo-American Pharmaceutical Co., Croydon; Dr. E. Ash, Lond.; Dr. B. Anningson, Cambridge.

B.—Messrs. Blundell and Rigby, Lond.; Mr. A. Burrows, Lond.; British Diamalt Co., Lond.; Mr. J. Bolingbroke, Stockport; Messrs. J. Baker and Son, Bristol; Bury Infirmary, Secretary of; Mr. F. A. Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

The Arris and Gale Lectures

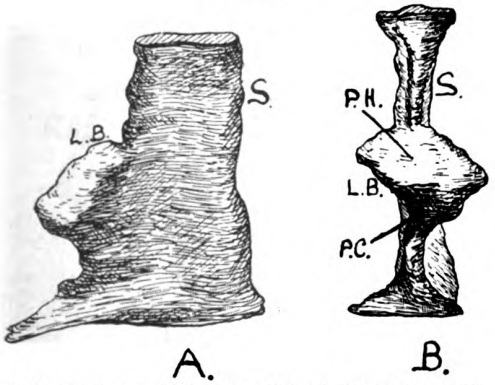
ON

SOME EMBRYOLOGICAL PROBLEMS IN RELATION TO MEDICINE.

Delivered before the Royal College of Surgeons of England on Feb. 28th and March 2nd, 1910,

BY PETER THOMPSON, M.D. VICT.,
PROFESSOR OF ANATOMY IN THE UNIVERSITY OF BIRMINGHAM.

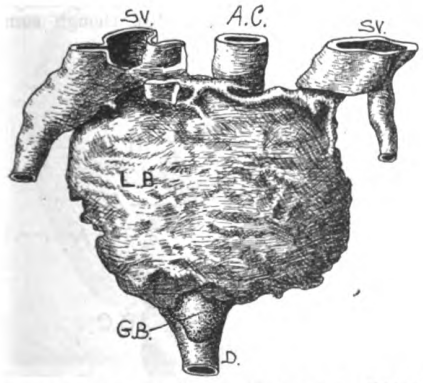
LECTURE II.[1]



Delivered on March 2nd.

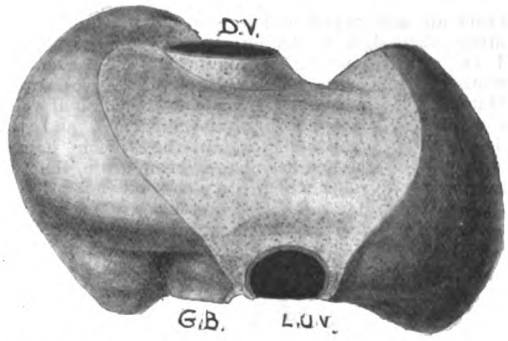
THE LIVER.

MR. PRESIDENT AND GENTLEMEN,—In its first appearance the liver is very early, forming as an outgrowth from the alimentary canal in embryos of 13–14 paired somites. In a 2·5 mm. human embryo, which shows 23 paired somites, the liver bud exhibits an interesting stage which forms a good starting point to study its development. The bud grows out from the alimentary tube opposite the third and fourth cervical somites as a median structure with relatively thick walls inclosing a cavity in communication with the alimentary canal (Fig. 10). In sagittal section it is seen growing into the septum transversum. When viewed from the front the greater part of the outgrowth is on the left of the middle line, and as yet there is no outward indication of the gall-bladder. If, however, the sections themselves are carefully examined under the microscope, liver trabeculæ are found at the cephalic end of the outgrowth, and thus a differentiation into two parts, cephalic and caudal, becomes manifest. These two parts have been designated by Maurer the "pars hepatica" and the "pars cystica," since from the former the liver is mainly derived and from the latter the gall-bladder. This is clearly seen in Ingalls' embryo (4·9 mm. long) at the early part of the fourth week (Fig. 11). The liver has assumed a crescentic form, and when looked at from the front one recognises the gall-bladder distinct from the liver and occupying a position immediately caudal to the point of junction of the duct of the liver bud with the fore-gut. The liver outgrowth is now placed opposite the sixth and seventh cervical somites. Towards the end of the first month the liver has the form seen in Figs. 12 and 13. It is still somewhat crescentic in outline, but the right lobe is larger than the left. Ventrally is seen an extensive area corresponding to the interval between the two layers of the falciform ligament, at the lower part of which enters the left umbilical vein (Fig. 12). To the right of the vein is the mass of mesoderm containing the gall-bladder, the quadrate lobe being still undeveloped. From the upper border of the model a large vein emerges, the ductus venosus Arantii.



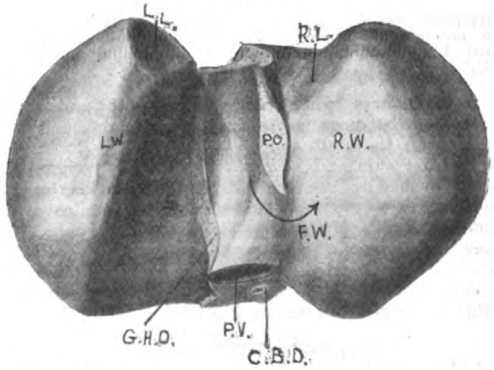
Posteriorly is the attachment of the gastro-hepatic omentum, the plica venæ cavæ occupying the place where the inferior vena cava will subsequently form, the foramen of Winslow indicated by the arrow, the portal vein, and the commencement of the lobus Spigelii. (Fig. 13.) The various areas of contact with neighbouring organs are indicated in

FIG. 10.



Model of entodermal tube showing the hepatic bud. × 70. A, seen from the left side; B, from the front. Human embryo, 2·5 mm. in length. L.B., liver bud; S., stomach; P.H., pars hepatica; P.C., pars cystica.

FIG. 11.



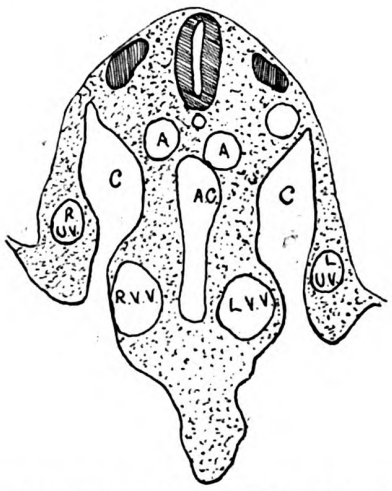
Entodermal tube showing the hepatic bud and gall-bladder. Human embryo, 4·9 mm., modelled by Ingalls. A.C., alimentary canal; D., duodenum; L.B., liver; G.B., gall-bladder; S.V., two parts of sinus venosus receiving veins.

FIG. 12.

Model of liver from a human embryo, 7 mm. in length. × 37½. Seen from the front. G.B., gall-bladder; L.U.V., left umbilical vein; D.V., ductus venosus. The stippled area indicates the interval between the two layers of the falciform ligament.

FIG. 13.

The same as Fig. 12, seen from behind. L.L., impression for left lung; R.L., impression for right lung; L.W., impression of left Wolffian body; R.W., same for right Wolffian body; S., area of stomach contact; G.H.O., gastro-hepatic omentum; P.C., plica venæ cavæ; F.W., foramen of Winslow; P.V., portal vein; C.B.D., common bile-duct.



[1] Lecture I. was published in THE LANCET of May 7th, 1910, p. 1247.

Fig. 13. The liver is now placed opposite the upper thoracic somites.

The foramen of Winslow lies caudal to the vena caval mesentery. Where the latter ends the great sac of the peritoneum comes into communication with the lesser sac by a long narrow passage extending across the back of the liver. The lesser sac, or bursa omentalis, is placed between the gastro-hepatic omentum on the left and the plica venæ cavæ on the right. Cranialwards it is prolonged beyond the upper limit of the liver and comes into relationship with the right side of the œsophagus, where it is known as the peri-œsophageal cœlom. This is limited cranially by the septum transversum, and as the dorsal border of the latter descends in relation to the posterior body wall, the peri-œsophageal cœlom becomes progressively diminished in height and finally disappears. It is seen in human embryos from 7 mm. up to 18 or 20 mm.

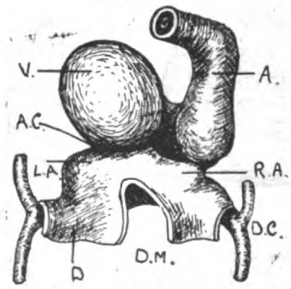
The fact that the right lobe of the liver is larger than the left at such an early stage is both interesting and significant—interesting, that such a characteristic of the adult organ should be manifest so early; significant, on account of certain other factors with which this feature is associated. In rabbit embryos of about ten days the abdominal veins according to Lewis are absolutely symmetrical, and the same is true for human embryos. In the 2·5 mm. human embryo, to which reference has already been made, the two omphalo-mesenteric veins which are placed on either side of the intestinal canal and the two umbilical veins lying in the somatopleure are practically symmetrical (Fig. 14).

FIG. 14.

Transverse section of human embryo, 2·5 mm., at the level of the umbilicus. A., aorta; C., cœlom; A.C., alimentary canal; L.V.V. and R.V.V. left and right vitelline veins; L.U.V. and R.U.V., left and right umbilical veins.

Owing to influences which are not as yet understood "this system becomes asymmetrical and normally is predominant on the right side." The liver develops more rapidly on that side and becomes a right-sided organ, the stomach is pushed to the left side (see Fig. 8, Lecture I.), and the plica venæ cavæ in which the inferior vena cava will subsequently form persists on the right side only. As F. T. Lewis observes: "It may confidently be assumed that had the original symmetrical veins become predominant on the left side, stomach, liver, and later the inferior vena cava would shift their position resulting in situs inversus."

THE HEART.



Descriptive accounts of the early stages of development of the heart in the human embryo—i.e., during the first month—are not yet sufficiently numerous to enable us to obtain a satisfactory conception of what takes place. Apart from the difficulties of obtaining material the interpretation and labelling of the various parts of the heart tube are by no means easy, and sometimes give rise to considerable perplexity and doubt. In this connexion the study of abnormal hearts, combined with the wax reconstruction of the cardiac tube in young embryos, has greatly extended our knowledge, and has shown the supreme importance of studying conditions which, though transitory in normal development, may under adverse circumstances become permanent.

The series of changes, both in form and arrangement, which the heart undergoes during the third and fourth weeks are complicated. Physical influences apparently play an important part. As the heart tube is fixed at its two ends, venous and arterial, increase in length of the intermediate moveable part leads to the formation of a loop—the ventricular loop—and the "packing" of the loop into that part of the pericardium best suited for its reception at the time gives rise to an interesting condition, in which the apex of the loop, instead of being in contact with the septum transversum (central part of future diaphragm), as one might expect, is placed far over on the right side (see Figs. 18 and 19).

I now wish to describe, as far as I can from the material at my disposal, what I conceive to be the ontogenetic development of the human heart in the third and fourth weeks, considering only changes in form and arrangement of the ventricular loop. The material includes seven specimens, three of my own and four described by other workers, and all but one have been reconstructed in wax. We are thus able to read the series of events fairly successfully, though there are still one or two gaps to fill in before the picture may be regarded as complete. The seven specimens are as follows:—

1.	Embryo	2·15 mm.	(His)
2.	,,	3·0 ,,	(Own specimen)
3.	,,	13-14 somites	(Low)
4.	,,	2·5 mm.	(Own specimen)
5.	,,	4·9 ,,	(Ingalls)
6.	,,	6·8 ,,	(Piper)
7.	,,	7·0 ,,	(Own specimen)

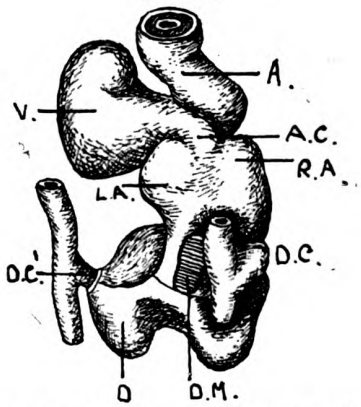


FIG. 15.

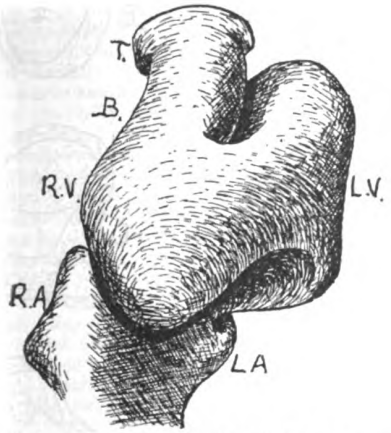
Heart of the His embryo, 2·15 mm., seen from behind. L.A. and R.A., left and right auricles; A.C., auricular canal; V., commencement of ventricular loop; A., aortic end of same; D., diaphragm (septum transversum); D.M., dorsal mesocardium; D.C., duct of Cuvier formed by cardinal veins.

The heart in the His embryo (Fig. 15) is perhaps the best known of the series; for many years it has found a place in all our standard text-books, and yet the difficulty of reading the specimen, on account of the uncertainty regarding the position of the auricular canal, has been felt by many. The heart of the 3 mm. embryo (Fig. 16), though somewhat

FIG. 16.



Heart of 3 mm. human embryo seen from behind. L.A. and R.A., left and right auricles; A.C., auricular canal; V. and A., beginning and end of the ventricular loop; D.C. and D.C.1, right and left ducts of Cuvier; D.M., dorsal mesocardium; D, septum transversum

older, is of interest in this connexion, since it appears to confirm completely the interpretation which His originally placed upon his specimen. By comparing Figs. 15 and 16 it will be noticed that although there are obvious differences in arrangements of the parts, the parts themselves closely agree. The auricles are in Fig. 16 more expanded, but the auricular canal retains the same relative position in both.

It will further be noticed that in the two specimens under consideration the increase in length of the heart tube is most marked at the arterial end where the ventricle is developing, and here a definite bend is formed, the ventricular loop. The shape of the loop is not unlike that of the stomach, the cardiac and pyloric ends, as well as the lesser and greater curvatures being recognisable (Fig. 17). Whilst the auricles continue to enlarge and

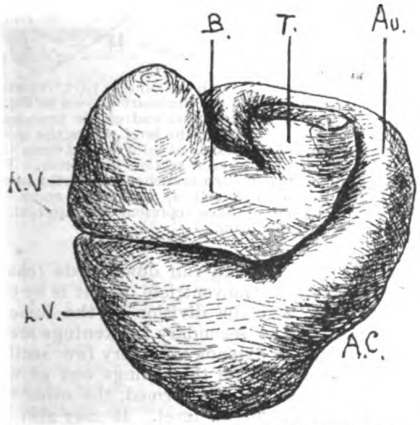


FIG. 17.

Ventricular loop of same heart as shown in Fig. 16, seen from the front, × 100. L.V., left ventricle; R.V., right ventricle; B., bulbus; T., truncus; L.A. and R.A., left and right auricles.

extend upwards so as to embrace the aortic end of the tube, the ventricular loop goes through a remarkable series of changes in position, the result apparently of the disproportion between its length and the pericardial cavity which encloses it, and also of the packing away of the loop in the most convenient place. These changes can be followed in Figs. 18 and 19. When the loop first forms it is placed

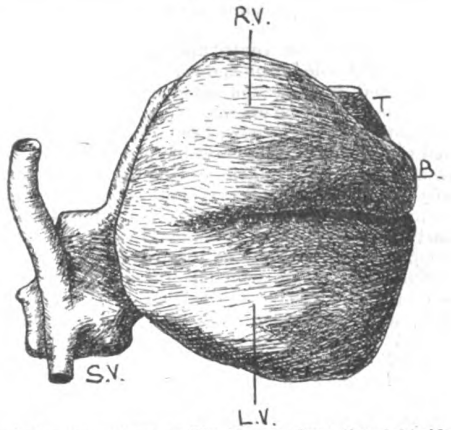

FIG. 18.

Heart of 2·5 mm. embryo, seen from the front, × 75. AU., auricular part of heart, embracing T., the truncus; B., bulbus; R.V., right ventricle; L.V., left ventricle; A.C., level of auricular canal.

ventrally and directed towards the right. Then it rotates round a cranio-caudal axis and comes to lie almost entirely on the right side of the body. The future apex is at the extreme right and the ventricles are placed one above and one below the horizontally disposed cleft related to the lesser curvature. The heart in the embryo of 13–14 somites illustrates this movement at a little earlier stage.

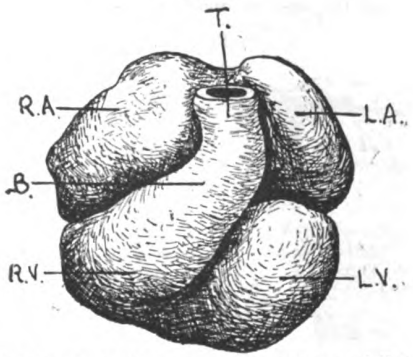

FIG. 19.

Heart of same embryo as Fig. 18, seen from the right side, × 75. B., bulbus; T., truncus; R.V., right ventricle; L.V., left ventricle; S.V., sinus venosus, receiving right duct of Cuvier.

The apex of the loop next moves through about a quarter of a circle, descending from the right downwards towards the middle line (Fig. 20), the lesser curvature cleft becoming

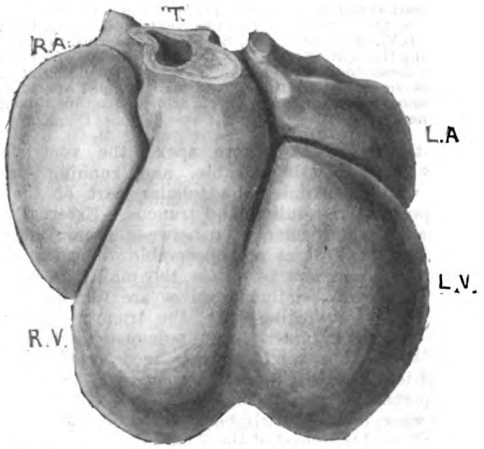

FIG. 20.

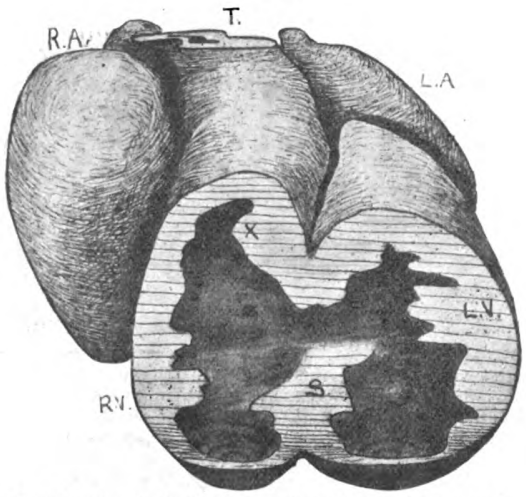
Heart of human embryo 4·9 mm. in length, modelled by Ingalls, × 30. R.A. and L.A., two auricles; R.V. and L.V., two ventricles; B., bulbus; T., truncus.

almost vertical. At the conclusion of the movement the apex is bifid, showing that the two ventricles are beginning to expand caudalwards, and the true apex of the heart—i.e., the extremity of the left ventricle—is now apparent (Fig. 21)

FIG. 21.

Heart of human embryo 7 mm. in length, seen from the front, × 33½. R.A. and L.A., right and left auricles; R.V. and L.V., right and left ventricles; T., truncus, just at the point where it is leaving the pericardial cavity.



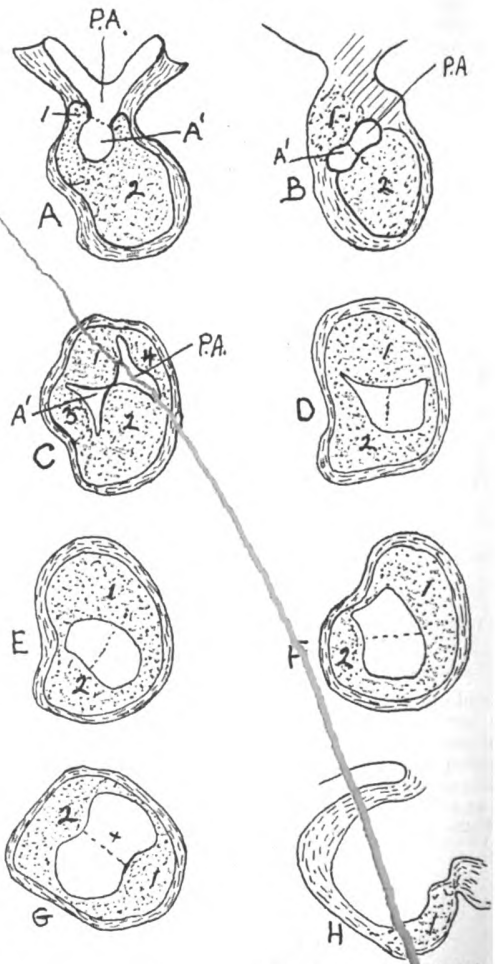
The heart in Ingalls' embryo shows the half-way stage in this descent, and the completion is seen in both the 6·8 mm. and the 7 mm. specimens.

The reason why the ventricular part of the heart passes over to the right side is not known. Various influences have been suggested, such as the asymmetry of the vessels, the pressure of neighbouring organs, &c. A left-sided ventricular loop has not, as far as I know, been observed, but it may be assumed to occur in certain cases of situs inversus.

Turning now to the aortic end of the ventricular loop, a specially interesting feature is noticeable in most of the illustrations of the heart tube—viz., the bulbus cordis. It is that part of the tube lying between the end of the ventricular loop and the aortic stem or truncus. It represents a subdivision of the heart which is present in a marked form in lower vertebrates, such as the shark. It is not necessary for me to give any special account of this chamber, since Professor A. Keith has given in his Hunterian lectures for 1909[2] a full description of its fate and the various abnormalities which may be traced to the arrest of the process which ends in the incorporation of the bulbus in the right ventricle. What I particularly wish to do is to show from the series of specimens with which we are dealing that the bulbus is a well-marked division of the heart in the third and beginning of the fourth weeks, and that towards the end of the fourth week there is no distinct demarcation externally between it and the right ventricle on the one hand, and the truncus on the other. In certain cases, however, where there has been defective development, it may remain distinct.

In Fig. 21 the apex of the heart is bifid—that is to say,

FIG. 22.



Same heart as in Fig. 21, with a piece of the model removed to show the interior of the two ventricles. R.A., L.A., R.V., L.V., same as before; S., septum inferius, partially dividing the ventricles. The X is placed over the lower end of the dorsal endocardial thickening which, beginning at T, is now ventral in position. The small rounded apertures represent the mitral and tricuspid orifices, magnified about 33 times.

each ventricle has a definite apex; the ventricles are externally easily distinguishable, and running upwards from the right ventricle is a tubular part of the heart which represents the bulbus and truncus. Externally there is no clear line of demarcation between them; internally, however, certain features are observable which enable us to say definitely where the two meet, the main one being the level at which the semilunar valves are forming. Above that level we are dealing with the truncus which later becomes divided into aorta and pulmonary artery, whilst below is the bulbus which becomes incorporated with the right ventricle. As this region of the heart tube is of such great importance from the embryological and pathological points of view, it will clearly be advantageous to study it in some detail, and the heart of the 7 mm. embryo is an excellent specimen for the purpose.

[2] THE LANCET, March 13th (p. 745), 20th (p. 825), and 27th (p. 895), 1909.

The series of drawings in Fig. 23 are sections of the tube beginning at the upper (cephalic) end and concluding with one at the level of the communication of the bulbus with the right ventricle. They show that internally are certain thickenings of endocardium, which may be divided into two groups—primary and secondary. The primary thickenings

FIG. 23.

Eight transverse sections through the tubular part, representing the truncus and bulbus of the heart shown in Fig. 22. Section A is from near the upper end of the truncus, T. Section H is taken from about the level where the cross is placed, and the others are taken at intervals between these two. The anterior edge of each section is inferior. P.A., pulmonary lumen and its two branches; A, aortic lumen; 1 and 2, primary, and 3 and 4, secondary endothelial thickenings. The dotted lines represent the approximate position of the future septum.

beginning at the cephalic end run downwards (caudally) in a spiral manner as far as the ventricle, and it is by the fusion of these thickenings that the division of the lumen is subsequently effected. The secondary thickenings are confined to a definite level which extends over very few sections, and they represent two of the four thickenings out of which the aortic and semilunar valves are formed, the other two being the primary thickenings at this level. It may also be noted that the spiral of the primary thickenings is a right spiral and that it extends through two right angles. That thickening which is ventral and to the left in A is dorsal and to the right in G, and further that which is dorsal and to the right in A is ventral and to the left in G. This degree of spiral winding is particularly interesting, and its significance will now be observed. Tracing the two lumina which will arise after fusion of the primary cushions, it will be clear, since the upgrowing interventricular septum eventually fuses with the septum X in G, that the pulmonary lumen will

become continuous with the right ventricle and the aortic with the left.

Dr. Ingalls,[3] in his account of the heart of the 4·9 mm. embryo, describes in detail the arrangement of the thickenings in this part of the tube, and in connexion with the foregoing its perusal is of much interest since there is about a week's difference in age between the two specimens. "The endothelial tube," he says, "is everywhere separated from the muscular wall, and where the latter joins the epithelium of the roof of the pericardial cavity the connective tissue cells situated between them and the endothelial tube continue into the mesenchyme of the gill arches. These cells, which originate from the endocardium, are regularly arranged around the endothelial tube, which is divided, as already mentioned, by a large interval from the thicker muscular tube. The latter has throughout a transversely oval form, the shape of which that of the inner tube is completely independent. The endothelial tube has cranially a corresponding form, but soon the more reduced connective tissue cells collect themselves together principally ventrally and dorsally. We follow now the truncus and bulbus caudalwards and we find that these little accumulations of cells gradually alter in position, and indeed the ventral goes towards the right and the dorsal towards the left, and corresponding to this the left end of the longer diameter of the tube turns itself also ventralwards. This twisting amounts on the whole to 180°." Piper, on the other hand, in the heart of the embryo 6–8 mm. describes the thickenings as having "from below upwards a left spiral course and describing $\frac{3}{4}$ of a complete rotation." A consideration of these various facts opens out certain problems to which brief reference may now be made.

1. *Right-handed and left-handed spirals.*—In the heart of the 7 mm. embryo the endocardial thickenings, as just stated, run a right spiral course, and the septum when formed and joined to the ventricular septum will divide the original single lumen into two, the anterior of which will communicate with the right ventricle and the posterior with the left. In other words, the pulmonary artery taking origin from the right ventricle will pass upwards in front of the aorta, pass round its left side, and terminate in a plane behind it, just as in the adult. If, on the other hand, the thickenings ran a left spiral course through 180 degrees, the two lumina, pulmonary and aortic, when formed, would terminate below in precisely the same way, the pulmonary communicating with the right ventricle and the aortic with the left. The essential difference in the two cases would be, that with the occurrence of the left-handed spiral the pulmonary artery arising from the right ventricle would pass upwards in front of the aorta, pass round its *right* side, and terminate in a plane behind it. The condition would, in fact, be like that found in the usual case of transposition of the heart, where there is *lateral* transposition of aorta and pulmonary artery.

Mr. Adrian Stokes[4] has recently published a very interesting account of an abnormal heart which was transposed. In his specimen, however, the aorta and pulmonary artery, instead of being *laterally* transposed were transposed *antero-posteriorly*, and he supports the view that this condition, in which the aorta is in front and the pulmonary artery behind, depends on the septum describing a left-handed instead of a right-handed spiral as it passes down to join the interventricular septum. From a consideration of the data derived from a study of the heart in the 7 mm. embryo and Ingalls's embryo it is difficult to see how the interchange is brought out by simply reversing the spiral. I think that an explanation based on an arrest of development which may take place at a certain stage fits in better with the embryological facts. This explanation may, however, be conveniently taken after the consideration of another important point in the ontogeny of the aortic end of the heart tube.

2. *Relationship of aortic and pulmonary lumina at level of semilunar valves.*—On examining Section C, Fig. 23, which is taken at the level of the semilunar valves, it will be seen that the aortic passage is in front and to the right, whilst the pulmonary passage is behind and to the left. Clearly, therefore, some further changes are necessary in order to bring them into their true relative positions as found in the adult.

Dr. A. Langer,[5] who has dealt with this subject very fully in birds, describes at the end of his paper the condition of affairs in a human embryo of 27–28 days, which closely agrees with the description given above. Moreover, he finds that in order to bring the aorta and pulmonary passages into their final positions a certain amount of torsion takes place at the upper part of the tube; and in a human embryo 8·5 mm. long, in the possession of Professor A. Robinson, which I have had an opportunity of examining, the torsion has proceeded to the extent that the pulmonary passage is in front and to the left. The further stages I have not so far had an opportunity of investigating, but reconstructions at the fifth and sixth weeks should definitely clear up the point. At any rate, an alteration in position must take place, and its nature is probably closely bound up with the changes taking place in the bulbus which lead to its incorporation with the right ventricle. These changes are possibly the result of unequal rates of growth.

In his Hunterian lectures, published in 1909, Professor Keith, from a study of abnormal hearts, arrived at the conclusion that there takes place during development an atrophy of the bulbar part of the primitive cardiac tube which brings the two orifices into their normal positions. The evidence of ontogenetic development as described above confirms the main fact embodied in that conclusion. The change which occurs, whether it be spoken of as a torsion or an atrophy, leading to the assumption of the normal position of aortic and pulmonary orifices is a definite feature in the march of events, and it will be interesting to see if further study of the developing heart in the first two weeks or so of the second month will demonstrate the nature of its cause.

3. *Suggested explanation of antero-posterior transposition of aorta and pulmonary artery based on the arrangement of parts at the end of the fourth week.*—In the usual form of antero-posterior transposition of the aorta and pulmonary artery, the latter arises behind the aorta from the left ventricle, while the aorta placed in front springs from the right ventricle. A much rarer form of transposition is that in which the aorta and pulmonary artery spring from the left and right ventricles respectively, as in the normal heart, whilst at their origin they are transposed antero-posteriorly. In situs inversus the heart may or may not exhibit antero-posterior transposition of the great trunks.

Various explanations have been advanced by Rokitansky, Max Mann, Keith, and Stokes, amongst others, to account for these puzzling conditions, in which there is one feature in common, and that is a transposition, in the antero-posterior direction, of the aorta and pulmonary artery. According to Keith, the condition is brought about by a reversal of those processes in the bulbus cordis which lead to the normal arrangement, whilst Stokes finds the clue to the problem in a reversal of the spiral septum in the bulb. On the other hand, both Rokitansky and Mann believe that the aortic end of the heart in these cases undergoes an abnormal degree of rotation.

The explanation which I venture to put forward is based on the relationship which exists between the aortic and pulmonary passages in the heart of the 7 mm. embryo, and the assumption that arrest of development may take place at this stage. The relationship is just the one which is found in transposition. The aorta is in front and to the right of the pulmonary artery, the position of the aortic cusps is reversed, the non-coronary cusp being ventral and to the right. If it be assumed, further, that below the valves the septum is not formed, then the anterior passage would lie over the right half of the ventricle and the posterior over the left. If the septum be present, however, then the anterior passage must go to the left and the posterior to the right ventricle.

It is well known that in many of these cases of transposition the interventricular septum is feebly developed, or if it is formed, that an interventricular foramen frequently persists. The explanation suggested above seems applicable mainly to this type of case, in which there has been absence of development, or faulty development, of the part of the spiral septum below the semilunar valves.

A CONTRIBUTION TO THE STUDY OF THE INFLUENCES DETERMINING THE PREVALENCE OF BOVINE TUBERCULOUS MASTITIS.[1]

BY SHERIDAN DELÉPINE, M.B., C.M. EDIN.,

PROFESSOR OF COMPARATIVE PATHOLOGY AND BACTERIOLOGY AND DIRECTOR, PUBLIC HEALTH LABORATORY, VICTORIA UNIVERSITY, MANCHESTER.

1. *Introduction.*

IN studying the mode of spread of any infectious disease it is always necessary to keep in mind the complexity of the conditions influencing or determining the occurrence of infection. To the pathologist an infectious disease is invariably the result of the action of an invading or parasitic organism upon an invaded organism or host.

The occurrence of a case of "tuberculosis vera" may be taken as absolute proof that Koch's bacillus has penetrated and multiplied in the tissues of an individual in whom it has caused the symptoms and lesions which we associate with tuberculosis. The converse is not true, and we cannot say that the presence of tubercle bacilli in a locality, or even within the body of an individual, is invariably followed by the production of tuberculosis. This sequence is probably the exception. The occurrence of cases of infectious disease is not determined only by the presence of the essential causal agent, but also by the coöperative agency of various factors, some of which become, under certain circumstances, so important that they more or less completely overshadow the essential cause. This is particularly noticeable in the case of diseases such as tuberculosis, which are caused by widely-distributed microbes. If, whenever the opportunity of infection occurred, the bacillus were abundant or virulent enough, and its possible victims were in a receptive state, there would be very few persons free from tuberculosis among civilised communities.

The importance of predisposing factors is often so great that not a few clinicians and administrators have given scant attention to the essential cause. It must be acknowledged that in many cases it is possible to obtain excellent results by dealing thoroughly with predisposing causes, and often there is no other course open to us. It is, however, never safe to disregard, even temporarily or partially, the *causa causans*, because it is a variable factor, and may, under the influence of various circumstances, increase in amount or acquire infective powers exceeding the average. Neither is it safe to trust entirely the action of natural or artificial curative agencies. Recoveries from infectious diseases may be apparent or real, and do not invariably result in so great a reduction in the number of infective centres as might be expected. Recoveries brought about by natural processes introduce also an additional element of complexity in our estimates of the incidence of various infectious diseases.

In studying the conditions which influence the prevalence of any infectious disease we must therefore take account of the possible action of a great number of factors which may roughly be grouped into the following categories: The distribution and habits of the infecting parasite, the conditions influencing the quantity of the parasite, the conditions influencing the virulence of the parasite, the opportunities and channels of infection, the conditions influencing the resistance of the possible host, and the proportion and completeness of recoveries.

I have thought it necessary to make these few preliminary, and I might almost say commonplace, remarks to make it clear that I have no illusion regarding the completeness of the facts upon which this communication is based. I must also at this stage explain that it is not my intention to enter upon a discussion of the relations of bovine to human tuberculosis. I am fully convinced of the unity of human and bovine tuberculosis—a unity which does not preclude variations. I believe that, both in man and cattle, infected food is an important conveyer of tuberculous infection, and that the milk of cows suffering from tuberculous mastitis is the most important means of transmission of bovine tuberculosis to the infant.

[1] A paper read before the Epidemiological Section of the Royal Society of Medicine on April 22nd, 1910.

2. *Tuberculosis of the Udder in Relation to Tuberculosis of other Organs.*

Cows affected with tuberculosis of the udder are, in the majority of cases, suffering also from more or less advanced tuberculosis of other organs. I have personally examined post mortem the organs of a great number of cows affected with tuberculous mastitis, and in only one case out of nearly 100 have I failed to discover tuberculous lesions of internal organs. In three more cases out of the same number the internal lesions were limited; in the great majority of cases they were extensive. Out of more than 300 cows suffering from tuberculosis of the udder, and examined by several veterinary surgeons, only four have been reported to me as having been free from any other tuberculous lesions. Primary tuberculosis of the cow's udder would therefore appear to be of rare occurrence.

Tuberculous mastitis is not common in young cows. I estimate that about 90 per cent. of the animals suffering from this lesion are middle-aged or old cows—i.e., cows over four or five years of age. I regret not to be able to give more definite information on this point, which is not without importance; but, in the absence of any regular system of registration and inspection of cows, it is practically impossible for a veterinary surgeon to ascertain the exact age of all the cows inspected by him during an occasional visit to a farm. An experienced man can, however, estimate rapidly and fairly accurately whether a cow is young or old. It is mostly upon data gathered in this way, more especially by Mr. J. W. Brittlebank, whose experience in such matters is well known, that my opinion regarding the age of cows is based.

From personal observations made between the years 1896 and 1898 I came to the conclusion that in about 3·7 per cent. of all cows suffering from tuberculosis of any organ the udder was affected with tuberculosis.[2] This estimate was rather higher than those made at the time by three well-known veterinary authorities, but subsequent experience has shown me that even my estimate was barely high enough. It may therefore be safely assumed that for each cow affected with tuberculous mastitis there are on an average about 27 cows with tuberculous lesions of other organs. From the facts collected in this brief summary it seems reasonable to infer, (1) that the presence of a tuberculous udder on a farm is in the great majority of cases evidence that there is on that farm at least one cow suffering with advanced, or fairly advanced, tuberculosis; and (2) that the number of cows found affected with tuberculosis of the udder in a district may be taken as a rough index of the probable number of tuberculous cows in that district.

A study of the conditions influencing the prevalence of tuberculous mastitis has therefore distinct bearing upon the whole problem of bovine tuberculosis. The importance of this conclusion depends on the facts: (1) that tuberculous mastitis can, by bacteriological methods, be diagnosed with great accuracy; (2) that no other accurate method is at present available for estimating approximately the relative prevalence of bovine tuberculosis in the various parts of any extensive area; and (3) that, through the work done in Manchester, we are now in possession of a large mass of reliable data regarding the incidence of tuberculous mastitis.

If systematic tuberculin testing of all cattle could be practised it would be easy, in a comparatively short time, to obtain more complete data, notwithstanding the fact that the tuberculin reaction often fails in old cattle suffering from advanced tuberculosis; but this simple method was not available 14 years ago, when I began this investigation.

The testing of milk for the presence of tubercle bacilli, though it does not indicate directly the total number of tuberculous animals, has an advantage over the tuberculin test in that it reveals the cows that are the most dangerous to human health.

3. *Collection of Data; Examination of Samples of Milk; Inspection of Cows and Sheds.*

A short statement of the manner in which the Manchester Milk Clauses (1899) have been administered under Dr. James Niven's direction during the last eleven years will make clear the nature of the evidence upon which my statistics are based.

Samples of cows' milk are taken by the food and drugs inspector from the milk-cans on their arrival at the railway stations or elsewhere within the city. Each milk-can

[2] "Prevention of Tuberculosis in Cattle," Veterinarian, July and August, 1899.

contains the milk of several cows, and for this reason the milk obtained from it is termed "mixed milk." The source of each of these samples is carefully recorded. They are submitted to microscopical examination and tested by inoculation. The farms supplying milk found capable of producing tuberculosis are inspected; the cows are examined by the veterinary inspector, who takes a sample of milk from each udder that appears to him diseased and possibly affected with tuberculosis. These samples of unmixed milk are tested bacteriologically, and when any is found capable of producing tuberculosis this is taken as a proof that the corresponding cow is secreting tuberculous milk, and that it is in all probability suffering from tuberculous mastitis. The farmer is required by the medical officer of health to isolate the cow or cows producing tuberculous milk, and at the same time he is advised to have the animal slaughtered in the presence of the veterinary inspector. As this advice is followed in the majority of cases, opportunity is afforded to verify the accuracy of the bacteriological finding, and an important source of infection is removed.

With the sanction of the Health Committee I had from the first certain information relating to each farm and to each cow dealt with entered on forms which I provided for that purpose. Dr. Niven has kindly furnished me with additional data whenever it was possible for him to do so, and with his sanction I have also obtained from Mr. Brittlebank valuable information regarding the state of the inspected cows and cowsheds, and the exact position of the farms which were not clearly indicated on the ordnance map. As a detailed account of my methods and results has recently appeared in the Thirty-Eighth Annual Report of the Local Government Board,[3] it would not serve any useful purpose to burden this communication with similar details. This report—the scope of which was indicated to me by Dr. Arthur Newsholme—contains an account of: (1) Experiments which I made between the years 1892 and 1908; (2) methods which I devised before 1895 for administrative purposes; (3) the results of the examination, for various sanitary authorities, of 7000 samples of milk, carried out in my laboratory between the years 1896 and 1908; (4) the sources of the tubercle bacilli found in the milk examined; and (5) the distribution of the farms supplying tuberculous milk. Some details not included in the above report are given in another paper which I read last November before the Manchester Statistical Society.[4]

For the present purpose it will be sufficient to reproduce here tabulated statements of the results obtained in connexion with the Manchester milk-supply only. In the following tables I have brought up to date the returns published in the report and communication mentioned above by the addition of the figures relating to the years 1908 and 1909:—

TABLE I.—*Samples of Mixed Milk Collected in Manchester during the Years 1896 to 1909 inclusive.*

Years of collection.	Total number of samples tested for tubercle bacilli by inoculation.	Samples found to be capable of producing tuberculosis by inoculation.	
		Actual number.	Percentage.
Three years, 1896-99*	110	19	17·2
1900	358	40	11·1
1901	440	43	9·7
1902	424	38	8·9
1903	430	51	11·8
1904	425	43	10·1
1905	757	60	7·9
1906	704	47	6·6
Three years 1907	722	43	5·7
Three years 1908	341	30	8·9
Three years 1909	649	36	5·7
Three years (1907–1909)	1712	109	6·36
Totals, 1896–1909	5360	450	8·3

* No mixed samples taken in 1899.

This table shows that, up to the end of the year 1909, 5360 cans of mixed milk sent to Manchester were sampled on their arrival, and that 450 of these cans were found to contain tuberculous milk. This makes an average of 8·3 per cent. for the whole period.

TABLE II.—*Samples of Unmixed Milk Obtained by the Veterinary Inspector from Cows the Udders of which appeared to him to be Possibly Affected with Tuberculosis.**

Years of collection.	Total number of cows tested.	Number of cows affected with tuberculous mastitis.	
		Actual number.	Percentage.
1896–98	29	5	17·2
1899	19	3	15·7
1900	142	31	21·8
1901	166	34	20·4
1902	95	32	33·6
1903	68	28	41·1
1904	85	18	21·1
1905	108	28	25·9
1906	125	33	26·4
1907	100	30	30·0
1908	74	26	35·1
1909	71	22	38·0
Totals, 1896–1909	1082	290	26·8

* These cows were all on farms from which tuberculous milk had been sent to Manchester.

This table shows that up to the end of 1909 the udders of 1082 cows, among those that had been examined clinically by the veterinary surgeon, showed signs of being possibly affected with tuberculosis, and that of these 1082 udders 290 were proved to be capable of producing tuberculosis in guinea-pigs by inoculation.

TABLE III.—*Number of Farms Tested each Year, with Number of Farms sending Tuberculous Milk to Manchester.*

Years.	Farms tested for the first time.			Farms retested.		
	Total number tested.	Number found tuberculous.		Total number.	Number found tuberculous.	
		Actual number.	Percentage.		Actual number.	Percentage.
1896–1900	427	72	16·8	—	—	—
1901	161	16	9·9	207	28	13·5
1902	131	18	13·8	217	23	10·5
1903	109	12	11·0	230	32	13·9
1904	111	12	10·8	220	26	11·7
1905	209	15	7·1	362	33	9·1
1906	145	9	6·2	410	39	9·5
1907	92	5	5·4	457	35	7·6
1908	60	4	6·6	218	24	11·0
1909	168	13	7·7	446	25	5·6
Totals...	1613	176	10·9	2763	238	8·6

1613 farms were therefore among them tested 4382 times, and were found on 414 occasions to supply tuberculous milk. In the group of farms retested are included farms which were not found tuberculous when first tested, but were found tuberculous afterwards.

Tables I., II., and III. are of great interest from an administrative point of view. Table I. shows that in the three years 1896 to 1899 (exclusive) 17·2 per cent. of the cans of milk arriving in Manchester contained tuberculous milk capable of infecting experimental animals, and that the average for the three years ending with the year 1909 had been reduced to 6·36 per cent. This result had been in great part obtained by the removal from the herds supplying Manchester of some 290 cows (Table II.) proved by bacteriological examination to be suffering from tuberculosis of the udder and by sanitary measures promoting the health

[3] Supplement containing the Report of the Medical Officer for 1908–09, pp. 341 to 414.

[4] The Manchester Milk-supply from a Public Health Point of View, November, 1909.

of the cows. The effect of these measures is also indicated in Table III., which shows that the number of farms supplying tuberculous milk is now less than half of what it was in 1900. In order to find out whether this improvement was not attributable to influences other than the active supervision exercised by the Manchester authority I selected three quite separate districts, situated respectively in the northern, eastern, and southern parts of the area from which Manchester obtains milk. I then compared the frequency of tuberculous infection of the milk sent from the farms in each of these districts to Manchester and of the milk sent from neighbouring farms situated in the same districts to other towns. All the samples of milk used for this comparison having been collected according to the same methods, and examined in my laboratory during the same period, the results are strictly comparable. The results are summed up in the following short table:—

TABLE IV.—*Comparison of the Results of the Examination of 745 Samples of Mixed Milk supplied respectively to Manchester and Four other Towns during the Years 1906 and 1907, and obtained from Farms situated in Three Different Districts.*

Districts in which the farms supplying the milk examined are situated.	Proportion of tuberculous milk supplied to each town (1906-7).						
	Manchester.			Town A, 49 samples.	Town B, 84 samples.	Town C, 69 samples.	Town D, 73 samples.
	111 samples	194 samples	165 samples				
	%	%	%	%	%	%	%
Northern district	3·6	—	—	4·0	—	—	—
Eastern district	—	4·6	—	—	11·9	8·6	—
Southern district	—	—	7·2	—	—	—	13·7

It will be noticed that in each case the proportion of tuberculous milk reaching Manchester was materially less than that reaching other towns, notwithstanding the fact that originally the milk sent to Manchester from the same districts was infected even to a greater extent than the milk supplied to the four other towns during the years 1906 and 1907. It is also clear that the cows kept respectively in the northern, western, and southern districts were very unequally affected with tuberculosis.

The results recorded in Tables I. to IV. show clearly that the skilful administration of the Manchester Milk Clauses by Dr. Niven has brought about a very great improvement in the Manchester milk-supply. It is not, however, with this aspect of the question that the present communication is concerned, but with the indications which the figures previously quoted supply regarding the distribution of tuberculosis. They indicate clearly (1) that various districts are very unequally infected with tuberculosis; (2) that bovine tuberculosis is preventable to a very material extent; and (3) that at least some of the conditions against which preventive measures have been directed are of importance in relation to the prevalence of bovine tuberculosis.

4. *Proportion of Tuberculous Farms in Various Regions.*

For the purpose of ascertaining the distribution of tuberculous farms in the region dealt with I have prepared a map in which the position of each of the farms that have been tested between 1896 and 1909 is indicated. I have subdivided this map, which is based upon the "one-inch-to-the-mile" ordnance map, into one-square-mile areas. These geometrical areas are much more convenient for this kind of investigation than the larger and unequal areas corresponding to administrative districts, the shape of which is also too irregular to allow of accurate comparison being made. The *one-square-mile* areas are grouped in one-mile-broad *longitudinal zones*, numbered consecutively from west to east, and in one-mile-broad *latitudinal zones*, numbered from north to south. The exact position of each one-square-mile area may therefore be accurately determined by two numbers. To facilitate reference I have grouped the longitudinal zones into four-mile-broad zones, each of which is designated by a capital letter. The latitudinal zones are grouped in the same way, and each four-mile-broad latitudinal zone is numbered with a Roman numeral.

The position of each of the tested farms was spotted on this map. The position of the farms which were not indicated by name in the ordnance map has been determined with the assistance of Mr. Brittlebank, whose intimate knowledge of the various districts under consideration has been of very great value to me. Notwithstanding the trouble taken to indicate as accurately as possible the position of the farms not shown in the ordnance map, it was obviously impossible to avoid a certain amount of error; this probably does not exceed quarter of a mile, and in the great majority of cases is much less. In this spot map all the farms tested or inspected between 1896 and 1909 which have been found tuberculous at one time or another during the 13 years are indicated.

In summing up the facts brought out by this map I will avoid any reference to the political divisions of the areas under investigation, as this would serve no useful purpose, and might, as it has done on a previous occasion, give rise to unnecessary annoyance and misconception.

In Table V. the situation of the various districts is indicated by the letters and numerals corresponding respectively to the longitudinal and latitudinal four-mile zones. It does not include 89 farms which were tested between June, 1909, and December, 1909. The addition of these 89 farms brings the total of inspected farms to 1613, of which 344, or 21·3 per cent., have at one time or another during the last 13 years been found to produce tuberculous milk. The addition of the 89 farms does not alter the percentage previously arrived at.

* Several of these farms were inspected, primarily, in new districts.

Table V. brings out clearly the very unequal distribution of tuberculosis of the udder. To obtain comparable numbers

of farms I have, where necessary, grouped together adjacent zones. The effect of this is to reduce the contrast between the best and the worst districts, but, as all the farms in each district have not been tested, this obliteration of excessive contrasts tends to make the figures more reliable. Manchester is included in the latitudinal Zones XVII. and XVIII.; nearly all the farms in that zone are situated either within the town boundary or in the neighbourhood of the town. On nearly 16 per cent. of these farms cows with tuberculous udders have at one time or another been found.

In the sixteen-mile-broad group of Zones IX., X., XI., and XII. (north of Manchester) the percentage was ...	10·5
In the twenty-mile-broad group of Zones XIII., XIV., XV., XVI., and XVII. (south of the latter and including the northern half of the town) the percentage was ...	14·7
In Zones XVIII. and XIX., eight miles broad (including the southern half of Manchester) the percentage was ...	17·8
In Zone XX. the percentage was	22·7
„ XXI. „ „	23·9
„ XXII. „ „	29·7
„ XXIII. „ „	24·3
„ XXIV. „ „	14·9
„ XXV. „ „	16·8
„ XXVI. „ „	22·5
In Zones XXVII., XXVIII., XXIX., XXX., and XXXI. the percentage was	16·6

In attempting to discover the causes which have brought about this unequal distribution it is necessary to consider the possible influence of a number of factors. The area under consideration is not extensive enough to allow of such marked climatic differences as might reasonably be expected to have brought about the unequal distribution of the disease. There is no obvious relation between the distribution of the disease and the geological features of the various districts. I have not, however, analysed yet the facts sufficiently fully to be in a position to express a final opinion upon this point. With regard to the topography of the area there is one coincidence which at once calls for notice. A great part of the land in the region south of Manchester, where tuberculosis was very prevalent, is distinctly at a lower level, on an average, than the northern regions, where tuberculosis was less prevalent. The spot map shows, however, that there are several high-level districts that are much affected, and many low-lying districts where farms are comparatively free from infection.

5. *Influence of Altitude and of Vicinity of Rivers.*

To study the influence of altitude and other physical features of the land, I have prepared a map of Lancashire and Cheshire in which the rivers, and the 300-feet and the 1000-feet contour lines are shown. These data are sufficient to indicate broadly the elevation and configuration of the surface of the land in most of the districts in which the farms are situated. The course of the rivers in the lowest regions may be taken to indicate the parts where excessive dampness may be expected. On the same map I have indicated in each square-mile area the number of farms tested, and the number of those which have been found tuberculous at one time or another between 1896 and 1909. This map shows, therefore, the proportion of farms that have been found tuberculous out of the total number examined in each square-mile area, and at the same time the altitude in each area and its relation to streams.

The information obtainable from this map is summed up in Table VI., according to the same plan as the general results of the inspection of farms have been tabulated in Table V. The number of farms included in Table VI. is smaller than in Table V., because the second map takes up only the western slopes of the Pennine Chain in the regions corresponding to Lancashire and Cheshire, it includes an area containing 1234 farms out of a total of 1613 tested up to the end of December, 1909. The percentage of farms found tuberculous in the total area and in the area shown in the map is as follows: Total area, 1613 farms, of which 344 were tuberculous, or 21·3 per cent.; area included in the second map, 1234 farms, of which 271 were tuberculous, or 21·9 per cent. It is therefore probable that the selected area shown represents fairly the total area. The advantage of selecting the western slopes of the Pennine Range is that all that region is exposed to very similar climatic conditions. A comparison of Tables V. and VI. leads one to the conclusion

TABLE VI.—*Proportion of Tuberculous Farms in Various Zones and at Various Altitudes. The Zones are grouped in this Table in the same way as in Table V.*

After excluding groups of less than 10 farms	Maxima ...	—	45·4	—	40·0	—	30·0	—	23·2	—
	Minima ...	—	6·0	—	10·0	—	9·0	—	7·4	—

that the greater prevalence of bovine tuberculosis in the districts situated south of Manchester cannot be due only to the effects of difference of altitude or of the dampness of the soil attributable to the neighbourhood of rivers. The average percentage of tuberculous farms was:—

On or near the banks of rivers	22·7
On lands at a level not exceeding 300 feet	26·2
On lands at a level of 300 feet	20·8
On lands at a level of 300 to 1000 feet	19·2

The differences between the extremes of this series are small compared with the difference between 10·5 per cent. in northern Lancashire and the adjacent Yorkshire districts, and 29·7 per cent. in a region south of Manchester. The farms situated above the 300-feet line are apparently less liable to tuberculosis than the farms situated below that line, but the difference between 21·3 per cent. and 19·2 per cent., which indicate respectively the average number of tuberculous farms for the whole area and for the farms situated on high grounds, is not very great. A closer examination of the results recorded in Table VI. shows still more clearly that the influence of the difference of altitude under consideration is not a dominant factor. If one excludes from consideration the groups consisting of less than ten farms, it will be found that in each altitude there are groups that are comparatively free, while others are extensively affected. The differences between the minima and the maxima relating to each altitude are considerable. Thus, the least affected group of farms (6 per cent.) is found among those situated near the banks of rivers, but in the same category is also found the group showing the highest percentage of tuberculous farms—45·4. The same contrasts are observed in all categories. It is interesting to note that the maxima indicate the same tendency to improvement as the altitude increases as is shown by the averages. It is, however, quite clear that some more powerful influence than that of situation must be found to explain the great differences which I have indicated.

6. *Influence of the State of the Cowshed and Herds.*

Much has been said of the share taken in the spread of tuberculosis by badly constructed, small, ill-ventilated, and otherwise insanitary shippons, of the liability to tuberculosis of certain breeds of cattle, of the pernicious influence of "close breeding for high milking," of the effects of heredity, &c. Although very strong opinions have been expressed by practical and other men upon each of these points, it is difficult, not to say impossible, to discover any *satisfactory record of facts* in their support.

In the hope of obtaining more definite information I asked Mr. Brittlebank to give me certain particulars regarding some 400 farms inspected by him. The particulars asked for were the following. State, age, construction, sanitation, cubic capacity, ventilation, cleanliness of cowshed; number of cows kept; how much kept in the open; special breed; state of cows; how long kept on the farm; average age; stability of stock; precautions taken to avoid the introduction of diseased animals; arrangements for dealing with diseased animals and preventing the spread of disease.

I was aware of the difficulty of obtaining definite or accurate answers to many of the questions included in my schedule, but I thought it desirable to ascertain to what an extent attention was paid to the various conditions which might affect the health of the cattle. It may at once be said that several of my questions remained unanswered for the simple reason that they referred to matters which, generally speaking, had not received proper attention from the farmer. Thus there is no evidence that, apart from reliance on general appearances and judgment based upon practical experience, farmers adopt, as a rule, any *reliable method to avoid the introduction of diseased animals among their herds*, or that they make, of their own accord, *systematic provision for the isolation or disposal of tuberculous animals*. It appears also difficult to obtain very reliable information with regard to the *average age or stability of stock;* this information would have been easily obtained if farmers generally made it a practice to replace animals that had reached a certain age. Very little information capable of forming a reliable basis for generalisation could be obtained regarding the *amount of outdoor life* allowed to cattle in various districts. On some farms cattle are kept in the open as much as possible, but I have so little information regarding the majority of farms that it is not possible to estimate how far the practice influences the incidence of tuberculosis. The keeping of cows in the open all the summer and whenever the weather permits is certainly not sufficient to prevent the occurrence of tuberculosis, for I have clear statements regarding ten farms where the practice was adopted, and in seven of these farms tuberculosis of the udder was observed. On two of these tuberculosis of the udder was detected twice. There were altogether 125 cows on these seven tuberculous farms, and among these cows eight cases of tuberculous mastitis were clearly demonstrated; two probable cases escaped detection. Of these seven farms, three were quite satisfactory from a sanitary point of view, one was moderately good, and three were bad.

With regard to the *breed*, there is nothing in the evidence at my disposal indicating that the prevalence of tuberculosis in any district had any relation to the breed of cattle. On the great majority of farms all through the area the herds were composed of animals of various breeds.

In the case of 26 tuberculous farms there is a clear statement that the whole or part of the cattle were *home bred*. This is sufficient to prove that the practice is not uncommon, but I have no means of ascertaining whether there was any difference in that respect between tuberculous and non-tuberculous farms. With regard to the *general state of shippons*, their *ventilation* and *cleanliness*, the *general state of the cows*, and their *approximate age*, I have somewhat more complete information. In most cases this information is in the form of an expression of opinion, but, the opinion being that of an experienced veterinary surgeon (Mr. Brittlebank), and generally based on repeated inspection, it is probably more reliable than records of figures collected by less reliable observers. Moreover, it was only after obtaining the whole of the information about farms, not arranged in any definite order, that I classified all the facts, so that no preconceived idea could have materially influenced the record.

Out of 397 schedules relating to an equal number of farms I had to exclude 12 which were too incomplete to be of any use. This left 385 farms available for the purpose of the investigation. Of the 9283 cows on these farms, 1017 have been found to show some evidence or other of abnormal conditions of the udder, and 287 have been proved to be actually suffering from tuberculous mastitis. These results refer to the years 1896 to 1909, during which each of the 397 farms has been inspected more or less continuously during periods ranging from two to 12 years.[5]

In estimating the proportion of infected animals it is important to keep in mind the fact that during a period of 12 years the dairy stock of many farms had been entirely renewed. Even in the case of farms which have been inspected during shorter periods it is probable that the composition of the stock was not exactly the same at the beginning as at the end of the period. This want of stability, and the different practices adopted with regard to the renewal of old stock, make it impossible to estimate exactly the case incidence of tuberculous mastitis. The estimate of the proportion of infected farms is not vitiated to the same extent by the movements of the stock, although it is obvious that the chances of infection by the occasional introduction of tuberculous animals are increased when animals are frequently bought and sold. On the other hand, it is well to remember that when cows are allowed to age on an infected farm the proportion of tuberculous animals increases with the age of the stock.

I have published elsewhere statistics relating to several herds in which I found that less than 50 per cent. of the cows under five years were affected with tuberculosis, while more than 50 per cent. of the cows above five years of age were affected with tuberculosis. These statistics were based upon the results of the testing of 362 cows with tuberculin, confirmed by post-mortem examination in every case.[6] Whatever may be the disturbing influences of these various irregularities, it is obvious that if the situation of the farm, the state of the shippon, and the general condition of the animals, have a material influence upon the prevalence of tuberculosis, this should appear clearly when the characters

[5] The periods during which the farms were inspected are as follows: 1 to 2 years, 153 farms; 3 to 4 years, 81; 5 to 6 years, 49; 7 to 8 years, 56; 9 to 10 years, 41; and 11 to 12 years, 17—giving a total of 397 farms.

[6] Report of the Medical Officer to the Local Government Board, 1908-09, pp. 408-9.

of the farms which have been found free from tuberculosis are compared with those of the tuberculous farms.

To facilitate this comparison I have tabulated the information at my disposal as follows. I have divided all the farms into two groups: (*a*) Farms on which no tuberculous udders have been found; and (*b*) farms where tuberculous udders have been found. The farms (77) included in Group *A*, not being sufficiently numerous for subdivision into many latitudinal groups, have been divided into two divisions, the first corresponding to latitudinal Zones III. to XIX., and including the Manchester farms with the exception of the suburban farms on the south of the city. The second division corresponds to latitudinal Zones XX. to XXXI., and includes all the farms situated south of Manchester. The number of farms (385) included in Group *B* was large enough to be subdivided into five divisions. The first division of this group (III. to XIX.) corresponds exactly to the first division of Group *A*, and includes all the Manchester farms and those situated north of Manchester. It also corresponds to the three upper divisions in Table VI. The other four divisions correspond to the nine lower divisions in Table VI., and comprise all the farms south of Manchester, including the southern suburban farms. The data relating to the farms situated in each of the divisions are classified as follows:—

(I.) *State of the cowshed* as indicated by (1) general condition of the buildings; (2) cubic space and ventilation under the head of ventilation; (3) cleanliness.

(II.) *State of the cows:* (1) approximate age; (2) general health and nutrition, generally spoken of as condition of the animals.

(III.) *Number of cows* on the farm.

(IV.) *Number of cows showing some sign of disease of the udder.*

(V.) *Number of cows proved to be affected with tuberculous mastitis.*

In order to indicate the state of the shippon and of the stock, I adopted the following device. The state of things recorded under each question in the schedules was classified under three heads: (1) Very good, good, or satisfactory; (2) fair, moderate, or indifferent; (3) very bad, bad, unsatisfactory, or poor. This classification was not practicable with regard to the age, which I grouped as follows: Young or under 5; uncertain or middle-aged, or mixed when the proportion was not given; old, or over 8 years. Old does not, of course, mean that all the cows kept in the shippon were old, but that many were.

Having thus ascertained for each category the proportion of shippons that were unsatisfactory or bad beyond doubt, I found the proportion existing between these unsatisfactory shippons and the total number of shippons available for the study of each special feature. The shippons with regard to which I had no clear information, either good or bad, were excluded. The results of this part of the investigation are summarised in Table VII. Before proceeding to a discussion of the meaning of the facts recorded in Table VII., I must explain that the shippons included in the latitudinal Zones III. to XIX. in Groups *A* and *B* are almost all situated in Manchester or in the immediate neighbourhood of the town, and that they are those remaining after a great number of unsatisfactory shippons had been closed during the first years of the period under consideration. These farms are, therefore, selected farms; moreover, most of them have been improved under the supervision of the Health Department.

With the exception of some farms in Zone XX., very few of the other farms included in the table were so completely under the control of the authority. The contrast between the two classes of farms is well shown by the two Divisions III. to XIX. and XX. to XXXI., in Group *A* (non-tuberculous farms); the contrast is also evident when Division III. to XIX. is compared with the four Divisions XX. to XXXI. in Group *B* (tuberculous farms). The averages for *A* and *B* are distinctly affected by the improved state of these farms. An idea of their original state may, however, be gathered from the figures showing the number of cows, the udders of which were under suspicion when the farms were first examined.

TABLE VII.—*Relations between the State of the Shippon, the Condition and Number of Cows, and the Prevalence of Tuberculous Mastitis.*

(*C*) Farms belonging to various districts in which tuberculous udders were found more than once (twice in most cases)	III.–XXXI.	49	26	53	48	28	59	49	17	34	39	23	59	43	9	21	1164	23	259	22	75	6	—

* The figures given in these two columns refer only to the cases actually discovered. The proportion of cases of tuberculous mastitis detected in each group is given in Table V.

Some of the facts brought out by Table VII. may be summarised as follows:—

	Average state of farms and stock as indicated by the number of unsatisfactory shippons per cent. of the total available for comparison.	
	Shippons in which tuberculous udders were not found.	Shippons in which tuberculous udders were found.
Bad general condition of the building	37	56
Size and ventilation insufficient	34	62
Want of cleanliness	28	53
Many cows old	27	53
Bad condition of stock	13	21
Average number of cows with suspicious udders	5·6	12
Average number of cows with tuberculous udders...	0	3·7
Average number of cows per farm	20	25

It would appear from this that in every respect the shippons in which cows with tuberculous udders were found were worse than the others. But if, instead of comparing the averages only, one compares in each group the state of the tuberculous and non-tuberculous farms in various latitudinal zones, it becomes evident that the averages do not convey the whole truth, for if the non-tuberculous farms situated south of Manchester (Group A, Division XX. to XXXI.) are compared with the tuberculous farms also situated south of Manchester, one finds that the tuberculous farms in Zone III. to XIX., XX. to XXI., and XXII. are really more satisfactory than the non-tuberculous farms in Zone XX. to XXXI., and that it is only south of Zone XXII. that the tuberculous farms are worse in every respect than the non-tuberculous farms (not including the Manchester farms).

Another unexpected fact is obvious. Of the five divisions of tuberculous farms, the one corresponding to Zones XXIII. and XXIV. is undoubtedly the worst, while Division III. to XIX. is distinctly the best; but notwithstanding the considerable differences indicated in the table, the number of cows with tuberculous udders per cent. of the total number of cows is about the same in all the zones. The same may be said of the cows suspected of disease of the udder; there are slight differences, but these do not correspond in the least with the condition of the farms in the respective zones. I do not think that the differences in these percentages should be taken to indicate important differences in the incidence of tuberculosis, as they may possibly be the effect of the more frequent inspection of the proximal farms, which would almost certainly lead to the discovery of cases overlooked in the first visits. It is therefore clear that the condition of the farm, though important, is *not the dominant factor*, and that it is necessary to believe in the existence of some cause capable of overpowering the most favourable conditions, and practically independent of the most influential predisposing factors, to account for the focal distribution of cases of tuberculous mastitis.

7. *Actively and Potentially Infective Cases of Tuberculosis.*

A careful consideration of the statistical facts recorded in this paper, and of facts which I have observed in connexion with a number of farms that I have been able to study closely, has led me to the conclusion that cows in a state of advanced tuberculosis, and *emitting discharges loaded with tubercle bacilli*, constitute the chief factor determining the distribution of bovine tuberculosis. The number of cows suffering from tuberculosis is so great that there are very few farms that are entirely free from tuberculosis, but so long as the tuberculous lesions are confined to the serous membranes, bones, lymphatic glands, or viscera, and have not ulcerated, *they retain their bacilli*. Cows affected with these closed lesions, though potentially infective, are not important sources of infection. When, however, the disease has given rise to ulcerative lesions of the lungs, alimentary passages, genito-urinary passages, or udder, products containing tubercle bacilli are discharged by the animal, the surroundings of which become rapidly infected. As the disease advances there comes a stage when the quantity of tubercle bacilli so discharged is inconceivable. To obtain some information upon this point I have carefully watched a cow affected with pulmonary tuberculosis. For more than six months before its death it had a troublesome cough and at times expectorated some muco-purulent discharge; this was not, however, a conspicuous feature of the case. For four months the milk obtained from two quarters of its udder was loaded with tubercle bacilli, and during the first two out of these four months the supply was abundant. After a time a third quarter began to secrete tuberculous milk. One month before it was killed this cow begun to suffer from incoercible diarrhœa, which continued till its death. The quantity of fluid fæcal discharge evacuated by this cow was considerable, and yet almost every drop of this fluid was loaded with tubercle bacilli. The whole floor of the shippon was either covered or splashed over with this fluid, and, if I had not prevented it, the litter soaked with this tuberculous material would have been thrown upon the adjacent pasture land on which other cows were grazing. I have not measured exactly the amount of fluid fæces evacuated by this cow, but estimated roughly that the amount exceeded one gallon a day. It is easy to conceive how the presence of such a cow in a herd even for a period of a few weeks would be sufficient to infect both shippon and pastures to an extraordinary extent. In a well-kept farm such a cow would probably be isolated fairly early, but not before some mischief had been done. In a spacious, well-ventilated, clean shippon tuberculous discharges would probably not be allowed to accumulate and to contaminate to a very material extent the food or litter of the other cows. In a badly constructed, ill-ventilated, dirty shippon infection would be practically certain. But whether the shippon was clean or dirty it is probable that no precautions would be taken with regard to the litter and washings from the shippon, and that considerable quantities of manure would be infected by admixture with this material. Apart from this, the cow might infect pastures directly, and this infection would persist for a considerable time. It is generally known that desiccation or putrefaction does not affect the vitality or virulence of the tubercle bacillus for weeks and months. I have made an experiment which proves that seropurulent discharge from a tuberculous udder *kept for 19 months* (part of the time at the ordinary external temperature, but mostly at temperatures varying between − 4° C. and + 6° C.) was still virulent at the end of that period. This milk had been left in the bottle in which it had been originally collected, and it contained other bacteria than the tubercle bacillus. The tubercle bacilli had retained their usual characters and reactions, and their virulence was not very materially diminished. They gave rise to very extensive lesions in inoculated animals.

The extraordinary masses of bacilli which can be emitted by a cow in a state of actively infective tuberculosis, and the great resistance of the tubercle bacilli, whether they be contained in dry or moist products, are, I think, sufficient to explain the comparative independence of tuberculous infection from predisposing causes. I say comparative, because I do not wish it to be inferred that predisposing causes are without effect: I have given evidence to the contrary. I was so convinced in 1897 of the effects of infection of shippons and pastures by cases of advanced tuberculosis that in conducting the Ford Bank experiment[7] I began by eliminating all cases of advanced tuberculosis, separating from reacting cows all the animals that did not react with tuberculin, housing them in sheds that had been thoroughly disinfected, and not allowing these animals to graze in pastures that had already been used by tuberculous animals. New stock that had not yet passed the tuberculin test twice was not allowed to mix with these sound cows. In this way I cleared from tuberculosis a herd of 27 head of cattle in one year, and no fresh case occurred during a second year, although over 61 per cent. of the original stock were tuberculous. The same method has been used since under the supervision of Mr. Brittlebank at a large farm (129 cows) supplying milk to the hospitals under the Manchester corporation. This farm has now been kept free from tuberculosis for several years.

[7] The Stamping-out of Bovine Tuberculosis, Transactions of the British Congress on Tuberculosis, 1902.

I am convinced that the success of the work done by the Manchester sanitary committee for reducing the amount of tuberculous milk supplied to the town is mostly due to the removal of actively infective cows and to a diffusion of the knowledge of the danger connected with the keeping of diseased old cows.

8. *General Conclusions.*

The evidence analysed above, though incomplete, is, I believe, the best available at the present time for the purpose of estimating the causes of the unequal distribution of bovine tuberculosis. Notwithstanding the incompleteness of my data, I believe that certain conclusions can be based on them, and I think that anyone willing to take the trouble of considering fully the facts collected in this communication will find it difficult to come to other conclusions without neglecting some of the facts. If I am mistaken, there shall still remain to me the consoling thought that I have brought together a number of facts that cannot fail to prove useful to others interested in the prevention of tuberculosis.

There might be some justification for my taking this opportunity to insist once more upon the advisability of adopting the thorough measures which I have advocated during the last 14 years for stamping out bovine tuberculosis. I think, however, that it is undesirable to lengthen this communication.

The evidence obtained so far shows that bovine tuberculosis is, on an average, more prevalent in districts where shippons are generally in a bad state, small or badly ventilated and dirty, and where also it is the usual practice to retain many aged cows on the farms. It is, however, equally clear that there are districts where the farms exhibit all the defects above mentioned, and yet have remained free from tuberculous mastitis; on the other hand, there are districts in which the farms were free from these defects, and where many cases of tuberculous mastitis have been observed.

It does not therefore appear safe, under the present conditions, to rely chiefly upon ordinary sanitary measures for the purpose of controlling bovine tuberculosis. The frequent, partial or complete, failure of ordinary sanitary measures indicates that the action of the infective material is more or less independent of these measures, because it is at times either very abundant or very virulent. There was no reason to believe that the virulence of the tubercle bacillus was materially affected by the localities investigated, but I have shown that cows with ulcerating lesions—i.e., cows in the *actively infective stage* of tuberculosis—are capable of emitting, and do emit, an extraordinary number of tubercle bacilli. From this I am led to the conclusion that *bovine animals suffering from ulcerative tuberculous lesions, more especially of the respiratory organs, alimentary canal, genito-urinary organs and udder, constitute the chief factor determining the prevalence of bovine tuberculosis.* This conclusion indicates the great importance of *inspecting every animal*, of removing without delay all those that are actively infective, and of not allowing healthy animals to remain in places that have been infected, so long as these places have not been treated so as to remove as far as practicable the dangers of infection. All animals affected with tuberculosis are potentially dangerous, and as their age advances the chances of their becoming actively dangerous increases; it is therefore desirable, so long as bovine tuberculosis has not been stamped out, to reduce as much as possible the number of old animals.

I hardly need to attract your attention to the bearings which these conclusions have upon the control of human tuberculosis. The importance of the removal of infective cases of tuberculosis indicates the desirability of segregating cases of advanced tuberculosis.[8] These cases are generally actively infective, and I am inclined to believe that more could be done towards the future control of human tuberculosis by providing suitable homes for infective cases than by the treatment of early cases. Both things are good, but prevention would ultimately render treatment unnecessary and prevent an amount of suffering that treatment can only reduce. The provision of means of treatment should not interfere with the provision of means of prevention.

[8] "It is obvious that segregation is necessary only when patients are unable, owing to their circumstances or education, to understand and to observe the precautions which they must take to protect their neighbours. I need not say that I am not an advocate of harsh measures of segregation. I have previously advanced the same views in an address delivered before the North-Western Branch of the Society of Medical Officers of Health."—Public Health, April, 1899.

A CASE OF BLACKWATER FEVER.

BY D. G. MARSHALL, M.B., C.M. EDIN.,
MAJOR, I.M.S., RETIRED; LECTURER ON TROPICAL DISEASES IN THE UNIVERSITY OF EDINBURGH.

So many persons develop blackwater fever at home within a few days or months after returning from malarious countries, especially the West Coast of Africa, and the attacks so often supervene in out-of-the-way places, where practitioners have but few opportunities of treating tropical affections, that these notes, while presenting some points of interest to those specially engaged in the study of tropical diseases, may also prove useful to others unexpectedly called upon to treat a patient suffering from this disease.

On Jan. 7th, 1909, I was asked to see the case by a practitioner in Edinburgh, who had recognised its serious nature.

Previous history.—When first seen the patient was in too grave a condition to give a very clear account of his previous health, but since recovery he has furnished me with the necessary information. In 1907 he was appointed to the Colonial Medical Service and sent out to the West Coast of Africa, arriving there on Sept. 1st, 1907. Previous to this he had never been abroad. He commenced taking quinine in 10-grain doses as a prophylactic measure twice a week, though with some want of regularity. About six months after arrival he had a slight attack of malaria, which only lasted one day. This was followed by a similar attack in a fortnight and a third a few days later. After this he took 5 grains of quinine every day and was free from malaria during the remainder of his service in Africa.

The patient returned to England in September, 1908, and in about a fortnight discontinued taking quinine. In the month of November, while a student at the London School of Tropical Medicine, he suffered one day from feverish symptoms, and on examining his blood found a few ring forms of the malignant parasite. The next day he felt quite well and was able to resume work. He recommenced taking quinine and continued to do so for a month. The patient admits that at this time he was not wearing sufficient warm clothing.

On Dec. 29th, 1908, the patient came to Edinburgh, and during the following week attended various evening functions. The weather at this time was extremely cold, and on several occasions he experienced sensations of chill. On Jan. 6th, feeling all the symptoms of an impending attack of fever, he took a large dose of sulphate of quinine. At 9 P.M. he had a rigor, followed by another at 11 P.M. Shortly afterwards his urine was noticed to be of a dark port-wine colour. The temperature was 104° F. and the pulse 108. On the 7th (the second day) the temperature was 104° and the pulse 92. There was another severe rigor in the early morning. He complained of excessive nausea, there was occasional vomiting, and there were pains in the back. The urine was of port-wine colour; it contained no urobilin or bile pigments, but a few red corpuscles and granular casts were present. Spectroscopic examination showed the presence of methæmoglobin. On examination of the blood it was found that the red cells numbered 2,056,000 per cubic millimetre; the hæmoglobin was 46 per cent. The differential count of the leucocytes showed: polymorphs, 70 per cent.; small lymphocytes, 9 per cent.; and mononuclears, 21 per cent. Many transitional forms were seen. Long and careful examination failed to reveal the presence of malarial parasites. The red cells were normal in shape but were somewhat pale.

On Jan. 8th (the third day) the patient had passed a restless night. The temperature was 102° and the pulse 86. On the 9th (the fourth day) there had been continuous nausea and vomiting during the night. The patient looked very distressed, and the whole body surface was of a bright yellow colour. The temperature was 99° and the pulse 80, very weak. In the evening the temperature was normal and the pulse 80. No sickness had taken place since midday, and the urine was almost clear. On the 10th (the fifth day) the morning temperature was 99° and the pulse 80. The urine was again somewhat dark in colour. The evening temperature was 100°. On the 11th (the sixth day) the temperature was 99° and the pulse 86. The urine was of a clear straw colour.

On the 12th (the seventh day) it was noted that during the night the temperature rose to 101°, but the patient slept some hours. The blood count was as follows: white cells, 28,000 per cubic millimetre; polymorphs, 60 per cent.; lymphocytes, 27 per cent.; and mononuclears, 13 per cent. One megaloblast was seen. From this date he slowly improved. On the 25th (19 days after the onset) the red cells numbered 3,280,000 per cubic millimetre, and the hæmoglobin was 70 per cent. A differential count was practically normal. On Feb. 3rd, however, he complained of having spent a restless night, and the temperature was found to be 102°. Examination of the blood showed a few ring forms of the malignant parasite. Next day the temperature was normal, and he made a slow but perfect recovery. In a letter recently received he says: "My malaria must be cured, as I have not had any fever during the last 12 months."

Without entering into the vexed question of the etiology of this disease, it may be claimed that the case under notice is one of the many which show that residence in an unhealthy climate—with repeated serious attacks of malaria—is not a necessary condition in the causation of the disease; or to quote the words of Whipple,[1] "the amount of latent malaria has no relation to the disease." This patient was only in Africa one year, and the two or three attacks from which he suffered during this period were so slight that he never spent a whole day in bed.

Regarding the reputed influence of quinine in setting up an attack, it is to be noted that, having felt out of sorts for two or three days, during which time he was probably suffering from fever, the patient took a large dose of sulphate of quinine on Jan. 6th, and developed a high temperature with hæmoglobinuria in a few hours. On previous occasions the administration of quinine had cut short the attacks of fever, and it is impossible to avoid thinking that repeated chills and the large dose of quinine were the active agents in the production of hæmolysis.

Treatment.—To give or not to give quinine is a point on which there is much difference of opinion among those who, from their extensive knowledge of this affection, are well qualified to form an opinion. On the one hand are those who, believing the condition to be simply a severe form of malaria, advocate the administration of quinine in large doses throughout the attack. On the other hand are those who consider that in most cases quinine is the active agent in causing hæmolysis, and either abstain altogether from giving quinine or use it in very small doses.

The safest and most rational method of treatment is found between the two extremes, according to the following rules: 1. If malarial parasites are found in the blood quinine should be administered. 2. If the parasite is not found in the blood, or if there is any doubt, as, for example, where microscopic examination is impracticable, do not give quinine. Following these rules in the case under notice, as examination of the blood for the malarial parasite proved negative, quinine was withheld.

When, however, it is considered necessary to administer quinine there are certain important points to be considered. The first of these is the choice of a suitable preparation. It has been shown that the ordinary sulphate of quinine often produces hæmoglobinuria, and therefore it should never be used in this affection, the hydrobromate or di-hydrochloride being preferable.

Another point is the dosage. Some recommend large doses—10–15 grains repeated every four hours—but to avoid the possible danger of increasing the severity of the symptoms by these large doses it is better to administer it by the fractional method.

As above stated, this patient developed acute malaria 28 days after the onset of the blackwater fever. Parasites being present in the blood, quinine could not be withheld, but as it was considered the original large dose of sulphate of quinine had probably caused an injurious effect the hydrobromate was employed in fractional doses, 2 grains every two hours; by the next day the parasites had disappeared from the blood and the temperature was normal.

Setting aside the question of quinine, it is generally acknowledged that treatment must be directed to: (1) Flushing the blocked tubules of the kidney and promoting a satisfactory flow of urine; (2) treating other symptoms as they arise; and (3) maintaining the strength of the patient.

Past experience, and the results obtained by the latest research workers on this subject[2] show that the chief pathological condition in the kidney is a mechanical blocking of the tubules by the broken-down hæmoglobin thrown out of circulation. Clinically, suppression of urine is most to be feared. The rational treatment, then, is the one which was adopted in this case—e.g., allowing the patient to take large quantities of diluents—weak tea, coffee, milk with soda-water, &c.; in addition, Sternberg's mixture was used, and later weak solutions of boric acid.

A grave and distressing symptom is the persistent nausea and vomiting; in this case it was so severe that on the fourth day of the disease it appeared likely to bring about a fatal result. The ordinary methods of treatment—sinapisms, ice, champagne, &c.—had been used without the least benefit, but absolute relief was obtained within an hour by the application of liquor epispasticus over the line of the vagus in the left side of the neck. This method of treatment, which is frequently employed in tropical countries in cases of cholera, post chloroform sickness, and other conditions in which rapid and powerful counter-irritation of the vagus is desired, does not appear to have received at home the recognition it deserves. The results in my experience have been so highly satisfactory that I would strongly recommend it as worthy of trial in other forms of persistent vomiting which resist ordinary treatment.

To combat the tendency to heart failure, digitalis or strophanthus may be used, but caffeine and hypodermic injections of strychnine are to be preferred, and were employed in this case. Pain in the loins and hepatic region was relieved by the application of hot fomentations, while free action of the bowels was maintained by enemata and aperients. The disease is seldom associated with hyperpyrexia; in any case the use of antipyretics is to be avoided; and it has been recorded that on several occasions the administration of pilocarpine, with a view to promote diaphoresis, has been followed by a fatal result.

Prophylaxis.—Whatever views may be held regarding the active agents in the causation of this disease, it is generally acknowledged that "chill" is one of the most important factors. Most of the cases we see at home are found to be connected, as in this case, with the use of insufficient clothing. It is not surprising to find men who have previously suffered from malaria arriving at home during the winter from tropical countries, provided with only the lightest underwear, developing malaria or blackwater fever. It is the duty of all medical officers in tropical climates to give their patients advice on this point.

Should a person who has suffered from blackwater fever be permitted to return to a malarious country? This is a question which often demands the most serious consideration. An authority on this subject[3] has stated that, in his opinion, a man who has survived three attacks of this disease is practically immune (I have at present under treatment a man who has had two attacks in India), but as the all-round mortality is nearly 30 per cent. the chances of recovery from a second or third attack are so slight that, though in some cases where, for example, the livelihood of the patient absolutely demands it he may be allowed to run the risk, the rule should be that a person who has once suffered from blackwater fever should not remain in, or return to, a country where the disease is prevalent.

In the description of this case, detailed reference to the voluminous literature on the subject has been purposely avoided. Men working in tropical countries cannot overburden themselves with books; but at the same time they often ask to be furnished with information regarding the publications it is desirable for them to obtain. The two books to which reference has specially been made should be in the hands of all medical men practising in countries where blackwater fever is prevalent. Védy's monograph is a unique record of extensive clinical work; while in their book just published Barratt and Yorke give the results of a careful scientific investigation regarding the etiology of the disease.

DEATH FROM PERFORATION OF THE AORTA BY A HALFPENNY IMPACTED IN THE ŒSOPHAGUS.

WITH REMARKS ON SOME SIMILAR CASES.

BY G. GREY TURNER, F.R.C.S. ENG.,
ASSISTANT SURGEON, ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE.

THE patient was a boy, 4 years of age, the son of working people. On June 5th, 1906, he went to buy sweets with a halfpenny which his mother had given him, and while in the shop he startled the customers by shouting out that he had swallowed the coin. At the time efforts were made to recover it by the introduction of the fingers, making the child vomit, &c. Medical assistance was obtained, but the X rays were not employed, nor was any endeavour made to remove the coin by instrumentation. The fæces were carefully searched for a month without any sign of the coin, but it was, nevertheless, supposed to have been voided.

On the night of the accident, and for a day or two afterwards, the child complained of pain about the pit of the stomach, but this then disappeared and did not return either in that situation or elsewhere. For a couple of weeks afterwards the child had sore-throat and difficulty in swallowing, but this also gradually disappeared, although ever after the accident he had a tendency to regurgitate a bite or two with phlegm, though he usually took food without trouble. There was never any blood until the fatal illness. About the time that the dysphagia disappeared he began to be troubled with a severe cough and difficulty in breathing coming on in attacks during the day, though at night he rested very well. The cough was attributed to enlarged tonsils and weakness of the chest, especially as the child took cold very readily, but these troubles gradually diminished as the child got older.

This was the state of affairs up to April 15th, 1908, when the patient first began to vomit blood, just one year and ten months from the date of the accident. On that day (a Wednesday) the child had tea at 4 o'clock; at 6 P.M. he vomited a little blood; and about a quarter of an hour later brought up a large quantity of dark red blood. After this he turned very white but did not faint. On Thursday about 3 A.M. and again at 4 A.M. he vomited a further quantity of blood, but after this there was no vomiting until Friday at 3.45 A.M., when he brought up a small quantity. On this day, about noon, he was admitted to the Newcastle Infirmary. The child was absolutely blanched, the tissue being œdematous from loss of blood. A screen examination with the X rays plainly showed the coin lodged in the œsophagus, but as it was quite clear that some large vessel—almost certainly the aorta—had been opened by ulceration, no attempt was made to remove it. On Saturday the boy vomited blood several times and there was also melæna until death took place at 9 P.M.—i.e., just 75 hours after the first sign of hæmorrhage.

At the necropsy the coin was found impacted transversely just at the level of the crossing of the left bronchus. Both sides of the œsophagus were ulcerated where the edges of the coin impinged, and on the left this process had extended into the aorta just beyond the origin of the left subclavian. On the right wall the ulceration was not so deep and the mucous membrane was hypertrophied around about it. The aperture viewed from the aortic side appeared as a round hole just large enough to admit a pin and surrounded by a rim of organised fibrin. The œsophagus and stomach were occupied by a large mass of blood clot and there was evidence of the extensive hæmorrhage in the whole of the alimentary canal. The illustration shows the state of the parts as found at the post-mortem examination.

Remarks.—It seems curious that the coin should have given rise to so little difficulty in swallowing during its long sojourn in the œsophagus, for the child was able to take his ordinary food and was well nourished. But in other instances the same curious fact has been observed, and very shortly after the above case came under my notice a girl, aged 5 years, was sent to the infirmary from the same district with a halfpenny impacted in the œsophagus where it had lain for 25 days. The patient vomited several times on the day of the accident and twice on the following day, but after that her only symptom was blinking and watering of the eyes on swallowing hard food. This coin was easily removed through the mouth with the "catcher." A woman, aged 42 years, who swallowed a plate of false teeth was able to take her ordinary food for three days with little difficulty.

Judging by the experience of casualty work in large hospitals, impaction of foreign bodies in the œsophagus is comparatively common; but I doubt if the serious possibilities associated with them are sufficiently realised, for during the last six years no less than five cases have come under my notice in which death has been due to perforation of the aorta by foreign bodies.

The parts showing the œsophagus and cardiac end of the stomach laid open from behind. The coin is seen lodged transversely, a mass of blood-clot occupying the œsophagus below it. The smaller illustration shows the perforation from the aortic side, the actual hole being surrounded by a ring of organised fibrin giving it the appearance of a rosette.

In the first case a man, aged 54 years, died from hæmorrhage and septic mediastinitis five days after a meal of rabbit, and at the post-mortem examination one of the bones was found projecting into the lumen of the aorta.[1]

In the second case a man, aged 40 years, died from profuse hæmatemesis seven days after having partaken of rabbit, and the post-mortem examination disclosed a recent perforation between the œsophagus and the aorta, and although no bone was actually found the state of the parts left no room for doubt as to what had occurred.[2]

In the third case a sailor, 22 years of age, died on the road to the infirmary. A week previously a fish bone stuck in his throat. He complained of discomfort, but continued to work until the day before death when he first vomited blood. At the post-mortem examination a "hake bone" was found perforating the aorta in exactly the same situation as in the other cases.[3]

The fourth case was the boy the subject of this communication; while a fifth, due to the perforation of the

[2] Ibid., vol. vi., No. 5, February, 1906.
[3] Not published.

aorta by a fish bone, was reported by Sir T. Oliver in 1909.[4]

During the same period a man, aged 43 years, died after the removal of a plate of teeth by posterior mediastinal œsophagotomy,[5] and another in consequence of the impaction of a tooth-plate in the pharynx. During the last three years my colleagues, Mr. W. G. Richardson and Mr. J. W. Leech, together with myself have each had successful cases of œsophagotomy for the removal of impacted tooth-plates.

In the near future I feel sure that in cases of doubt the œsophagoscope will prove of immense value in the surgery of foreign bodies.

MODERN STATISTICAL METHODS.

BY JAMES MACDONALD TROUP, M.A. ST. AND., B.A., M.B., B.C. CANTAB.,
LATE EXAMINER IN MATHEMATICS, UNIVERSITIES OF ST. ANDREWS AND OF THE CAPE OF GOOD HOPE;
AND
G. DARELL MAYNARD, F.R.C.S. EDIN., M.R.C.S. ENG., L.R.C.P. LOND.,
MEDICAL OFFICER OF HEALTH, PRETORIA SUBURBS.

Introduction.

THE collection of facts and their systematic study is, and always must be, the foundation of every science. A man's experience, or clinical knowledge as it is called in medicine, consists in the observations which he has himself made, and is only of use to him in so far as the conclusions, consciously or unconsciously drawn, aid him in forming an opinion on a new set of phenomena when observed. In other words, he has observed the frequency with which one event is associated with another, and so judges the likelihood of a similar happening in like circumstances. But knowledge thus gained can neither be of full value to the student himself, nor be readily imparted to others unless systematised by means of proper statistical methods.

No one who has followed the discussion that has centred round the question of the efficacy of vaccination can but have been struck by the conflicting results claimed to have been drawn from the same set of figures. With few exceptions, neither side made legitimate use of the statistics. Had they been submitted to a critical analysis, as it is now understood, such divergent conclusions could not have worried our legislature, nor is it likely that so unsatisfactory a law as the recent Vaccination Act would have disfigured the Statute Book of Great Britain. Mere columns of figures, however correct they may be as records of facts, are both useless and dangerous if they are not scientifically analysed.

The object of the present paper is to give a brief and non-mathematical description of the newer statistical methods. No apology appears to be necessary for bringing this subject before medical readers at the present time. The terms and expressions of the subject are daily becoming of more frequent use, and the great importance of this branch of study is being more fully realised. Formulæ are the necessary shorthand of every science. For the purpose of describing the characteristics of any set of tabulated figures it is clear that expressions of some sort are required that will briefly give the greatest possible information. For instance, in dealing with the death-rate from any disease the common method of stating the "average age at death" is often not only insufficient but actually misleading. By the addition of a few simple expressions we can accurately give certain useful and important information about the statistics which enables their distribution to be clearly defined. To explain these terms and to show how they are used is the main object of this paper.

In order to make the subject intelligible to the non-mathematical reader we have kept all mathematical formulæ out of the text, but in places where it seemed that a little more information might be of help to anyone with mathematical interests we have appended notes outlining in brief the principles involved. There has been some difficulty in deciding how much could be excluded without rendering the paper too incomplete, but we hope sufficient has been said to fulfil the unambitious task that we have set ourselves. That the paper is totally inadequate for anyone who intends working practically at the subject we are well aware, and it is not intended for any such; but if it raises interest in this important branch of research in anyone hitherto unacquainted with it, and if it makes intelligible terms that will become more and more frequent in medical and biological literature we shall have attained our object.

To give a more or less connected account of our subject it is first necessary to show how events that are universally recognised as "chance occurrences" fall into definite order if a sufficient number of them are examined; and then it will be seen how statistical data assume corresponding regularity and fall under a similar law of distribution. The second division of the paper, dealing with correlation, has perhaps a more obvious use and will claim the attention of all medical readers. The work initiated by Galton and perfected by Karl Pearson has given us the means of expressing accurately the interdependence of two series of events. By the correct use of their methods we are able to make reliable deductions from the statistical data which experiments and observations afford. Thus the results of vaccination, antityphoid inoculation, &c., can be stated in such a manner as to show clearly what is the true value of these processes.

Theory of Probability.

The object of the theory of Probability is to obtain an accurate measure of the likelihood of the occurrence of events under conditions some of which are known and some unknown. Algebraically the probability of the occurrence of an event is expressed by a fraction, the numerator of which represents the number of ways in which the event can happen and the denominator the sum of the number of ways in which it can happen and in which it can fail. Thus, if a person holds one ticket in a lottery in which there are three prizes and seven blanks the number of ways in which the event—winning a prize—can happen is three and the number of ways in which it can fail is seven. The probability of his winning a prize is therefore 3/10. The probability of not winning a prize is 7/10. In popular language this is generally expressed by saying "the odds against winning a prize are 7 to 3."

The sum of the two probabilities, i.e., the probability of the event happening added to the probability of its failing, is unity. That this must be so is clear from the consideration that the chances of an event either happening or not happening is certainty, for it must from the premisses do either one or the other. The measure of the probability may vary from unity—which denotes absolute certainty of the occurrence—to zero, which means absolute certainty of its non-occurence.

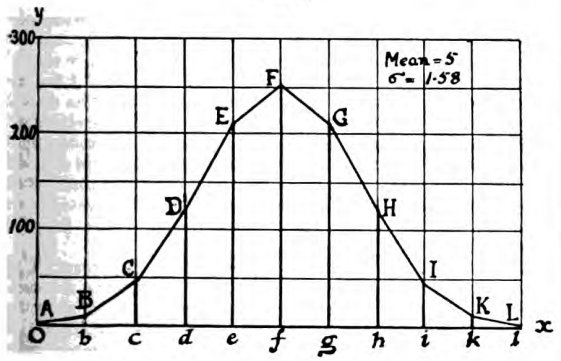
If a coin be tossed the probability of a head turning up is $\frac{1}{2}$, for the event can only happen in one way and fail in one way. Similarly, the probability of a tail is $\frac{1}{2}$. If now two coins be tossed (Example 1) there are four possible results—viz., HH, HT, TH, TT, where the first letter is supposed to belong to one coin and the second to the other. There is therefore one result in which 2 heads may turn up, one in which 2 tails may turn up, and two results in which 1 head and 1 tail may turn up. The respective probabilities are therefore: no heads $\frac{1}{4}$, 1 head and 1 tail $\frac{1}{4} + \frac{1}{4} = \frac{1}{2}$, 2 heads $\frac{1}{4}$. By following this line of argument it can be shown that if three coins be tossed the different possible results and their respective probabilities are as follows:—0 heads 1/8, 1 head 3/8, 2 heads 3/8, 3 heads 1/8. If 10[1] coins be thrown the

[4] Brit. Med. Jour., April 17th, 1909.

[5] This case, which has never been published, was under the care of Mr. Rutherford Morison, who has kindly allowed me to mention it. The man swallowed his teeth in July, 1901, but did not come under Mr. Morison's care until December, when he was wretchedly ill from semi-starvation and showed unmistakeable signs of perforation of the left bronchus. Gastrostomy was performed and later an unsuccessful attempt was made to remove the teeth by the stomach route. In February, 1903, the œsophagus was opened in the posterior mediastinum and the teeth extracted, but death occurred about 48 hours later. The post-mortem examination disclosed a large perforation into the bronchus, with extensive septic broncho-pneumonia and microscopic evidence of an older tuberculosis.

[1] The probabilities are given by the successive terms of the expansion of the binomial $(\frac{1}{2} + \frac{1}{2})^n$ where $n = 2, 3, 10$ in the examples given above.

different possible events and their respective probabilities are:—



No of heads.	Probability.	No. of heads.	Probability.
0	1/1024	6	210/1024
1	10/1024	7	120/1024
2	45/1024	8	45/1024
3	120/1024	9	10/1024
4	210/1024	10	1/1024
5	252/1024		

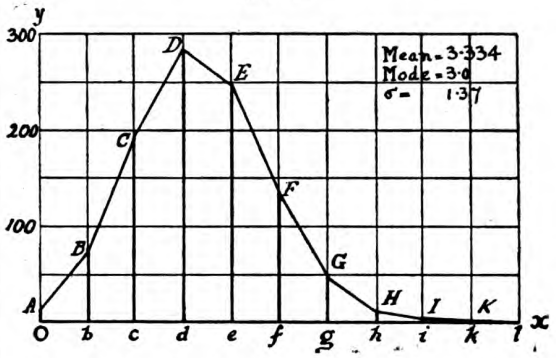
On examining this table (Example 2) it will be seen that the most likely result is 5 heads and 5 tails, but that 4 heads and 6 tails and 4 tails and 6 heads are nearly as likely, while the other possible results are very much less frequent.

Looking at the subject from a somewhat different point of view, the result of throwing a coin a very large number of times will be to give approximately as many heads as tails, or to be quite accurate the difference between the number of heads and the number of tails will be negligible as compared with the total number of throws, when the latter is made sufficiently great. In the same way, if 10 coins be thrown a very large number of times the distribution of the various possible combinations will be approximately proportional to the probabilities given above. If, for example, 10 coins are thrown 1024 times there will be theoretically 1 case in which there are no heads, 10 cases in which there are 1 head and 9 tails, 45 cases in which there are 2 heads, and so on. This particular experiment has been actually carried out and the approximation to the theoretical result was, as we shall see later, very close.

We are now in a position to consider a method of representing graphically such results as these and we begin with example 2. On a piece of squared paper (Fig. 1) take a

FIG. 1.

point 0 and draw through it the horizontal and vertical lines $0x$ $0y$. Let successive points 0, b, c, d, &c., along $0x$ represent the successive cases in which there are respectively 0, 1, 2, &c., heads. Now along $0y$ measure off a distance 0 A = 1 on a convenient scale. Along the vertical through b measure on the same scale a distance 10 and along the vertical c measure a distance 45, and so on. By this means we get a series of points A, B, C, &c., whose distance from $0x$, $0y$ are respectively proportional to the number of heads turned up and the corresponding number of cases in which this occurs. If, now, these points be joined the resulting figure A, B, C, D, &c., is called a frequency polygon for this distribution of events. It is clear from the table of the figures that it is symmetrical about Ff.



In order to show a somewhat different type of polygon another example, Example 3, is here given. The mathematical work by which the result is arrived at is omitted as being

No. of white balls.	Frequency.	No. of white balls.	Frequency.
0	112	7	102
1	725	8	15
2	1938	9	1
3	2819	10	0
4	2467		
5	1353		10,000
6	470		

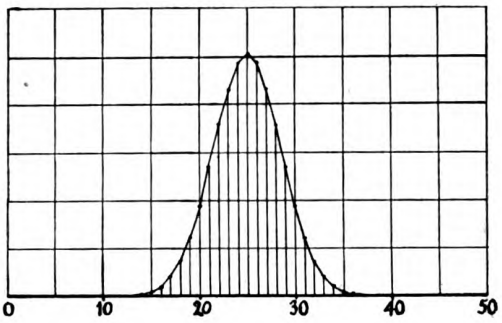
rather complicated for this paper, though the general principles involved are the same as in the previous case. If from a bag containing 40 black and 20 white balls 10 balls be drawn at random these may be (1) all black, (2) 1 white and 9 black, (3) 2 white and 8 black, and so on. The actual numbers which would theoretically be obtained in 10,000 draws are given in the accompanying table.

It will be noted that, as a rule, there will be no draw of 10 white balls in the total of 10,000 draws. Theoretically, 10 white balls will be drawn only once in 400,000 draws, or but once in 40 of these experiments. If these figures be now plotted in the manner explained above the following polygon results (Fig. 2). It will be seen that the polygon differs

FIG. 2.

somewhat from the previous one, in that it is not symmetrical; the greatest ordinate is two spaces distant from the middle of the base and the polygon tails off to the right. In both examples the ordinates increase in size from left to right till they reach a maximum and then decline again till they almost vanish. The maximum ordinate represents the frequency of the particular arrangement which is most likely to occur. Thus, in Example 3 there are more likely to be 3 white and 7 black balls than any other combination. Nevertheless, if a sufficient number of trials is made all the different combinations will occur in perfectly definite proportions and will be distributed according to a definite mathematical law. While it is impossible to foretell what the result of any particular draw will be, we can predict the result of a large number of draws with an accuracy which depends solely on the magnitude of the number.

It is, perhaps, well to point out here that the rare event—as, for instance, the drawing of 10 white balls from the bag—is as essential a part of the mathematical law as is the frequent occurrence of the commoner or more likely events. If, therefore, in a large series of events we were to find that the rare event did not occur sufficiently often we should have just as much right to suspect some unrecognised factor in our experiment as we should if we found it occurring too frequently or if we found that the commonly expected event did not occur sufficiently often. This is a point that is often overlooked, more especially in the case of statistical data, but it is an important one to recollect.



If an experimental result differs by more than a certain small amount[2] from what theory tells us it should do there must be some factor influencing the result which was not included in the known conditions of the problem—e.g., in the case we have been considering some irregularity in the shape of the coins or some difference in the size or weight of the balls.

It may be difficult for the reader to grasp the exact bearing of these examples on the practical problems of statistical work, but, as a matter of fact, it has been shown by much experimental research that a large variety of statistical numbers are of the nature of chance distributions and fall into various types of polygons (and curves) of a kind similar to those given above. It is only by studying the simpler forms that the more complicated types which occur practically can be understood. The polygons of Examples 2 and 3 are both 10-sided. If we threw 50 coins instead of 10 and plotted the resulting distribution we should get a 50-sided figure. This has been done in Fig. 3, and it becomes clear

[2] This amount is known as the "probable error" and will be discussed later.

that when the number of sides is so far increased the polygon approximates very closely to a continuous curve. It would, in fact, be very easy to draw a continuous curve through

FIG. 3.

the angles of this polygon.[3] Such a curve is known as a "frequency curve"; and one of the chief problems in this branch of statistical work is that of fitting such a curve to a given polygon, thus smoothing out the irregularities of the polygon, which, owing to the smallness of the data, will not be regular like the theoretical examples given.

We proceed now to study more closely the nature of these polygons and begin by defining certain terms which have an important bearing on their practical application.

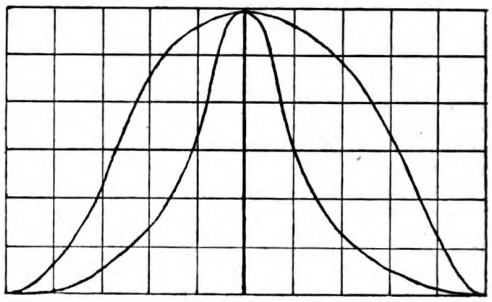
The *mode* of a frequency curve or polygon is the abscissa of its greatest ordinate—i.e., it is the numerical value of the combination or the events which occur more frequently than any other. In Example 2 the mode is 0f = 5, the number of heads which turns up more frequently than any other. In Example 3 it is 0d = 3, or the number of white balls which is drawn more often than any other.

The *mean* of a frequency polygon corresponds to the abscissa of the centre of gravity of the figure; in other words, it is the average of the abscissæ of all cases. Thus in Ex. 2 there is one case whose abscissa is 0, 10 cases whose abscissa is 1, 45 whose abscissa is 2, &c., the mean is therefore

$$\frac{1 \times 0 + 10 \times 1 + 45 \times 2 + \ldots}{1 + 10 + 45 \ldots}$$

This works out at 5, and the mean therefore coincides with the mode as it must do in a symmetrical polygon. In Example 3 the mean is—

$$\frac{112 \times 0 + 725 \times 1 + 1938 \times 2 + \ldots}{10{,}000} = 3{\cdot}334,$$



and it extends, therefore, to the right of the mode. A clearer conception of the mean may perhaps be obtained from a simile given by K. Pearson. Suppose on a light uniform straight rod, A B, weights are hung at equal distances, the weights being proportional to the frequencies of the various events—i.e., proportional to the ordinates of the frequency polygon. The centre of gravity of the rod thus weighted is the position of the mean and is clearly not necessarily coincident with the position of the greatest weight—the mode.

While the terms "mode" and "mean" are strictly defined as abscissæ—i.e., as *lines* measured from the origin along the axis of x—it is sometimes convenient to speak of the *points* where these lines terminate as the position of the mode or mean. Thus in Example 3 it is common to say that the mode is at 3, and the mean is at 3·334.

We require now to find a quantity which will give us a numerical measure of the extent to which a distribution is spread out. If the two polygons in Fig. 4 be compared it is apparent that while their means may coincide, one is much more spread out than the other—that is, its distribution has a greater deviation from the mean. The numerical measure of this spreading out is called the *Standard Deviation*, and is defined as "the square root of the mean of the squares of all the individual deviations." If it be denoted by σ, then σ is found by summing the frequencies of the events multiplied by the squares of their distances from

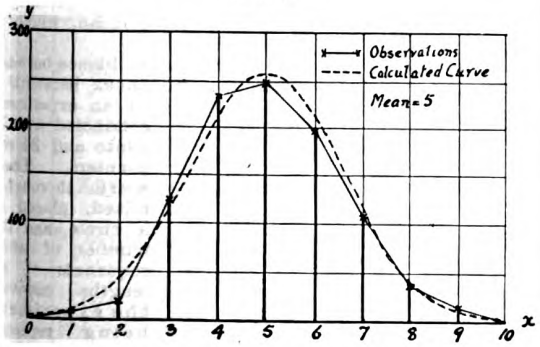
FIG. 4.

the mean, dividing by the total frequency, and extracting the square root. Thus in Example 2, $\sigma = 1{\cdot}58$ and in Example 3, $\sigma^2 = \frac{112 \times (3{\cdot}334)^2 + 725 \times (2{\cdot}334)^2 + \ldots}{112 + 725 + \ldots} = 1{\cdot}88$, $\therefore \sigma = 1{\cdot}37$. An extension of the illustration used above for the mean will probably give a clearer conception of this measure. Let the weighted rod be made to swing about the centre of gravity. The more closely the mass is concentrated about the centre of gravity the less will be its energy and momentum, and the more widely it is distributed the greater will be its energy and momentum. Now a point can be found at which if the whole mass be hung the energy of the swing will be the same as if the mass were distributed along the rod as in the figure. The distance of this point from the centre of gravity is the swing-radius of the system and is found by multiplying each mass by the square of its distance from the centre of gravity, dividing the sum of all these products by the total mass and extracting the square root. The swing-radius of the system corresponds therefore to the standard deviation of the frequency distribution.

The Standard Deviation gives us a measure of the variability of any particular distribution, and is a concrete number, its magnitude being dependent on the magnitude of the classes. If, however, we wish to compare the variability of two different distributions we must reduce their "standard deviations" to a common basis. This is given by the *Coefficient of Variation*, which is the percentage of the standard deviation on the mean; in other words, 100 times the standard deviation divided by the mean. In Example 2, $\sigma = 1{\cdot}58$, coefficient of variation = 31·6 per cent.; in Example 3, $\sigma = 1{\cdot}37$, coefficient of variation = 41·1 per cent. Thus although the magnitude of the standard deviation of the distribution of Example 2 is greater than that of Example 3, yet when they are put in a comparable form the variation relative to the mean or the coefficient of variation is actually less in 2 than in 3.

It has already been pointed out that there is a difference of symmetry between the polygons 2 and 3. The first is symmetrical and the second asymmetrical or skew. The measure of the *skewness* is the difference between the mean and the mode divided by the standard deviation; for it is clear that the farther the mean and the mode are apart the greater is the skewness, and the more the curve is spread out the less the skewness. The skewness is positive when the mean is greater than the mode. Skewness in Example 2 = (5–5)/1·58 = 0; in Example 3 = (3·334–3)/1·37 = 0·024.

Before turning to the examples of statistical distribution it might be as well to explain that there are two different methods of plotting frequency polygons. In the one which we have hitherto employed ordinates are drawn proportional in height to the frequency of the events at successive points along the axis of x. In the second method rectangular areas are drawn whose bases are equal increments along the axis of x, while their heights, and therefore their areas, are proportional to the frequency of the events occurring within



[3] A close approximation to the distribution in the general case $(p+q)^n$ when n is large is given by the curve $y = y_0 e^{-x^2/2\sigma^2}$, where $y_0 = \frac{N}{\sigma\sqrt{2\pi}}$, N being the total frequency and $\sigma = \sqrt{npq}$. This illustrates the change from the discontinuous binomial to the continuous curve.

the limits of the base. Thus in Fig. 7 the number of cases whose age lies between 30 and 35 are represented by the rectangle standing on that base. It follows that the total area of the polygon is proportional to the total number of cases. The first of these methods is more conveniently used for those distributions in which the events occur at fixed intervals, as in the coin-tossing experiments; while the second method is employed for those distributions in which the counts have to be artificially separated into groups, as in the measurements of heights, ages, &c.

It now remains to show that statistical numbers fall into distributions of the same type as these purely chance ones, that they are not chaotic, but follow definite and determinate laws, and that by examining the nature of a particular distribution much more can be learned about it than appears from the ordinary methods of statement.

The simplest form of curve and one into which a considerable number of statistical figures fall is known as the "normal curve of error." If a large number of measurements be taken of any particular quantity, few or none of the measurements will be identical with the true value of the quantity measured—e.g., if a distance of a mile be measured along a straight road the results will differ from the true mile, some by an amount of less than one foot, some by an amount less than two feet and more than one, and so on. If all known sources of error be excluded there will still be a considerable variation from the true value, some of the measurements being less and some greater—i.e., some of the errors in the result being positive and some negative. Mathematicians, on the assumption that there are a large number of sources of error and that these are equally likely to be positive or negative, have shown that the distribution of the final errors gives a particular form of curve. This curve is symmetrical about the mean and extends indefinitely to the right and left, but at a short distance from the mean becomes asymptotic to the axis of x,[4] i.e., practically coincident with it. Although this type of curve was principally studied in connexion with investigations into the statistics of error, it applies to a number of other frequency distributions. As a simple example, let us consider the coin-tossing experiment already referred to. The experimental result of tossing 10 coins 1024 times is given in the annexed table. These numbers have been plotted in Fig. 5, in which

FIG. 5.

the ordinates at 0, 1, 2, &c., are proportional to the number of cases in which 0, 1, 2, &c., heads were turned up. From these numbers has been deduced the equation to a normal

No. of heads.	(1)	(2)	(3)
0	0	2	1
1	8	10	10

	1024	1024	1024

[4] Its equation, taking the ordinate through the mean as the axis of y, is $y = y_0 e^{-x^2/2\sigma^2}$, where y_0 is the greatest ordinate and σ the standard deviation.

curve which has been drawn in the same figure. It will be seen that it gives a close approximation to the polygon, smoothing out the irregularities of the latter. For the sake of comparison the accompanying table contains in column (1) the experimental numbers, in column (2) the numbers given by the curve, and in column (3) the theoretical numbers given by the expansion of the binomial.

We proceed now to give an example of a statistical distribution falling under the same law, and for this purpose the heights of 1052 women are classified in the following table. Here Row (1) gives the height in inches, all cases falling between, say 57 inches and 58 inches, being classified as 57·5 inches. Row (2) gives the number of cases of each given height. For example, out of the total of 1052 women, 18 were of height between 57 inches and 58 inches. Row (3) gives the theoretical numbers given by the "normal curve."

Stature in inches	54·5	55·5	56·5	57·5	58·5	59·5	60·5	61·5	62·5
Observed frequency	1	2	7	18	35	80	136	163	183
Normal frequency	1	3	8	21	45	81	124	160	174

Stature in inches	63·5	64·5	65·5	66·5	67·5	68·5	69·5	70·5
Observed frequency	163	115	79	41	16	8	5	2
Normal frequency	159	123	80	43	20	8	3	1

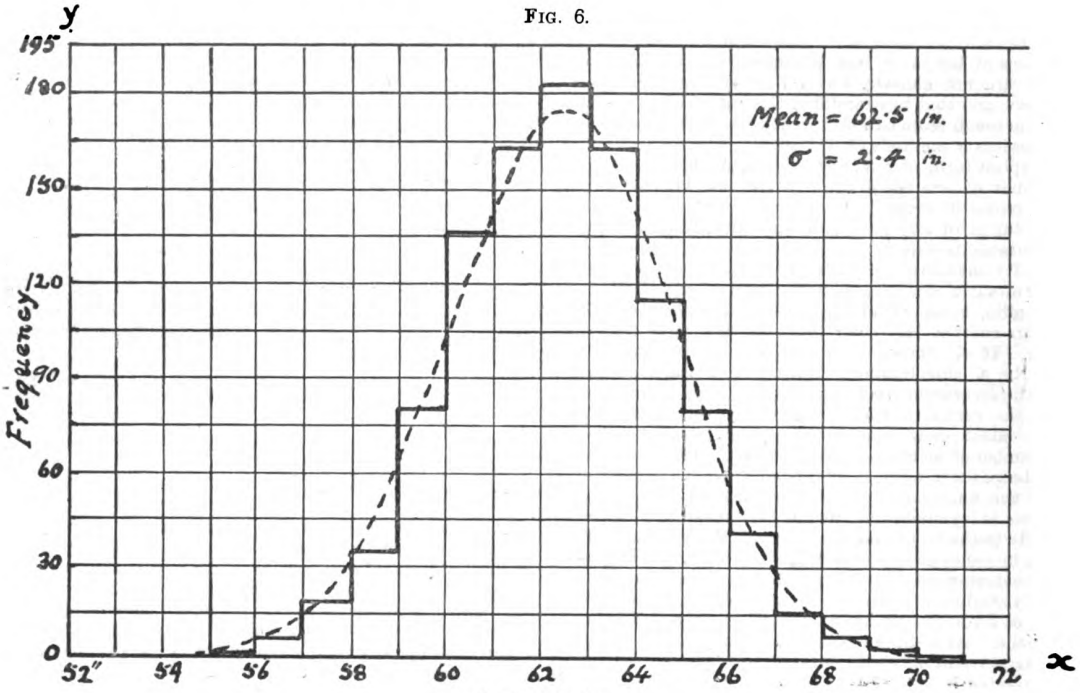
This table has been taken from K. Pearson, "Biometrika," vol. ii., but has been simplified by omitting the decimals as they were unnecessary for the purposes of illustration.

It is easily found that the mean and the mode of the distribution are coincident at 62·5 inches, while the amount of variation from the mean is measured by the standard deviation = 2·4 inches.[5] The whole distribution is graphically shown in Fig. 6, and the normal curve calculated from the numbers is seen to fit very closely to the polygon. It seems clear from these examples that certain distributions can be closely represented by a curve of the type known as the "normal curve of error," and that the statistical distribution given above falls under the same law as that derived from pure chance.

That the normal curve will not fit all distributions is obvious merely from the fact that it is symmetrical, while many statistical series are not so. To Professor K. Pearson is due the credit of having evolved a method of calculating the constants for curves, one form or another of which can be applied to any set of statistical figures which are in any way of the nature of a chance distribution. The mathematical theory of these curves cannot be given here, but the general method of procedure in a given case may be briefly indicated. The system of curves falls into three main types, together with four subsidiary types, which are limiting and therefore simpler forms of the main types. One of the subsidiary types is the "normal curve of error" with which we have already dealt.[6]

From the given set of statistical data a certain constant is calculated whose value shows to which of the seven types the given series most closely approximates. The type being thus discovered, the constants of the curve can then be calculated, and hence the equation to the curve determined. From this a series of ordinates corresponding to the chosen series of abscissæ can be found and the curve plotted in the same units which have already been used for the observations. This having been done, comparison can be instituted between the given statistics and the theoretical distribution which approaches most nearly to the actual numbers. The following table giving the age of spinsters at marriage, taken from the Tasmanian Reports for 1904, may serve as an example of a non-symmetrical distribution. The polygon, which has been plotted in Fig. 7 in the usual manner, will clearly not be

[5] The equation for this curve is $y = 174{\cdot}3\, e^{-x^2/2}\,(5{\cdot}71)$, where $y_0 = 174{\cdot}3$ and $\sigma^2 = 5{\cdot}71$.



[6] The division into three primary and four secondary types is for the convenience of calculation. The same fundamental differential equation $\frac{1}{y}\frac{dy}{dx} = \frac{(x+a)}{b_0 + b_1 x + b_2 x^2}$ applies to all, and the equation which results from integrating this depends upon whether the roots of the quadratic $b_0 + b_1 x + b_2 x^2 = 0$ are real and of like sign, real and of different sign, or imaginary.

fitted by a normal curve, but a very close approximation to the statistics is given by the curve drawn in the figure; it belongs to Pearson's Type V.[7] This has been calculated by the method indicated above. The important constants of the distribution are shown in the figure.

It might be well to notice here, although the point has already been referred to, that much more information is gained by this means than is afforded by the mere statement of the mean. This information is, of course, all embedded in the statistics, but it is more or less hidden away until some such method as this presents it in a form in which it can be grasped almost at a glance. Thus we see that while the mean age of spinsters at marriage is 24·8, the age at which the greatest number of marriages takes place is 22·5; that the number of marriages rises very rapidly from the age of 15, and that after passing 22·5 the number decreases rapidly, but less so than it rose, while it tails off to the age of 50 to 55. The standard deviation is 4·7, indicating that about three-fourths of all marriages take place between the ages of about 19 and 28.

An example of a distribution which differs still more from the "normal" is given in Fig. 8. Out of a large number of soldiers who were sent to India 7000 contracted enteric fever after varying periods of residence. The distribution, according to the length of time that elapsed between arrival and development of this disease, is shown in the diagram. Thus, 2561 cases out of the 7000 occurred within one year of their arrival, 1500 cases in the second year of residence, and so on. The curve in this case starts at a great height about the third month and rapidly descends, tailing off till the eighth year. It will be seen here how very little information as to the distribution of the statistics would be given by a simple statementas to the position of the mean, which is at 2·16 years.[8]

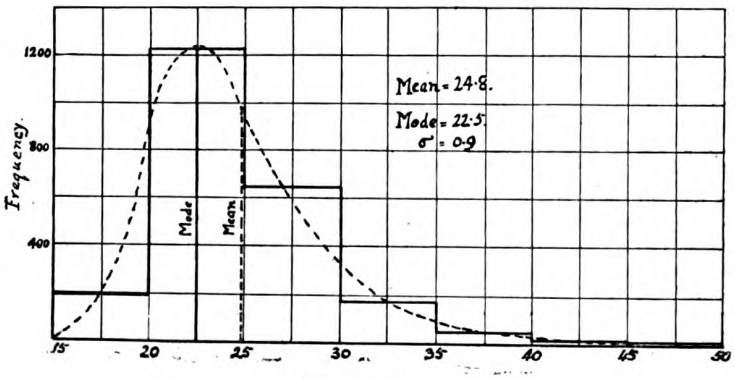


FIG. 6.

Height in inches.

In order to show once more the close resemblance between chance and statistical distributions we annex herewith a table in which are given the results of an experiment conducted with 74 white and 26 red counters. These were thoroughly mixed, placed in a circle, and the number of white sequences of all lengths counted, the experiment being repeated until a total of 1000 sequences was reached. From the numbers thus obtained a curve was calculated by Pearson's method which was found to agree very closely with the theoretical numbers deduced from the theory of chance. The following table gives the numbers (1) by actual experiment; (2) those

FIG. 7.

Age at marriage.

[7] The equation for this curve is $y = y_0 x^{-12·79} e^{-31·147/x}$, where log. $y_0 = 13·5877$.

[8] The equation for his curve is $y = 23·62 \left(\frac{x}{6·479} - 1\right)^{-·4105} \left(1 - \frac{x}{14·54}\right)^{·9211}$

given by the curve; and (3) the theoretical numbers from the theory of probability:—

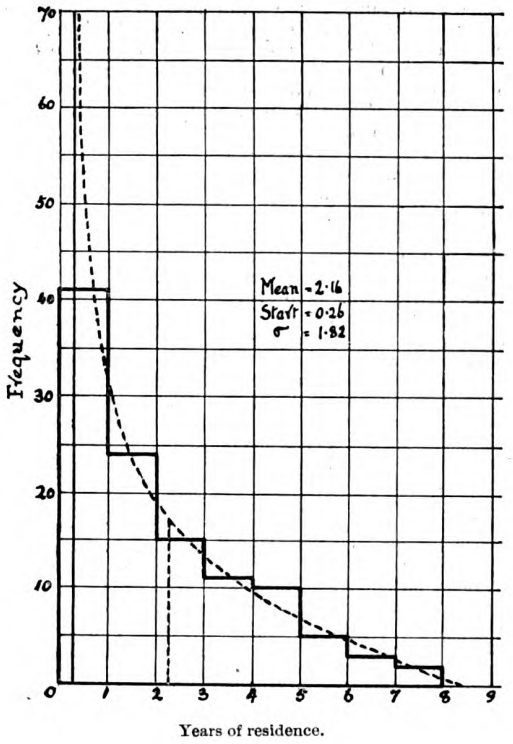
2	1	1

A glance at the numbers will show that they give a curve of the same nature as the last statistical example given above.

In any series of statistical data information is never given with regard to the whole population, or the total number of existing cases. In measuring the heights of individuals in a particular race or class, in classifying the ages at which a certain disease attacks any population, and so on, we are unable under ordinary circumstances to deal with more than a small proportion of the total number of possible cases. We have therefore to be content with a *sample* of the population which we are studying and to make the most of such data. If these figures are to give us reliable results great care must be taken to see that the sample dealt with is strictly a *random* one—that is to say, that it has not in any way been selected in respect to the quality we are about to deal with, nor in respect to any other quality that is associated in any degree with the one that we are concerned to measure. For example, if we wished to obtain a measure of the mean height of Englishmen it would not be right to take the height of hospital patients, for the mean thus obtained would be vitiated by the fact that these people are mostly drawn from the poorer classes and from the towns, and are therefore probably below the average in physical development.

FIG. 8.



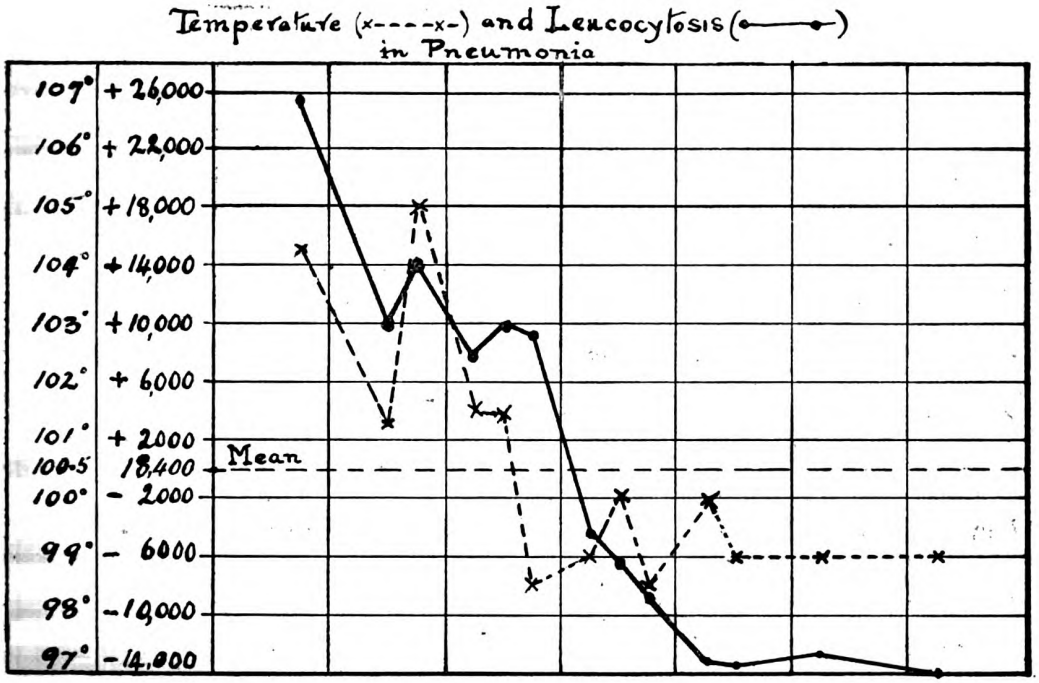


FIG. 9.

Assuming then that we have got a random sample to study, we want now to know how far the results calculated from this group may be taken as fairly representing the general population; in other words, we require a numerical measure of the degree of accuracy with which the constants of the sample would agree with those we should obtain had we been able to deal with the whole population. This measure is given by the *Probable Error* which may be defined as the limit on either side of a given measurement within which

it is an even chance that the true value lies. Take for example, the value of the mean in Fig. 6. Here we are dealing with a random sample of the whole population and the mean height of our sample is not likely to coincide with that which we should obtain were we able to measure the whole. By means of the theory of error, however, we are able to say that it is an even chance that the true value lies within the limits 62·5 ± 1·5 inches—i.e., between 61 and 64 inches. Thus ± 1·5 inches[9] is the probable error of 62·5 inches, the mean of this particular sample. This gives us the measure therefore of the accuracy of our numerical constants. Without such a measure most statistical results are of little scientific value. The chief factors in determining the size of the probable error are the total number of cases dealt with and the standard deviation of the distribution. The smaller the number of cases the larger will be the probable error, while the smaller the standard deviation the smaller will be the probable error. Again, to get a true idea of this measure it must be looked at, not as an abstract number but in relation to the value of the constant to which it is attached. For instance, if the mean height of women was found from the sample to be 62·5 ± 1·5 inches, the probable error in this case might be regarded as small, but if we were considering the length of human feet whose mean was 9·5 ± 1·5 inches, the probable error would here be very great. Although the actual figure which represents the probable error is numerically the same in the two cases, the comparative values are very different.

It must be clearly understood that the probable error is only a measure of the mathematical want of exactitude of the statistics and in no way a criterion of the correctness of the observations. No mathematical treatment can compensate for incorrect data, although possibly the form of the resulting distribution may lead the expert to suspect that the statistics are not correct records.

It has already been stated that the probable error gives the limits within which it is an even chance that the true value lies. Now it does not mean very much to say that it is an even chance that a certain event will occur, but if we know that the odds in favour of the event are 100 to 1, then we have much sounder justification for anticipating that the event will probably happen. Theory shows us that the odds in favour of the true value lying within the limits of twice the probable error are 4·5 to 1, within three times 21 to 1, four times 142 to 1, while the odds in favour of the true value lying within eight times the probable error are 17,000,000 to 1. When such long odds exist it becomes highly likely that the event will fall within rather than without these limits.

Correlation.

Two series of phenomena are said to be correlated when we find certain values of the one phenomenon occur more commonly with given values of the other. Correlation may be positive or negative. If the increase in the values of one series of phenomena is associated with an increase in the other, the correlation is positive, if the increase in the one series is associated with a decrease in the other the value is negative. If we find the same value of the one occurring indiscriminately with any value of the other there is no correlation. Thus in many diseases the pulse-rate rises and falls with rise and fall of temperature—i.e., body temperature and pulse-rate are correlated phenomena. If 100 men be measured as to height and weight it will be found that on the average taller men weigh more—i.e., weight and height in men are correlated characters. The one-foot earth temperature varies with the amount of sunshine and with the amount of rainfall, increasing with the former, decreasing with the latter, but dependent on both. There is positive correlation between one-foot earth temperature and amount of sunshine, negative correlation between one-foot earth temperature and amount of rainfall.

The study of correlation has for its object the determination of a quantitative measure of the degree of association in such phenomena as these. The method of arriving at this measure will be best illustrated by an example. In Osler's "Principles and Practice of Medicine," p. 178 (sixth edition), a chart is given which is designed to show that the leucocytosis which exists in most cases of acute pneumonia disappears coincidently with the decline in temperature. This chart is reproduced in Fig. 9 modified so as to illustrate our present subject—i.e., the curves have been superimposed one on another and the mean temperature made to coincide in position with the mean of the number of leucocytes. Inspection of this figure is sufficient to show that on the whole there is a distinct resemblance between the two curves. We will now proceed to indicate the method by which a quantitative measure of this resemblance is obtained.

If we examine the two curves in detail we notice that their resemblance to one another depends on the circumstance that a deviation above the mean in the one is generally accompanied by a deviation above the mean of about the same amount in the other, and a deviation below the mean in the one by a deviation below the mean of about the same amount in the other. On the other hand, they are dissimilar in so far as a deviation above the mean in the one may be accompanied by a deviation below the mean in the other, or a large deviation in the one by a small deviation in the other. Now the product of two positive quantities, or of two negative quantities, is positive, while the product of a positive quantity by a negative quantity is negative. If, therefore, every deviation from the mean—i.e., every ordinate of the curve (1) be multiplied by the corresponding ordinate of curve (2), each being given its appropriate sign, the result would be a series containing a large number of positive terms and a small number of negative terms. If, on the other hand, the curves were very dissimilar the reverse would be the case—i.e., there would be many negative and few positive terms. The quantity thus obtained gives therefore a foundation for the measure which we require, being large and positive if the curves are similar, large and negative if they are complementary (as though the first curve were reflected in a mirror), and small or zero if there is no resemblance between them.

In order to get a satisfactory measure for the comparison of different cases this quantity is divided by its maximum value, which is the product of the standard deviations of the two distributions, multiplied by the number of observations. The ratio thus obtained is called the *Coefficient of Correlation* and is denoted by r. If the two curves are the same $r = +1$. If the one is the reflection of the other $r = -1$. Between these two limits r may take any value. This will be made clearer if we work out the temperature-leucocytosis example we have been considering. For this purpose the observations are tabulated in columns (1) and (4) of the annexed table. The deviations from the means are given in columns (2) and (5), the squares of these deviations in columns (3) and (6), while their product is given in column (7).

(1)	(2)	(3)	(4)	(5)	(6)	(7)
104·2	+3·7	13·96	44·0	+25·6	655·4	+94·71
101·3	+0·8	·64	28·0	+ 9·6	92·2	+ 7·68
104·8	+4·3	18·49	32·0	+ 13·6	185·0	+58·48
101·6	+1·1	1·12	26·0	+ 7·6	57·8	+ 8·36
101·4	+0·9	·81	27·6	+ 9·2	84·6	+ 8·28
98·6	−1·9	3·61	27·4	+ 9·0	81·0	−17·10
99·0	−1·5	2·25	13·8	− 4·6	21·2	+ 6·90
100·0	−0·5	·25	11·4	− 7·0	49·0	+ 3·50
98·6	−1·9	3·61	9·2	− 9·2	84·6	+17·48
100·0	−0·5	·25	5·2	−13·2	174·2	+ 6·60
99·0	−1·5	3·25	4·8	−13·6	185·0	+20·40
99·0	−1·5	3·25	5·8	−12·6	158·8	+18·90
99·0	−1·5	3·25	4·0	−14·4	207·4	+21·60
	0	54·74		0	2036·2	255·79

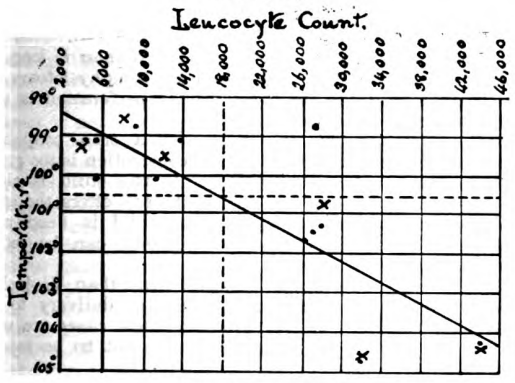
Those who have grasped the definitions of mean and standard deviation given in the first part of this paper will have no difficulty in following the arithmetical work involved in making the necessary calculations. The sum of column (3) divided by 13—the number of the observations—gives the square of the standard deviation of the first distribution, and similarly for column (6). These standard deviations are therefore respectively 2·05 and 12·87, and the value of r is 255·79 divided by 13 × 2·05 × 12·87 = ·76. This shows

[9] The probable error of the mean is equal to $0{\cdot}67449\sigma/N$. This shows the direct relation of the size of the probable error to the standard deviation.

that there is a very considerable correlation between the temperature and leucocytosis in this case of pneumonia.

It is clear that if a system of 100 or more observations had to be tabulated the above method of procedure would be a very lengthy and cumbrous one. It has been very much simplified by adopting another way of arranging the data, which we will illustrate by means of the same example. Through a point near the centre of a piece of squared paper draw two axes at right angles to one another (Fig. 10). Along the horizontal axis mark off

FIG. 10.



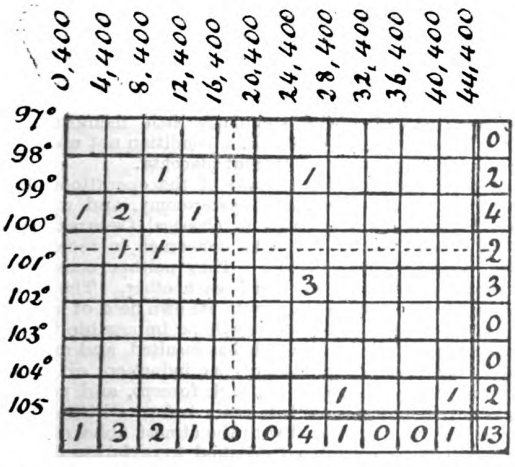


Diagram of regression line

deviations from the mean of the temperature, and along the vertical axis deviations from the mean of the leucocyte count. By this means each observation can be represented on the diagram by a single point whose abscissa is its deviation from the mean temperature and whose ordinate is its deviation from the mean leucocyte count. The observations are then represented by a system of dots most of which lie in the upper left hand and lower right hand quadrants. They occupy a belt running from corner to corner of the paper. If the curves were quite similar to one another, so that the abscissæ and ordinates of the points were in a constant ratio, these dots would actually lie on a straight line. If one curve were the complement of the other the line would run from the lower left hand to the upper right hand quadrant. If there were no association the points would be scattered indiscriminately about the paper. This is

FIG. 11.

a point to which we shall return later. Meantime, we proceed to show how the arithmetical work of finding the coefficient of correlation is now to be carried out. A "correlation table" is constructed on the same principle as the figure, the dots being replaced by numbers, each of which is equal to the number of observations lying within its own compartment. (Fig. 11.) By adding these numbers in rows and columns we get the two distributions of the observations, one according to temperature, the other according to leucocytosis. The denominator of the fraction which has been defined as the coefficient of correlation is 13 times the product of the standard deviations of these two distributions. The numerator of the fraction is found by adding together all the products obtained by multiplying the numbers in the table by their respective ordinates and abscissæ giving them their appropriate sign (ordinates positive above the axis of x, negative below; abscissæ positive to the left of the axis of y, negative to the right). We thus obtain as the result $r = (57-4) / 13 \times 1{\cdot}89 \times 2{\cdot}95 = {\cdot}73$. The difference between this result and the previous one is due to the slight inaccuracy introduced by the second method caused by grouping any temperature lying between, say, 100·5° and 101·5° as being at 101°, and by similar slight modifications of the leucocyte counts. The advantage of this method is better seen when large correlation tables are being calculated as the saving in labour by grouping is very great. The number of observations being large the loss in accuracy is negligible.

Returning now to Fig. 10; here the crosses represent the mean points of the different columns—e.g., the mean temperature for all cases in which the number of leucocytes was between 2000 and 6000 is 99·25° In this case the observations are so few that the observations and mean points in several cases coincide. These mean points have a general tendency to be lower in the figure as we pass from left to right. If a straight line be drawn through the mean point of the whole distribution approximating as nearly as possible to the mean points of the columns, the slope of this line will give a general measure of the rate at which leucocytosis increases with increase in temperature. This line is known as the regression line. It can be directly calculated from "r," the coefficient of correlation, and has, as we have seen, a physical meaning.

So far we have only dealt with data which are quantitatively measureable, but it is possible also to construct a correlation table from which "r" can be calculated when the material dealt with is not quantitively measureable. The mathematics of this subject are somewhat advanced, and we shall therefore content ourselves with showing how such a table is constructed, so that references to the method in medical literature may be followed, even though the method itself is beyond the non-mathematical reader. As examples of medical problems which can be solved by this method, we may mention the correlation between vaccination and the power to resist small-pox when contracted and the protective value of antityphoid inoculation. The following example is taken from a paper by one of us on "The Statistical Study of Antityphoid Inoculation" ("Biometrika," Vol. VI.). The statistics are divided into four groups—viz., (1) inoculated and not attacked; (2) inoculated and attacked; (3) uninoculated and unattacked; (4) uninoculated and attacked. These returns were obtained from seven large Indian stations, and are as follows:—

—	Inoculated.	Uninoculated.	Totals.
Not attacked	2192	7940	10,132
Attacked	15	173	188
Totals	2207	8113	10,320

The value of "r" calculated from this by what is known as the "four-fold table" method is $r = 0{\cdot}2395 \pm 0{\cdot}0188$, showing that in this case there is a small positive correlation between inoculation and freedom from attack.

We have perhaps said enough to show that this method gives us a very valuable means of expressing the degree of association between two distributions which cannot be expressed in a graduated scale. This is clearly a great advance in statistical analysis.

CITY OF LONDON ASYLUM.—The new nurses' home of the City of London Asylum, Dartford, Kent, will be opened by the Lord Mayor of London and the Lady Mayoress on Saturday, May 28th.

MODERN METHODS OF DELIVERY IN CONTRACTED PELVES.[1]

BY E. HASTINGS TWEEDY, F.R.C.P. IREL.,
MASTER OF THE ROTUNDA HOSPITAL, DUBLIN.

THE changes recently introduced into operative obstetrics have become sufficiently well established to enable us now to lay down definite rules for precise treatment in any given case of contracted pelvis. In order to do this an accurate knowledge of the pelvic measurements is necessary. Such knowledge can be obtained by the use of Skutsch's pelvimeter, and in no other way so far as I know. It is certain that a knowledge of the length of the diagonal conjugate by no means gives us an accurate indication of the length of the true conjugate. From a theoretical standpoint there is nothing that can be said in favour of such a method, and to those who have made themselves practically efficient in the use of Skutsch's pelvimeter the hopelessness of trying to deduce any accurate data from an estimation of the diagonal conjugate is only too well known. Like all other arts, pelvimetry has to be learned. The proper use of Skutsch's pelvimeter necessitates considerable practice. In the hands of an expert its records are accurate to within one-sixth of an inch. Practically this is sufficient for the adoption of a correct line of treatment.

Theoretically the finding of the pelvic measurements will furnish us with only half the required data, for the size of the fœtal head will still be unknown, but practically this unknown quantity may be disregarded. It is found that the children born at full term of mothers with contracted pelves are up to or even beyond the average weight. In my last 61 cases of contracted pelvis with a true conjugate of 3¾ inches or under the children averaged 7½ pounds in weight. The size of the children may be accounted for by the fact that the presenting part is unable to sink into the pelvis. Therefore the cervical ganglia are not pressed on and escape the stimulation capable of starting the processes of labour at term; consequently these women do not fall into labour until after full term. Whether this be the true explanation or not, the fact remains that it is unsafe to assume that a full-sized fœtus is not carried by the deformed woman.

There is a generally accepted belief that the relative proportion of head and pelvis can be ascertained by Müller's manœuvre—i.e., pressing the head into the pelvis under deep anæsthesia. As a matter of fact this plan often ends in disappointment, for unless the head lies in flexion the method fails in its purpose. It will also fail if the fœtus lies in the third or fourth positions, and in obese women it becomes a matter of considerable difficulty to carry out the manœuvre. At best it is but an adjunct to treatment based on pelvic measurements. By itself it is far inferior to the latter.

It is convenient to classify pelvic contractions into five degrees, the first four of which are separated from each other by ½ inch measurements in the conjugate diameter, whilst the fifth comprises all pelves with a true conjugate measuring less than 2¼ inches. This classification is based on the assumption that a simple flattened pelvis has been measured. The treatment for generally contracted pelvis of a certain degree is that of a simple flattened pelvis with a true conjugate ½ inch shorter. When the degree of deformity is known treatment becomes simple and certain.

Contractions of the first and even of the second degree are seldom diagnosed with certainty unless complications arise suggesting the advisability of taking the measurements. They may lead to abnormalities of presentation, prolapse of the cord, premature rupture of the membranes, and prolonged first and second stages. In the absence of such complications, and even in spite of some of them, a woman may be expected to deliver herself safely if given ample time for the several processes and provided the child is not abnormally large. In such cases trouble usually arises from meddlesome interference, attempts to deliver when the rim of the os is still felt, or the head not fixed in the brim by its largest diameter. The employment of Walcher's position to assist fixation of the head in the brim, and the application of forceps when the head has properly fixed, are both aids that may hasten successful delivery. It is only in the event of danger to mother or child arising that operations for enlarging the pelvic brim need be considered. Induction of premature labour is never required, nor is prophylactic turning justifiable when employed as a measure to aid delivery.

The question of treatment becomes much more difficult in the third degree of contraction, with a conjugate measuring between 3¼ inches and 2¾ inches. With such measurements normal delivery is neither to be looked for nor expected. If the patient is healthy and in suitable surroundings and is seen just before labour starts or early in the first stage, the classical Cæsarean section offers a satisfactory means of delivery. When performed under favourable circumstances it is almost a perfect operation. If the woman is long in labour, with the membranes ruptured, symphysiotomy or pubiotomy should be preferred, whilst perforation is the obvious resort if the child is dead.

In the fourth degree, a pelvis with a true conjugate between 2¾ inches and 2¼ inches, the contraction is too great for pubiotomy or symphysiotomy. If the child is alive Cæsarean section, intra- or extra-peritoneal, offers the only means for rational delivery. If the child is dead perforation with cephalotripsy and cleidotomy can be relied upon for delivery.

When the true conjugate measures less than 2¼ inches abdominal section is the only method of delivery to be considered. Mutilating operations in these cases are very difficult and highly dangerous, therefore not to be recommended.

I have had an opportunity of repeating Cæsarean section on three of our patients. In all these there was no visible stretching of the abdominal scar; there were no adhesions between the intestines and uterus or between the uterus and abdominal wall. The fine silk (No. 3) which was used exclusively to close both the uterus and abdominal fascia had been completely absorbed, although in one case only 11 months had elapsed since the previous operation. Still more satisfactory is the fact that the uterine scars could not be seen and were felt with difficulty.

In spite of these successes I have only felt justified in performing classical Cæsarean section 13 times during the last six years. Many of my cases were not seen sufficiently early, or else had conditions present which contra-indicated the operation. That this is the experience of others whose skill in the performance of the operation places them beyond criticism is evidenced by the opinions expressed at the recent meeting of the British Medical Association. It was there declared that craniotomy on the living child was justifiable and to be recommended if conditions did not seem favourable to the success of Cæsarean section. Personally I do not subscribe to such an opinion and have never found it necessary to perforate a living child.

I have to record one fatality in these 13 operations; the woman collapsed whilst under anæsthesia, immediately after the removal of a very adherent placenta. The operation was attended with singularly little hæmorrhage and death was attributed to shock, a condition not uncommonly seen in association with adherent placenta.

Much has recently been heard of the operations of symphysiotomy, pubiotomy, and hysterotomy, and many think that these are simply rivals to classical Cæsarean section. Were this so, I should not be concerned in recommending them to your consideration. They neither compete with Cæsarean section, nor even with each other. They are complementary operations, each with its own field of usefulness. Until this is clearly realised it will be impossible to stay the present sacrifice of life which has resulted, and must result, from such obsolete procedures as induction of premature labour, prophylactic turning, high forceps, and perforation. It is only a matter of a few years before all these methods of delivery will be viewed with the utmost abhorrence. Not only will it be considered criminal to perforate the head of a living child, but to permit one to die because of delay in delivery, or from obsolete methods, will rightly be condemned.

Symphysiotomy or pubiotomy is to be highly recommended when danger symptoms to mother or child arise during labour with a pelvis not smaller than 2¾ inches in the true conjugate. With both delivery can be easily accomplished, with both convalescence should be uneventful, simple, and painless, and with both the patient may be expected to sit

[1] A paper read before the Obstetrical and Gynæcological Section of the Royal Society of Medicine, Feb. 14th, 1910.

up in bed on the fourteenth day, in a chair on the fifteenth day, stand and take a few steps on the sixteenth day, and walk freely from the seventeenth day. Union in both should be complete, and subsequent pregnancy, if not made easier, should be certainly not more difficult. In favour of symphysiotomy is the fact that no special instruments are required and hæmorrhage is not severe, whilst pubiotomy gains by reason of its greater simplicity and diminished liability to injury of the bladder. Particularly is this so when the subcutaneous method of Professor Bumm is employed.

My personal experience of these operations is covered by 8 cases—2 symphysiotomies, 5 pubiotomies after the manner described by Professor Döderlein, and 1 subcutaneous pubiotomy. It is of this latter that I particularly want to speak, for in it I feel that we at last possess a plan so simple and so safe in technique that we are justified in recommending it for adoption by the general practitioner as a means of successful delivery in obstructed labour.

The operation.—The patient is placed in the cross-bed position, shaved, and disinfected. The vagina is tightly plugged with pledgets of sterile cotton-wool wrung out in weak lysol solution. This is an important step in the operation. The rugæ of the vaginal wall are smoothed out, making the action of the antiseptic more efficient. But its most useful action is dilatation of the vagina, which permits ready and rapid delivery without fear of extensive tears of the soft parts. This plug remains in place about half an hour, whilst the preparations for the operation are finished and the anæsthetic is given.

The operator, seated between the patient's legs, which are allowed to hang down, removes the plug, douches the vagina, and empties the bladder. The site of puncture should be on the skin outside the labium majus. Without any preliminary incision the needle is plunged down to the under surface of the pubes. A finger in the vagina guides its further progress. The needle is made to hug the back of the pubes until it emerges on the abdomen just above the pubes and ½ inch to ¾ inch to the side of the symphysis. A Gigli saw is hooked on to the needle and pulled through the wound when the needle is withdrawn. The bone is now divided in the usual manner without any laceration of the soft parts. This is surprising, for without experience of the operation one would be inclined to believe that laceration would be severe. The fact is that the soft tissues cling so tightly to the saw that they move with it as the bone is being severed. A finger placed on the front of the pubes gives immediate warning of the severance of the bone. An assistant at either side of the patient prevents the pelvis springing apart too suddenly. Labour may be terminated immediately by forceps or version, or the patient may be allowed to deliver herself naturally, provided the child's life is not in danger.

The hæmorrhage which spouts from the punctures when the saw is removed is easily controlled by digital pressure. After the third stage is completed a compress of gauze is the only dressing required. The binder is applied as usual, and to give greater support a broad canvas belt is placed on the outside of the binder around the trochanters. A navvy's belt answers the purpose admirably.

The patient is turned from side to side in 12 hours and can turn herself on the third day. On this day the bowels should be moved; for this the patient is elevated on to the bed-pan by the binder. This raising causes no pain and the patient is always lifted in this manner when the draw sheet is renewed. When the binder is to be changed it is slipped into the hollow of the back, the patient is raised by the belt, and a new binder laid under her. The belt is then slipped up and taken out, the patient raised by the binder, and the belt replaced outside the binder as before. The wound is completely healed within two or three days, and it is impossible to find the puncture marks after a short time.

In performing Döderlein's pubiotomy there is greater fear of infection as a compound fracture is produced; therefore asepsis should be thorough and complete here, as in all obstetrical operations. The incision over the pubes should be vertical, not horizontal. In this way the ligaments are severed and free access to the bone obtained. The bladder should be separated by pressing a gloved finger through this wound. The needle should be made to hug the bone as closely as possible and to emerge outside the labium majus. In both these operations more than one saw should be provided, as they are liable to break.

The technique of symphysiotomy is too well known to need description. There are only a few points to which I desire to call attention. The incision, not longer than 1 inch, should be made on the abdomen above the pubes down to the symphysis. This incision completely obviates the danger of hæmorrhage or injury to the urethra. The gloved finger is pushed into this wound and behind the pubes, separating the bladder. With the finger in the wound the cartilage is cut from above downwards and within outwards. The finger thus protects the bladder from injury. The sub-pubic ligament is not severed if delivery can be accomplished without it. No drainage is necessary. Subsequent treatment and convalescence are exactly the same as in Döderlein's pubiotomy, and the results are equally good.

Were these the only operations at our disposal the treatment of contracted pelvis would still be imperfect and unsatisfactory. There would be no provision for the treatment of the higher degrees of contraction when the patient is far advanced in labour. For such cases forceps and turning are quite impracticable. Perforation is not permissible if the child is alive. Symphysiotomy and pubiotomy should not be performed if the true conjugate is less than 2¾ inches. When these cases are advanced in labour, with ruptured membranes, with the uterus retracted on the fœtus, with Bandl's ring well up towards the umbilicus, indicating a marked expansion of the lower uterine segment, they are notoriously unsuitable for classical Cæsarean section. It is precisely for these conditions that extra-peritoneal Cæsarean section or hysterotomy is indicated.

At present there is an erroneous view that this operation should not be performed if there is a suspicion of the presence of sepsis. Provided the child is alive, the possibility of sepsis should not prevent the operation, for neither the general peritoneal cavity nor the cellular tissue is exposed to any extent, and no unclosed spaces are left when the operation is finished. The risk of sepsis is not increased. To my mind, the non-exposure of the peritoneal cavity and cellular tissue is the greatest advantage it possesses. Therefore I believe that the true extra-peritoneal operation developed by Sellheim is based on wrong principles, for in it the cellular tissue is extensively exposed.

In the operation I am about to describe the intestines need never be seen. Escaping liquor amnii or blood cannot gain access to the general peritoneal cavity. There is no scar to which intestines might adhere. There is no danger of rupture of the uterus in a subsequent pregnancy. Ample room is provided for easy and rapid delivery, whilst the incision passes through a thin wall of relatively non-vascular tissue. Finally, the more advanced the labour and the more marked the lower uterine segment, the simpler becomes the operation.

The operation.—With the usual aseptic precautions a transverse incision is made from one anterior superior spine to the other, passing about one inch above the pubes. This incision is carried down to, and then through, the sheath of the rectus. The upper edge of the wound in the rectal sheath is separated upwards from the muscles, and the latter are divided with the handle of the knife. The transversalis fascia is then broken through and the peritoneum incised transversely. The bladder is raised, putting the vesico-uterine fold of peritoneum on the stretch. A small opening into this fold permits the passage of a finger between the uterus and bladder. On this finger the peritoneum is divided across the whole width of the vesico-uterine fold. The upper edge of the incised peritoneum is seized and separated upwards from the uterus. Its edge is then stitched to the upper edge of the transverse incision in the parietal peritoneum, to shut off the general peritoneal cavity from the field of operation, and to enclose the intestines in a bag of peritoneum. Interrupted sutures should be used, as a continuous suture causes puckering and contraction of the opening. The sutures should be placed well out to the lateral aspect of the opening, closing the angles. If this is not done communication is not shut off, and fluids may enter the abdominal cavity or the intestines may appear at the angle of the wound. It is not necessary to stitch together the two layers of peritoneum above the bladder.

The exposure of the lower uterine segment thus obtained

permits easy delivery. The lower uterine segment and cervix are opened longitudinally. If the head presents it is extracted with the left blade of the forceps and one hand. If any other portion of the child presents it is extracted manually. The cord is clamped and cut. Time is given to allow partial separation of the placenta. During this pause a hypodermic injection of 1-50th of a grain of ergotinin may be administered. Post-partum hæmorrhage was a complication in my three cases. The placenta and membranes are removed, the uterus douched and then plugged with iodoform gauze, the end of which is pushed through the cervix into the vagina. The uterine incision is closed by interrupted catgut sutures; the free edge of the peritoneum immediately above the bladder is united by interrupted catgut sutures to the upper portion of the peritoneum from which it was originally severed. The sheath of the rectus is closed with continuous No. 3 silk sutures, and the edges of the skin wound are brought together by Michel's clamps or in any manner convenient to the operator.

To sum up, my views on the treatment of contracted pelvis are:—

1. Induction of premature labour is never advisable.
2. Perforation is not permissible unless the child is dead.
3. Turning should never be employed as a treatment for contracted pelvis, but may still be performed for complications of labour, such as prolapse of the cord when associated with contractions of the first and second degree.
4. In the greater degrees of contraction time should not be wasted in an endeavour to obtain natural delivery.
5. On the other hand, in the lesser degrees ample time should be given the woman to enable her to deliver herself if possible. Eight or ten hours may be necessary for the moulding of the head, and interference should not be considered until there are evidences of fœtal or maternal distress. Once fœtal symptoms of distress are manifested there should be no delay in delivery. Walcher's position should not be forgotten as an aid to fixation of the head.
6. High forceps should never be applied until all arrangements are perfected for an operation to enlarge the pelvis. It is, in my opinion, a pity to proceed to the latter expedient until forceps have been tried tentatively. It must be confessed they occasionally accomplish their purpose under the most unexpected circumstances.

Finally, in these, as in all other obstetrical operations, the best results cannot possibly be obtained if rubber gloves are not worn.

Dublin.

THE OCCURRENCE OF ACETONURIA IN CASES OF INFECTIOUS DISEASES.

BY ALFRED HARRIS, M.B., CH.B. VICT., D.P.H. CAMB.,
ASSISTANT MEDICAL OFFICER OF HEALTH, SOUTHAMPTON.

THE acetone bodies are present in the urine in a number of diseases, of which the following are the principal: (1) Fevers; (2) gastro-intestinal diseases; (3) diabetes mellitus; (4) post-anæsthetic poisoning first described by Guthrie under the name of delayed chloroform poisoning; (5) recurrent vomiting of children; (6) toxæmic vomiting of pregnancy; (7) acute yellow atrophy of liver; (8) phosphorus poisoning; and (9) starvation.

The acetone bodies which may be found in the urine are: (1) β-oxybutyric acid, $CH_3—CHOH—CH_2—COOH$; (2) diacetic acid, $CH_3—CO—CH_2—COOH$; and (3) acetone, $CH_3—CO—CH_3$. The first is the primary substance which gives rise to the other two bodies. Butyric acid is one of the lower fatty acids, which, it is supposed, can be formed in the body by the breaking down of the higher fatty acids. The oxybutric acid is formed by the oxidation of the butyric acid.

There is no satisfactory explanation to account for the formation of acetone in the body. It is certainly curious to find, as will be shown in the concluding part of this note, that it occurs much more constantly in diphtheria and scarlet fever than in enteric fever. The usual theory propounded to explain the occurrence of acetonuria in disease is the inability of the body to absorb and make use of carbohydrate food, so that the protein and fats have to be decomposed in order to supply the energy of the body.

There are several tests for acetone, of which the following are the most reliable:—

1. Lieben's test. This depends on the formation of iodoform from acetone in the presence of iodine and caustic potash. The urine is distilled and to the first few cubic centimetres of the distillate are added a solution of iodine and caustic potash. It is important to use an aqueous solution of iodine as an alcoholic one will form iodoform without the presence of acetone. A solution of iodine in potassium iodide is usually employed.
2. A freshly prepared solution of nitro-prusside of sodium is added to a mixture of the urine and caustic potash. In the presence of acetone a reddish-brown colour is produced which turns deep red on adding dilute acetic acid.
3. One gramme of solid caustic potash is added to about 10 cubic centimetres of urine. Before it has all dissolved 10 drops of salicylic aldehyde are added. The mixture is then heated to 70° C. In the presence of acetone a scarlet ring is formed.
4. A few drops of a freshly prepared solution of nitroprusside of sodium are added to 3 cubic centimetres of the urine. On the surface of this is run a strong solution of ammonia, which, being lighter, floats on the surface. If acetone is present a well-marked magenta colour appears at the junction of the liquids and spreads upwards. If the time is taken from the addition of the ammonia until the appearance of the colour, a rough indication of the amount of acetone in the urine can be formed. If the urine of a case of scarlet fever or diphtheria is examined daily this time will be found to increase gradually until the reaction no longer is produced.

From an examination of the urines of cases in the Isolation Hospital, Southampton, acetone was found to be present in most of the cases of scarlet fever and diphtheria admitted; as regards enteric fever it was found only in about a third of the cases. According to recent authorities the acetonuria of fevers is to be attributed to the acidosis accompanying partial or complete deprivation of food. If this explanation is correct it seems strange that in a disease like enteric fever where there is diminished absorption of food (as shown by the condition of the tongue, diarrhœa, and pyrexia) acetonuria should only occasionally be met with, and then only at the beginning of the disease. On the other hand, in diphtheria and scarlet fever acetone is almost invariably present even in mild cases where, as there is little disturbance of digestive functions, a fair amount of carbohydrate food can be given. That pyrexia has little to do with acetonuria is shown by the fact of its occurrence in many cases of diphtheria in which no rise of temperature has been noted.

As a general rule it has been found in the cases of scarlet fever and diphtheria treated at this hospital that the more severe the disease the larger is the amount of acetone in the urine, and the longer is the period during which it remains in the urine. In a mild case of diphtheria the acetone disappears from the urine on about the seventh day of disease; in a severe case it may be present up to the thirteenth day. In the so-called "vomiting" diphtheria cases, which are always fatal, the acetone reaction is not more marked than is usually the case with a severe type of the disease. There is no increase in the amount of acetonuria at the onset of vomiting.

The presence of acetonuria seems to possess some diagnostic value in differentiating between diphtheria and scarlet fever on the one hand and an ordinary sore-throat on the other. It is much more constantly present in the former cases. In adults, even in diphtheria and scarlet fever, it is not present so constantly as in children.

Of 197 consecutive cases of scarlet fever admitted into this hospital 167 were found to have acetonuria, which is equal to a percentage of 84·8. Of 96 cases of diphtheria 87 were found to have acetonuria, which is equal to a percentage of 90·6. Of the adults admitted 8 had acetonuria and 7 had none. There were only two cases of diphtheria in children in which no acetone was found; one of these cases was one of laryngeal diphtheria in which the toxic symptoms of diphtheria are generally absent. Of 21 cases of enteric fever only 7 showed some evidence of acetonuria, which is equal to a percentage of 33·3. In six of these 7 cases the acetonuria was so slight as to be only with difficulty demonstrated. Of the 14 cases that had no acetone in the urine 8 were severe cases

A CASE OF LYMPHATISM.

BY LEONARD P. BURT, M.B., CH.B. EDIN.,
LATE HOUSE PHYSICIAN TO CHELTENHAM GENERAL HOSPITAL;
AND
J. RUPERT COLLINS, M.A., M.D. DUB.,
CLINICAL PATHOLOGIST TO CHELTENHAM GENERAL HOSPITAL; TO THE EYE, EAR, AND THROAT FREE HOSPITAL, CHELTENHAM; AND TO WINCHCOMBE COTTAGE HOSPITAL.

THE patient was a well-nourished boy, aged 15½ years, but he looked younger. His parents were both dead, and no history could be obtained about them. He had two brothers and three sisters all alive and well. The boy here referred to was the third in the family; his previous health had been good, and he was employed as a boy-labourer in a stone quarry. During the 12 months before admission a lump in his neck had been growing larger, and in January the workmen in the quarry complained of his laboured breathing when he exerted himself, on account of which he was sent to the hospital. On Jan. 29th he was admitted to the Cheltenham General Hospital under the care of Mr. J. Howell.

On admission there was great dyspnœa; inspiration was more stridulous than expiration. His breathing was unaffected by his position, but was increased by any exertion. Mr. Norman Pike examined the larynx and found both cords in a condition of abductor paralysis. Both pupils were dilated; the right pupil reacted to light more slowly than the left. No nystagmus was present; the ocular convergence was normal. The patient had no headache or vertigo. The superficial veins of the neck and thorax were distended. The note of the house surgeon, Dr. Rae, records that the percussion note over the thorax was normal, and no adventitious respiratory sounds were heard. The thyroid gland formed a large rounded tumour in the neck, larger on the right side than the left. The pulse varied from 100 to 150 per minute; the first sound of the heart was impure; the second sound was forcible and clear. A faint systolic bruit was heard over the pulmonary area. There was no exophthalmos.

As the dyspnœa was becoming steadily worse, Mr. Howell considered it necessary to remove one of the thyroid lobes on Feb. 1st. The boy was very nervous and apprehensive in regard to the anæsthetic and the operation. Three-quarters of an hour before the operation a local anæsthetic was injected. The solution was made according to the formula: ℞ eucaine, gr. iii.; sodii chloridi, gr. xii.; aq. destill., ʒ iii.ss.; sol. adrenalin chlor. ♏. x. (1 in 1000, Parke, Davis, and Co.). Of this solution 8 cubic centimetres were injected into the skin round the right lobe of the thyroid. At the same time morphia (⅛th grain) was administered subcutaneously. As the boy was frightened and crying before the operation commenced, the operator asked for a general anæsthetic to be given. Chloroform was chosen by Dr. Burt as having proved the best general anæsthetic for thyroidectomy. The boy was weeping and crying out with fear at the induction of anæsthesia and there was considerable laryngeal stridor, but as anæsthesia was established it lessened and ceased when the capsule of the gland was incised. The breathing was now quite easy and regular. The conjunctival reflex was never lost. The pupils were moderately contracted. The colour of the face was good and the pulse was 100 beats to the minute.

After the right lobe of the thyroid had been removed and the operation was nearly completed, the patient partly came to from the anæsthetic. More chloroform was given. Almost immediately the boy became pale, and the pallor was rapidly succeeded by cyanosis. No mucus was present in the throat, nor any other obstruction to respiration. The patient ceased to breathe. Silvester's method of artificial respiration was at once begun, and traction was made on the tongue. The head was lowered, a hot fomentation was applied to the heart, and hypodermic injections of ether and strychnine were given. About five minutes later the cyanosis was replaced by a fresh red colour for a few seconds which again gave place to cyanosis. The heart apparently ceased to beat five to seven minutes after the cessation of respiration.

Some remarks made by Dr. A. S. Currie in the recent discussion on Lymphatism, at the Royal Society of Medicine,[1] seem to us very pertinent to this case. They are as follows:—

> The question of inhibition of respiration arose, as anæsthetists well know, at certain periods during the administration.
> When he was conducting his experiments single-handed, if the animal was partially roused from the anæsthetic and he stopped and rapidly anæsthetised the animal, he almost invariably found that the animal died almost as if it had been shot. He was much puzzled by that until he found a paper in the *Anatomical and Physiological Journal* by Professor Rutherford, in which he said he had noticed a similar inhibition of respiration and that it was entirely due to an irritant effect on the nasal branches of the fifth nerve, for he found that if he destroyed those nasal branches by the cautery, and chloroformed the animal, that inhibition did not take place, and if he tracheotomised the animal there was no inhibition.

It was recognised beforehand that this boy was a bad subject for a respiratory anæsthetic, and for that reason local anæsthesia was used. Whether the injection of morphia and eucaine increased or lessened the danger from the general anæsthetic we do not know. It was hoped that it would have had the latter effect. It seems certain that there is present in these cases of lymphatism a morbid susceptibility to shock, and that a stimulus which in a normal subject would be quite harmless may give rise to a fatal reflex inhibition of the heart.

Necropsy.—A post-mortem examination was made on Feb. 3rd. The body was that of a well-nourished boy. There was no hair on the pubes or upper lip, and the body had the appearance of a boy of 13 years rather than of 15½, which was his actual age. There was a wound in the neck and the right lobe of the thyroid gland had been removed. The thymus gland lying behind the manubrium was much enlarged and weighed 37·44 grammes, or a little over 1¼ of an ounce. Microscopical examination of sections of the gland showed no degenerative changes. The gland presented the usual division into lobules, with a differentiation into a cortical and a medullary portion. The corpuscles of Hassall were present in about the usual number and did not exhibit any degenerative change, the condition being a pure hypertrophy of the normal structure.

The pericardium was normal. The heart felt flabby, was small, and when washed free of blood weighed only 8½ ounces. The right auricle was empty; the auriculo-ventricular valve admitted three fingers easily. The valve cusps looked healthy. The right ventricle was also empty. The pulmonary artery and valves appeared quite normal. The left auricle was empty. The mitral valve admitted two fingers. The mitral cusps appeared quite healthy. The left ventricle was empty. There were well-marked plaques of atheroma in the aorta just above the aortic valves. The aortic cusps were healthy. The openings of the coronary arteries were normal and the coronary arteries themselves showed no abnormality. The walls of the four chambers of the heart were of ordinary thickness.

The heart was opened *in situ* before the lungs were removed. A histological examination showed the muscle fibres to be loosely held together, with considerable areas of areolar connective tissue intervening between the fibres. The transverse striation of the fibres was very distinct. The capillary vessels running between the cells were distended with blood corpuscles. Sections were stained with sudan III. and with osmic acid, but there was no evidence of any fatty degeneration present. Sections of the atheromatous plaques showed considerable hyperplasia of the intima and some round-cell infiltration without any fatty degeneration.

Both lungs were congested but healthy. A few pigmented brown spots were noticeable on the surface of each lung. The bronchial glands were large and firm. The papillæ and lymphoid nodules at the base of the tongue were prominent. Both the right and the left tonsils were large and when cut open showed dilated crypts containing offensive cheesy matter. The pharyngeal tonsil was markedly enlarged. In the larynx and trachea no abnormality was noted. There was no evidence of any compression of the trachea. The stomach contained about half an ounce of mucus and was apparently healthy. The solitary lymphoid glands of the small and large intestine and the patches of Peyer stood up in a most striking way above the rest of the surface of the gut. The mesenteric lymphatic glands were large and firm, not unlike the appearance presented by these glands in abdominal tuberculosis, but the glands in this case were of a delicate pink colour, and none were caseous. The appendix was examined macroscopically and microscopically and was normal. The kidneys weighed 5 ounces and 6 ounces and appeared healthy, as did also the two adrenals. The spleen

[1] Proceedings of the Royal Society of Medicine, vol. iii., No. 5, March, 1910.

was small and weighed 3¼ ounces. Macroscopically and histologically it was normal. The pancreas weighed 2¼ ounces; no abnormality was found macroscopically or by microscopic examination. The liver weighed 2 pounds 8 ounces. Histologically the capillaries were found filled with blood, but there was no evidence of chronic congestion. The brain weighed 2 pounds 11 ounces and appeared normal.

A histological examination was made of the bronchial and the mesenteric lymphatic glands; in no case was there any evidence of tuberculosis. The structure of the glands appeared normal, and the condition was one of simple hypertrophy. Histological examination of the thyroid showed it to be a simple parenchymatous goitre. The pituitary gland was not enlarged and its histology was normal. Only one testicle was present in the scrotum; the other was not found. A histological section of the testicle showed a dense fibrous stroma running between the tubules and surrounding them in a firm sheath. No complete spermatozoa were seen.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

The Small Flap Incision for Glaucoma.—Congenital Word-blindness.—Hypopyon Keratitis treated by Pyocyanase.—Exhibition of Cases.

A MEETING of this society was held on May 5th, Dr. G. A. BERRY, the President, being in the chair.

Mr. H. HERBERT read a paper on the Small Flap Incision for Glaucoma. Two years ago Mr. Herbert performed a small operation upon eight glaucomatous eyes which had been already briefly described as a form of subconjunctival paracentesis. By means of a narrow Graefe knife a small rectangular sclero-corneal flap was cut subconjunctivally, with its base at the limbus. This flap might be forced forward a little under the conjunctiva by the intraocular pressure. And probably it tended to shrink slightly in volume through being deprived of its direct blood-supply for a time. Firm reunion appeared to have been thus prevented. The results up to date were available in six only of the eight cases. One case was a failure owing apparently to adhesion of the iris to the wound. In the remaining cases the tension had been reduced to normal by means of linear filtering cicatrices. In two of the cases, however, the complete reduction of tension had occupied a period of a few months. The leakage of aqueous was at first insufficient. Two of the patients were shown at the meeting. During the last five months Mr. W. G. Laws and Mr. Herbert had been operating by means of a similar flap, but broader and hence placed usually above, owing to the possible need of iridectomy, basal or complete, to prevent adhesion of iris to the wound or prolapse. These incisions had been made mostly by means of keratomes and of bent narrow blunt-ended knives. Flaps also 2 to 3 millimetres wide had been utilised in some cases made with the narrow Graefe knife at the outer side of the cornea. It was too early to say more about the results of Mr. Herbert's 14 recent cases than that they were very encouraging. In two cases adhesion of iris had formed to both limbs of the small section, yet had not interfered appreciably with filtration. Combined iridectomy, peripheral or complete according to the state of the iris, appeared advisable with the broader incision in cases in which the pupil did not contract well to eserine. It had been performed in three cases only in this series, and secondary iridectomy two days later in one case. By this operation an attempt was made merely to secure with certainty and safety the same linear filtering cicatrix which was sometimes the chance result of an ordinary iridectomy operation. The length and peripheral position of the typical iridectomy incision favoured gaping of the wound and thus tended to produce a filtering scar. In Mr. Herbert's experience a filtering or fistulous cicatrix was the rule after a successful iridectomy and in itself was sufficient to account for the success.—Mr. PRIESTLEY SMITH said he had been struck by the success of the operation and the small degree of disfigurement caused. Mr. W. Allport had, under his (Mr. Smith's) control, operated by the method upon 11 eyes without any failure, and he (the speaker) regarded it as a very valuable improvement in the methods of treating chronic glaucoma and congratulated Mr. Herbert upon it.—Mr. E. TREACHER COLLINS had had no experience of the operation, but desired to know the anatomical difference between a filtration scar and a fistulous scar.—Mr. F. R. CROSS agreed that the establishment of a fistulous opening made a permanent result more likely after operation for glaucoma than without such.—Mr. LAWS said he had performed the operation 14 times and gave the results; there had been no failure or harm in any case. Sometimes, owing to progressive loss of vision, one had to try other methods.—Mr. ALLPORT gave the satisfactory account of 20 cases in which he had performed the operation.

Mr. J. HERBERT FISHER read a paper on Congenital Word-blindness (inability to learn to read). After alluding to some of the previously reported cases of the condition Mr. Fisher reported four others which had come under his own observation in one girl and three boys. In one of the male cases there appeared to be very suggestive evidence of a hereditary and family tendency to the defect; in another there had been considerable flattening of the left side of the cranium at birth, and a remnant of this deformity could still be easily recognised. Mr. Fisher thought it probable that as further examples of the defect were collected the cases would be found to arrange themselves into two groups: (1) the hereditary group, in which the visual memory centre for words residing in the left angular gyrus failed in development (probably in this group a considerable proportion of the female cases would be found); and (2) a group due to limited meningeal hæmorrhage over the same gyrus, the result of birth injury. This group would account for the well-recognised great preponderance of congenital word-blindness of the male sex. Obstetricians recognised the greater size of the head in male than in female infants at birth; the more frequent necessity for artificial assistance and the greater risk to mother and to infant in the birth of male than of female children. Mr. Fisher pointed out that larger meningeal hæmorrhages at the time of parturition and resulting in birth palsies were twice as common in male as in female children. He urged the necessity for special and private tuition for children with this defect of congenital word-blindness. He thought the phonic method of learning to read, making use of the glosso-kinæsthetic centre to aid the visual memory centre, less likely to lead to a satisfactory result than endeavours to train a vicarious visual memory centre in the right hemisphere. For such training he advocated the "look and say" method of learning to read; the child should use the "word" as its unit of observation and study, and not the individual letters. The "look and say" system had been practically developed by Miss Mason of 56, Romola-road, Herne Hill, S.E., in her "Delightful Reading Box" system, which Mr. Fisher had used with a most satisfactory result in one of his cases reported to the meeting.—Dr. F. E. BATTEN discussed the paper, pointing out that Bastian long before 1900 described the condition and reported cases. He (the speaker) thought it difficult to explain word-blindness on the hypothesis that there was an actual defect in the angular or marginal gyrus. Bastian's view was that it was really a commissural defect. Such cases could, as a rule, read figures well, and he knew the case of a butcher boy who could remember accurately the various orders given to him on his round and deliver the meat properly to the respective houses. He (Dr. Batten) was very favourably impressed with the method of teaching such children which had been described by Mr. Fisher.—Mr. TREACHER COLLINS said that he had seen many cases of the condition and had been surprised to find how common it was. They were frequently overlooked, and attributed to sheer stupidity, to the great discomfort of the child. Several of the patients he had seen had been atrocious spellers. If the British system of spelling had been phonetic the defect would not be nearly so noticeable. In Germany, the language there being much more phonetic, such cases were said to be far less common. He thought they had sufficient visual memory for words to enable them to recognise words when they saw them, but not sufficient to recognise when a letter in the word was out of place or omitted. Some could learn by ear, but not from books.—Mr. R. W. DOYNE objected to the name "word-blindness," and he thought the condition was more common in boys than in girls. The defect was a question of degree, and was not regarded as pathological.

Those who were word-blind would read their lessons aloud so as to learn them.—Mr. FISHER replied.

Dr. A. BRONNER (Bradford) read notes on six cases of Hypopyon Keratitis treated by local application of pyocyanase. Many cases of ulceration of the cornea, especially in elderly people, were most difficult to cure, and often ended in complete destruction of the cornea. In some recent cases Dr. Bronner had applied 50 per cent. pyocyanase eye-drops every hour. In every case the pain had disappeared in a day or two, and the ulcer had healed up more quickly and with less consequent opacity of the cornea than under the ordinary method of treatment (galvano-cautery, carbolic acid, sub-conjunctival injections). Of course, atropine drops and hot fomentations were also used. Pyocyanase was a brownish fluid prepared from broth cultures of the bacillus pyocyaneus, at the suggestion of Emmerich and Lowe, by the Institute of Bacteriotherapeutics at Dresden.

Mr. N. BISHOP HARMAN showed a case of Paralysis of the External Rectus, the result of an accident.

Major W. T. MOULD, R.A.M.C., showed a case of Primary Choroiditis, which Mr. DOYNE discussed, and exhibited a tree of heredity concerning cases he had investigated. It was really an exudation, and the sight was not lost until very late in life.

Mr. TREACHER COLLINS exhibited a case showing Yellow Patches scattered through the Iris Tissue in the Stroma.

Mr. L. V. CARGILL showed a patient with Acromegaly.

Mr. M. S. MAYOU showed two cases of Heterochromia Iridis associated with paralysis of the cervical sympathetic in early life.

Mr. J. H. TOMLINSON showed, and illustrated by the epidiascope, Recent Amaurosis with Unusual Cupping of the Disc in a youth.

Dr. A. S. WORTON showed a case of Congenital Arterial Loop Projecting into the Vitreous.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A CLINICAL meeting of this society was held on April 29th, Dr. J. B. HELLIER, the President, being in the chair.

Mr. H. LITTLEWOOD showed: 1. A case in which Peridiverticulitis of the Sigmoid with a Fistulous Opening between the Bladder and Sigmoid had been successfully operated on. The patient was a male, aged 50 years, who had passed fæces and flatus per urethram for four years, during which time he had been unable to work; there was also a stone in the bladder. The abdomen was opened in the middle line; there was a large mass in the lower part of the sigmoid, which was attached to the posterior surface of the bladder near the apex. This was separated with difficulty, and the openings into the bladder and sigmoid were found. The vesical opening was enlarged and the stone removed, the fistulous edges were pared, and the opening into the bladder was closed with a continuous catgut suture going through all the coats, with the exception of the mucous membrane. The mass in the sigmoid was then removed and the bowel united by an end-to-end suture of catgut. The abdomen was closed and a drainage-tube was inserted into the lower end of the wound. The patient made a good recovery. The portion of the bowel removed showed no evidence of malignant disease, but was a typical example of chronic peridiverticulitis of the colon. 2. A case in which Early Malignant Disease of the Upper Part of the Common Bile Duct, involving the cystic duct and producing intense jaundice, had been removed. The patient was a man, aged 65 years, who was in perfect health until about seven or eight weeks before the operation; at that time he suddenly became jaundiced; there were no pain and no fever. The jaundice increased in intensity and at the time of the operation (March 15th, 1910) he was of a greenish-yellow colour. The abdomen was opened just to the left of the middle line, and a growth, producing complete stenosis, was found at the upper part of the common bile-duct, involving the cystic duct. The hepatic duct was divided above the growth and the common bile-duct below; the parts between were removed, together with the cystic duct and the gall-bladder. The common bile-duct was ligatured, and the hepatic duct was sutured to an opening in the upper surface of the first part of the duodenum. The abdomen was closed with gauze drainage and recovery ensued.

Dr. A. G. BARRS showed a man, aged 30 years, with Chronic Sprue (Psilosis). He went to India in 1901 and was quite well to June, 1908, when the illness began with attacks of acute abdominal pain, vomiting, and diarrhœa. The pain usually came on in the night. The diarrhœa, from one to six motions a day, was frothy, copious, and variable in consistency, and dark straw colour. The attacks would last from two to three months, with intervals of about a month. He returned home in December, 1908, and then began to have a sore tongue and tender gums, being unable to eat hot food in consequence. Latterly the abdominal pain and vomiting had been less. He was pale and had lost much weight. The tongue was sore and red, and the pharynx was red. The fæces showed the presence of B. coli and B. enteritidis sporogenes.

Mr. A. L. WHITEHEAD showed a boy, aged 17 years, who had suffered from Chronic Otorrhœa all his life. There had been an external mastoid swelling for three weeks and facial palsy for one week. There was no vomiting, headache, or other symptoms of intracranial extension, except marked optic neuritis, more intense on the affected side. Very extensive mastoid disease was found at the operation, with extensive pachymeningitis externa, the dura mater over the cerebellum, lateral sinus, and cerebrum being diseased, and a large extra-dural abscess above. Recovery was uneventful; some optic neuritis was still present.

Mr. R. LAWFORD KNAGGS showed a man, aged 58 years, in whom Dry Gangrene of the Arm began the day after the crisis of lobar pneumonia. The brachial artery could be seen pulsating at the bend of the elbow, but there was no pulse in either radial or ulnar artery. No albuminuria was present. No bruit could be heard.

Dr. T. WARDROP GRIFFITH showed a child, aged 9½ years, suffering from Adherent Pericardium in whom præcordial thoracostomy had been performed with but trifling improvement. 2. A man, aged 35 years, with Mitral Disease. He had had pleurisy and pneumonia eight years ago, and dyspnœa ever since. There was no history of rheumatism or chorea until December, 1909, when slight pains in the joints were felt. Tracings showed the complete (i.e., non-rhythmical) irregularity of the heart, and that there was no wave in the jugular pulse corresponding to the contraction of the right auricle at its usual time. There was no true crescendo bruit. When the heart was acting frequently the diastolic bruit ran up to the following first sound, but when long pauses occurred the bruit ceased and there was a period of silence separating it from the following first sound. Probably the auricle had passed into a condition of fibrillation; some of the tracings seemed to show this.

Mr. G. CONSTABLE HAYES showed a man, aged 35 years, who was suffering from Secondary Syphilis with Condylomata, which caused symptoms of mastoid trouble in a suppurating ear.

Dr. ALEX. SHARP showed a girl, aged 19 years, suffering from Chronic Œdematous Laryngitis. She was seen about four years ago, on account of urgent dyspnœa, which had developed in the course of a few days. All the soft tissues of the larynx and the lingual tonsil were enormously swollen, and almost occluded the larynx. In spite of prolonged and active treatment, the condition was still very pronounced, and there was only a tiny glottic chink seen on elevating the thickened epiglottis. The vocal cords were unaffected, and there was no pain and no cough. There was no evidence of tubercle, and no specific history. The nature of the case was uncertain.

Dr. H. H. GREENWOOD showed a case in which a Large Hydronephrosis had been caused by Impaction of a Calculus in the Ureter. The patient was four months pregnant. Laparotomy was performed on May 2nd, 1909; a flap of peritoneum was raised, the ureter incised longitudinally, and the stone extracted. Urine flowed in very small quantity. The wound was sutured, a flap of peritoneum was brought over and sutured, and the abdominal wound was closed. Recovery was uneventful. On Nov. 22nd the patient was delivered of a healthy full-term child; the hydronephrosis was then no longer palpable.

Dr. W. H. MAXWELL TELLING showed: 1. A female, aged 26 years, suffering from Graves's Disease with Unilateral Exophthalmos. 2. A woman, aged 56 years, with Pernicious

Anæmia due to Oral Sepsis. There had been marked glossitis, pyrexial attacks, and active delirium. Treatment consisted of vigorous disinfection of the mouth, arsenic, and sulpho-carbolate of soda. There had been marked improvement in the anæmia, and the mental condition was then almost normal.

Dr. A. BRONNER showed two cases of Asthma of 10 and 23 years' duration respectively treated successfully by the application of the galvano-cautery to the nasal septum and the lower turbinates.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Demonstration. — Exhibition of Patients. — Gonorrhœal Urethritis.—Tuberose Sclerosis.—Ménière's Disease and Facial Paralysis.

A MEETING of this society was held on May 4th, Dr. BYROM BRAMWELL, the President, being in the chair.

The following gentlemen were elected corresponding members of the society: Sir W. Watson Cheyne, Bart.; Dr. A. McPhedran, Montreal; and Sir Thomas Clifford Allbutt, K.C.B.

Dr. D. CHALMERS WATSON gave a demonstration to show that many of the commercial preparations of lactic acid organisms at present on the market were useless, and, indeed, some were even harmful.

Mr. DAVID WALLACE showed: 1. Fracture of the Right Olecranon Process in a man. The accident happened on April 11th and was the result of direct violence; there was marked displacement of the upper fragment. Believing that he could more quickly and efficiently give the man a useful limb, Mr. Wallace employed sutures, and five days later movements were commenced. Three weeks after operation the osseous union was good and movements were fairly free. 2. A case of Volkmann's Ischæmic Paralysis in a boy undergoing treatment. The affection was only occasionally met with, and this extreme case occurred in a boy aged 14 years. When aged 11 he suffered from a compound fracture of the bones of the left forearm. The injury was treated with splints, and at the end of one month symptoms of the present condition commenced. Eight months after the accident an operation was performed either with the object of shortening the bone or the muscles. On admission the degree of extension of the hand was very small, the wrist remained almost at right angles, and it seemed impossible to cure the condition without operation. Mr. Wallace removed the proximal row of carpal bones, and in this way the hand was brought into a fair degree of extension. The hand and fingers were then treated with splints, and the boy could now shut his hand and extend the fingers to some extent; the operation was performed on April 14th. 3. A woman who suffered from Hæmatogenous Infection of the Left Kidney. This organ was excised, and though at the time the patient had a temperature of 102° F. and was very ill, she had made a good recovery. 4. A boy showing the good results of operation for Undescended Testicle on both sides.

Dr. NORMAN WALKER showed a girl, aged 15 years, to illustrate the beneficial effects of treatment by carbon dioxide snow in xeroderma pigmentosum. The case began as one of freckles, which soon developed into numerous malignant tumours on the face and orbit. The lesions had completely healed up and the girl was now apparently cured. If the patient could be kept alive to the age of 19 the tendency to malignancy in such cases seemed to disappear.

Dr. GEORGE MACKAY showed a young man who while working at a steel punching machine two weeks ago received a fragment into his left eye. The fragment remained in the eye for 48 hours before removal, which was carried out by making an incision and using the magnet. It was a rare occurrence for such a foreign body to lodge in the eyeball without doing much damage, but in this case a perfect cure without complications seemed to have been effected.

Mr. ALEXANDER MILES read a paper on the Treatment of Acute Gonorrhœal Urethritis in the Male by Passive Congestion. He said that those who had treated such cases by urethral injections must have felt dissatisfied with the results. The very multiplicity of the applications recommended and the variety of the means employed indicated that no one method had yielded satisfactory results. He did not doubt but that if the surgeon could himself administer treatment and control the patient's *régime* benefit would result, but the nature of the affection rendered such conditions unattainable. To intrust the patient himself with a syringe was, he thought, worse than useless. During the first few months in which Mr. Miles had charge of the lock wards, his experience in the use of injections was sufficient to make him look about for a better method of treatment. The success of Bier's method of treating acute inflammatory conditions suggested that it might be employed in the treatment of gonorrhœa affecting the anterior urethra. A constricting bandage applied to the root of the penis did not give encouraging results, and so an apparatus consisting of a glass cylinder about 7 inches long and 2 inches in diameter was devised. A conical rubber flange made a tight union with the root of the penis, and air was sucked out from a lateral opening by a suction pump. After the patient had passed urine the apparatus was applied and the air exhausted by three or four strokes of the piston. The penis at once became turgid, swollen, and bluish in colour as in priapism, and a few drops of pus exuded from the urethra. No pain or discomfort should be experienced. In from 10 to 15 minutes air was allowed to enter, and after an interval of five minutes air was again exhausted. This was repeated two or three times and the whole *séance* should last about one hour. The treatment was employed once daily and gave better results than when applied more frequently. The discharge was increased in amount and might be tinged with blood. In mild cases a single daily application for 20 minutes proved quite efficient. While the method was in trial films were taken in each case immediately before, and a short time after, the use of the suction bell, and were compared. The results were remarkably constant; there was a distinct increase in the number of fresh, well-formed polymorph leucocytes in the discharge examined after the bell had been used, and the proportion of intracellular cocci was much greater. In one case previous to the application there were numerous extracellular cocci in the discharge, but after its use the cocci were nearly all intracellular and appeared to be less numerous. It would appear that the greater number of intracellular organisms found after suction depended not on an increased power of the individual cells to ingest cocci, but on the presence of a greater number of leucocytes capable of ingesting them. It was not unlikely that an increase in the opsonic power of the patient's serum resulted from the hyperæmia and that thereby the organisms fell an easy prey to the phagocytes. From an experience of over 300 cases of acute gonorrhœa of the anterior urethra treated by this method, Mr. Miles thought that it might be claimed to be more cleanly than injections and that the patient could more easily carry it out safely and efficiently for himself. The method was available in cases of phimosis where the œdema of the prepuce precluded the use of injections. The method was not applicable to cases of chronic purulent discharge and gleet, causing in them marked increase in the discharge, pain, and scalding. In acute cases this treatment even after a single application lessened greatly the pain and scalding on micturition and abolished these by the second day. In the majority of cases where the patient came early for treatment and persevered with it the purulent discharge ceased in about 14 days, though a slight gleety discharge persisted for about a week longer. In a few cases the discharge disappeared after only three or four applications, while in others it continued for three or four weeks. The greatest advantage, however, lay in the almost complete absence of complications. Only in two cases did epididymitis develop. This infrequency in epididymitis connoted a corresponding rarity in the occurrence of posterior urethritis, and in the cases treated by Mr. Miles the classic symptoms of the latter affection were seldom present and were never severe. No case of acute prostatitis or prostatic abscess, cystitis, or of peri-urethral abscess was met with. In only two or three cases did a mixed infection bubo develop. Gonorrhœal arthritis supervened in two cases, and it was interesting to note that in one of these in 15 separate examinations made of the discharge the great majority of the cocci were extra-cellular, showing that the opsonic power was abnormally low. During the first year no internal treatment was employed. The next year balsams, usually in the form of sandal-wood oil or alkaline mixtures, were given in addition.

The difference in the results was not striking, but the addition of drugs seemed on the whole an advantage.

Dr. J. S. FOWLER and Dr. W. E. CARNEGIE DICKSON communicated a paper on Tuberose Sclerosis. Tuberose sclerosis was a rare developmental disease, interesting pathologically on account of the fact that in many cases tumours of the heart, kidneys, and skin were associated with a peculiar form of cortical sclerosis, and clinically because it gave rise to a fairly definite type of mental defect. The case which formed the subject of this paper was, briefly, as follows. A female infant, aged one year, was admitted to the Sick Children's Hospital suffering from convulsions. Her previous history was good, and she had apparently developed like a normal child up to the beginning of her present illness. On admission she was semiconscious and suffering from clonic spasm of the left side of the face. The limbs were flaccid, the knee-jerks were active, Kernig's sign was absent, and the pupils were equal with left internal strabismus. On lumbar puncture the cerebro-spinal fluid was found to contain about 40 lymphocytes per cubic millimetre. After admission the fits ceased and did not recur, but the child remained unconscious, and died from intercurrent empyema a month later. On post-mortem examination there were typical tuberose sclerosis and a tumour of the heart. In the somewhat extensive scattered literature dealing with tuberose sclerosis most of the papers deal entirely with the pathology of the disease, but records of 25 cases have been found on which clinical details are given, and from these the main features seem to be as follows. A neuropathic heredity is commonly met with; the average ages of the parents are 33 and 27 years, so that the disease does not tend to occur at the extremes of reproductive life. Syphilis is not a causal factor. Epilepsy and mental defect are invariable, and the former is in many cases the earliest symptom that anything is wrong with the patient. The convulsions set in during the first year in 50 per cent. of the cases. The convulsions are not specially characteristic; they usually occur in small series at short intervals; Jacksonian and minor epilepsy may also occur. Patients are always defective, usually imbecile. Most cases have been found in institutions for the feeble-minded. The mental condition usually deteriorates along with the progress of the epilepsy. It is somewhat remarkable that notwithstanding the extensive disease of the cortex other nervous symptoms are rare. The most interesting feature of the condition is the association with the brain lesion of other tumours. Renal tumours were present in 17 out of 26 cases. They are nearly always bilateral, and are described in most instances as "cancerous." Heart tumours are probably nearly as common, but in the series studied only four are mentioned. Cases with heart tumour usually die in infancy and are recorded in the literature as congenital tumour of the heart. The tumours are rhabdomyomata. Tumours of the thyroid, thymus, duodenum, and spleen have been reported. From a clinical point of view adenoma sebaceum, which was present in 13 of the 26 cases, is very important, because it is the most readily detected of the tumours, and most likely to lead to a correct diagnosis. It is an affection of the skin of the face which is not uncommon in institutions for the feeble-minded, and has been recognised by dermatologists as associated in many instances with backwardness. The tumours are masses of sebaceous glands embedded in a more or less vascular matrix—sebaceous nævus. The disease tends to shorten life. Two-thirds of the patients died by the sixteenth year. Death may be due to the disease directly either from kidney tumour or the occurrence of acute epilepsy or to some accidental cause. The diagnosis depends on detecting some of the associated tumours in a case which belongs to the group of epileptic imbecility. Some of the tumours of the kidney have been large enough to be felt or have given rise to characteristic urinary changes. It is only within the last year or two that any attempt has been made to diagnose the disease during life, and the credit for having drawn attention to the clinical aspects of the disease belongs in the first instance to Vogt of Frankfort. The following is a synopsis of the post-mortem and histological examination of the case of the infant recorded above. (Summary: Tuberose sclerosis, rhabdomyoma of the heart; immediate cause of death broncho-pneumonia, empyema, and collapse of lung; general toxic changes in organs; no tumours in skin, kidneys, or remaining organs.) The brain showed numerous hard nodules mostly in the cerebral cortex, the arrangement of the convolutions of which was not appreciably disturbed, nor was the pia-arachnoid adherent over them. These nodules—a dozen or more in each hemisphere and varying from the size of a pea to that of a small walnut—consisted of neuroglial overgrowth, with corresponding diminution of the nerve elements proper—cells and conducting fibres. The surviving nerve-cells were increased in size, and showed all stages of degeneration and disintegration. Numerous smaller nodules projected into the lateral ventricles. In the right auricular appendix of the heart there were two small nodules of rhabdomyoma. The histological appearances found in these correspond to the classical descriptions of this extremely rare tumour—viz., very irregular, highly vacuolated cells, possessing "tumultuously" interlacing striated muscular fibres. No lesions of special importance, other than acute toxic changes, were found in the kidneys, liver, and other organs.—Dr. JOHN THOMSON and Dr. NORMAN WALKER discussed the question of the presence of adenoma sebaceum in this disease.

Dr. ALEXANDER BRUCE and Mr. J. S. FRASER read a paper on a case in which Ménière's Symptoms appeared in an Apoplectiform Manner along with Facial Paralysis. Attention was called to the confusion which existed on the subject of Ménière's disease, and it was suggested that this term should be given up in favour of that quoted above. Ménière's symptoms were: deafness, tinnitus, giddiness, nausea, vomiting, cerebellar ataxia, nystagmus, fainting, a feeling of pressure in the head, cold sweats, and diarrhœa. All these symptoms, however, need not be present. It was pointed out that Ménière's symptoms were merely those of irritation or disease of the membranous labyrinth and eighth nerve, and that they might be present in any pathological condition affecting the labyrinth or acoustic and vestibular nerves; they formed a "disease picture" analogous to those of excess of thyroid secretion—tremor, rapid pulse, and exophthalmos. A classification of conditions affecting the inner ear and auditory nerve was given under the following headings: (1) variations in intralabyrinthine pressure or excessive movements of the labyrinth fluids; (2) electrical stimulation; (3) vascular congestion or anæmia; (4) labyrinthine hæmorrhage (traumatic, caisson disease, in bleeding disease, in the exanthemata); (5) acute inflammations of labyrinth; (6) chronic inflammations of labyrinth; (7) neuritis of auditory nerve; (8) hæmorrhage into auditory nerve (the present case came under this heading); (9) degenerations of the auditory nerve, ganglia, and nerve endings; (10) tumours of the auditory nerve; and (11) neuroses (pseudo-Ménière's disease). In the present case the patient was a man, aged 65 years, with a history of rheumatism but not of syphilis. After a day of exposure to cold he went to bed feeling well but woke up the next morning suffering from pain in the head and limbs, extreme giddiness and tinnitus, deafness in the left ear, and left-sided facial paralysis. He remained in bed for a week, and when he did get up had to hold on to the furniture. When seen at the Royal Infirmary two months later he had complete facial paralysis on the left side but no loss of taste; the middle ears were almost normal, but hearing tests showed inner-ear deafness on both sides, most marked on the left side; there was considerable disturbance of balancing; the arterial walls were thickened, and there were cardiac and chronic pulmonary lesions; there was no evidence of leukæmia. Potassium iodide, rest in bed, and electricity did not cause any improvement. The patient died six weeks later from syncope. The post-mortem examination revealed fatty dilated heart, chronic pulmonary tuberculosis, subacute interstitial nephritis, and milky thickening of the pia-arachnoid. The condition of the facial nucleus has been previously recorded by Dr. A. Bruce and Dr. J. H. Pirie.[1] The method of preparing the inner ear for examination (celloidin method) was described. The inner ear was almost normal; there was no hæmorrhage in the cochlea, vestibule, or canals; there were degenerative changes in Corti's organ in the basal coil of the cochlea. In the internal auditory meatus there was, however, a considerable amount of hæmorrhage between the epineurium and the seventh and eighth nerves; the arteries were markedly thickened and the middle coat hyaline; the hæmorrhage did not extend into the aqueduct of Fallopius nor into the modiolus of the cochlea.

[1] Review of Neurology, 1908, p. 685.

A demonstration was given of photomicrographs, showing the condition of the inner ear and auditory and facial nerves. Dr. Bruce and Mr. Fraser had only been able to find one other record of microscopic examination of the inner ear in a similar condition.[2] All others were in cases of leukæmia.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

The Prevention of Small-pox.

A MEETING of this section was held on April 15th, Professor E. J. MCWEENEY, the President, being in the chair.

Dr. T. P. C. KIRKPATRICK delivered an address dealing with the history of the methods that have been from time to time adopted for the prevention of small-pox. He also mentioned the palliative effect of inoculation which was practised in India and China at an early period and which Lady Mary Wortley Montagu introduced into England from Constantinople in the year 1723. This practice, though it lessened the individual liability to death, rather tended to increase the number of those attacked by the disease, and towards the close of the eighteenth century it was estimated that in England 1 in every 14 persons was attacked by the disease, and of those attacked 1 in 5 died. In the beginning of the last quarter of the eighteenth century an attempt was made by Dr. Haygarth of Chester to deal with the disease on modern preventive lines, but his methods were only very partially adopted. It was at this juncture that Dr. Edward Jenner introduced the practice of vaccination. Statistical tables were shown to illustrate the effect of vaccination on the small-pox death-rate in various countries. The address concluded with an account of the methods used for the prevention of small-pox in Germany, where reliance was placed on effective vaccination and revaccination. In England, however, the same reliance could not be placed on the protection of vaccination owing to the absence of any system of compulsory revaccination.

Sir JOHN MOORE said that in his opinion the failure of the present system of dealing with small-pox was in the lack of revaccination. Taught by the lesson of the pandemic of 1870–71, the Parliament of the German Empire passed a compulsory vaccination law in 1874 in accordance with which every child must be vaccinated before reaching the age of one year, and must be revaccinated before 12 years. In Germany the hospital treatment of small-pox presented no difficulty because there was no fuel to catch fire when a spark alighted. Primary vaccination in infancy conferred an absolute immunity for the time being; but that immunity was transitory, and the necessity arose for revaccination at an age approaching puberty. A terrible craze of anti-vaccination was creeping into Ireland, and in the south-eastern part of Leinster there was a decided rebellion against vaccination.

Dr. THOMAS DONNELLY said that something ought to be done to counteract the wave of antivaccination, and one of the best things would be to educate the people by having lectures such as the one which the meeting had just listened to delivered in various centres throughout the country.

The PRESIDENT said that he agreed with the suggestions as to the education of the people. He was responsible for the bacteriological purity of the lymph which was issued to vaccinators in Ireland, and he could testify that it was produced with the utmost cleanliness and asepticity. Vaccine lymph had a very distinct bacteriological flora, which consisted of organisms found in the skin of the calf. When taken directly from the skin some had a certain pyogenic power, like the staphylococci found in the human skin, but after subjection to the action of glycerine they seemed to lose that power. The method of vaccinating direct from the calf to the arm had been found to give too vigorous a local reaction; the micro-organisms had not been attenuated, and the method was very properly not practised in Ireland. He eulogised the services of Dr. S. M. Copeman in advocating the glycerination of lymph as a means of getting rid of these organisms.

HARVEIAN SOCIETY OF LONDON.—A clinical meeting of this society was held on May 5th at the Paddington Infirmary, Dr. H. J. Macevoy being in the chair.—The following cases were shown by the medical superintendent, Dr. Maurice F. Squire: (1) Aneurysm of the Innominate Artery; (2) Tumour of the Breast; (3) Tuberculous Onychia; (4) Suppurative Onychia and Rheumatism; (5) Hæmophilia; (6) Hemi-anæsthesia in a Man; (7) Sclerodermia and Arterio-sclerosis; (8) Myopathic Atrophy; (9) Muscular Atrophy following Plumbism; (10) a case recovering from Facial Paralysis following Mastoid Operation; and (11) Tuberculous Kidney. A specimen was also shown, being the main arteries from a case operated on some six years previously for supposed Innominate Aneurysm. The right subclavian and common carotid had been tied and the case was regarded as a cure. The specimen showed some degree of enlargement of the calibre of the innominate artery and thickening of its walls, but no trace of a previous aneurysm. The right subclavian was occluded at the site of the ligature, but the right common carotid was patent and presented an aneurysm at the site of the ligature.—The cases and specimens were discussed by Dr. Macevoy, Dr. G. de B. Turtle, Mr. E. Laming Evans, Mr. C. E. A. Huddart, Mr. F. C Dodsworth, and Dr. G. A. H. Barton.—The meeting concluded with a vote of thanks to Dr. Squire.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The spring meeting of the Northern and Midland Division of this association was held at the kind invitation of Mr. C. T. Street at Haydock Lodge, Newton-le-Willows, on April 19th. Mr. Street presided.—Mr. E. P. S. Gane read a paper on Notes on the Treatment of General Paralysis by means of Serum. He pointed out how the treatment by specific serum had been brought prominently forward by Dr. Ford Robertson, whose investigations led him to believe that the disease is caused by a micro-organism allied to the diphtheria bacillus. Mr. Gane now wished to bring forward his experience of cases he had treated with the diphtheria antitoxin. The advantage of the serum was that it was standardised and the strengths were definitely graduated. The number of cases in which he tried the serum were six, all of which were general paralytics. The first four cases were disappointing and the fifth could only have been changed by a miracle. In the sixth case after treatment the grandiose ideas and delusions left and mentally the patient showed improvement. He believed that the temperature reaction, temporary excitement, and alteration or improvement in the mental symptoms were probably due to some absorptive process set up by the serum and not to any specific action. In the cases mentioned the disease was so far advanced, the probable permanent destruction of nerve tissue so considerable, that little more than arrest of the process could be expected from the treatment and a transient change for the better.—The paper elicited an interesting discussion in which a number of the visitors present took part. An interesting point brought out was the question of the diagnostic value of the serum in the early stages of general paralysis.—Dr. A. J. Hall of Sheffield read a paper on Insanity following Carbon Monoxide Poisoning, quoting two cases occurring in the same house and under similar conditions. The first was a woman, aged 33 years, who was found unconscious in the bathroom soon after going for a hot bath. She showed most of the signs of CO poisoning, but there was no smell of gas and the "geyser" was turned off. By next day she had completely recovered. The other case was that of her *fiancé* who had been staying a week-end in the house and went to have a hot bath prior to going away on the Monday morning. On bursting open the door he was found unconscious and the room was full of gas; the geyser was full on but with the light out. There was no doubt as to the cause and the symptoms were typical, but instead of complete recovery the patient was dazed and confused, and had loss of memory and incontinence of urine and fæces. This condition continued practically unchanged up to the day of his death, which took place 17 days after the poisoning. Dr. Hall then discussed the question whether the mental symptoms were entirely due to the poison, or was the case one of suicide, there being some prior mental derangement. The opinion of a professor of jurisprudence was quoted: "Whenever an obscure death occurs in a patient about to be married it is suicide."—Remarks on the paper were made by Mr. G. E. Mould, Dr. Cross (who

described a case he had had under treatment), and others.—Mr. Street then opened a discussion on the question, "Are we doing as much in the form of treatment of mental disorder as we might do?" He said that the two points which prompted him to ask the question were: First, the general idea that nothing was done in the way of treatment in asylums, and, secondly, that the recovery rate did not increase. Though much had been written in the way of treatment of the insane, yet treatment did not appear to have yielded many results; the recovery rate had not increased during the past 30 years. He advocated a higher form of moral treatment than the usual occupation, recreation and amusement, a more intimate knowledge of the mental condition of every patient, and particularly a more frank and open method of dealing with it. He believed in discussing a patient's mental symptoms freely with him, whether they were delusions or suicidal inclinations, and had found this method to yield good results, especially in cases of melancholia and alcoholism.—Several members took part in the discussion afterwards.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Preston on May 6th, Dr. W. K. Walls (Manchester) being in the chair.—Dr. A. J. Wallace (Liverpool) read a note on Vaginal Subtotal Hysterectomy. He stated that when removing the uterus per vaginam for small fibroids or for persistent uterine hæmorrhage the idea had occurred to him that removal of the whole uterus was an error, because it prolonged the operation and increased the trouble from bleeding, whilst removal of the cervix permanently weakened the pelvic floor and led to alterations in the relations of the vagina. He therefore adopted the following plan of removing the corpus uteri only. The utero-vesical pouch was opened and the corpus uteri brought out into the vagina. The posterior vesical peritoneum was then sutured to the posterior peritoneum of the cervix uteri; thereby the corpus was rendered extraperitoneal and the peritoneal cavity was closed. The broad ligaments were next sutured and divided as far down as the os internum, and the uterine arteries were ligatured as they bent externally. The corpus uteri was cut away from the cervix, and the anterior and posterior walls of the cervical stump were sutured together. The sutured ends of the broad ligaments were now sewn to the cervix and the vaginal wound closed, a gauze strip being left in the potential cavity behind it.—Dr. W. Fletcher Shaw (Manchester) read a paper on Some Points in the Prognosis of Eclampsia. He based the following conclusions on the results of 46 cases, treated at St. Mary's Hospital during the years 1906–7–8; there were three specially bad prognostic signs in eclampsia: (1) a small amount (less than 10 grammes per litre) of albumin during the eclamptic stage; (2) a high temperature (over 100° F.); and (3) post-partum onset of symptoms. A very large percentage of cases with one of the first two symptoms ended fatally (61 per cent. of 21 cases and 57 per cent. of 18 cases respectively); with the two symptoms combined the prognosis was the very worst (all 12 cases died); with neither of the symptoms the prognosis was extremely good (all 7 cases recovered). The third symptom warranted a very bad prognosis (only one out of eight recovered).—Dr. H. Briggs (Liverpool) showed a recent water-colour drawing from a case of Kraurosis or Leucoplakia Vulvæ under his care, taken for the purpose of testing the conclusions of Dr. Comyns Berkeley and Dr. Victor Bonney, contained in their paper read before the Royal Society of Medicine on Nov. 11th, 1909, that these are two distinct diseases. Dr. Briggs said that both in the laboratory and at the bedside confusion continued as before; the microscopical characters of the tissue changes in the vulva corresponded to those met with in the tongue in leucoplakia. There was superabundant fibrous tissue and no evidence of cancer. On the perineum and around the anus the skin was involved, but the thighs had escaped. The vestibule was affected. An attempt to separate the two diseases in this instance had failed.—Dr. D. Lloyd Roberts (Manchester) reported a case of Pregnancy complicated by a Perinephritic Abscess. In spite of free drainage through a lumbar incision, and the passage of a satisfactory amount of urine, the patient died six days later. A six months' child was born alive during the night after the operation. Post mortem the kidney showed numerous abscess cavities lined by lymph which contained streptococci.—Dr. W. Blair Bell (Liverpool) recorded two cases of Pelvic Tumours associated with Acute Appendicitis. In the one case the gangrenous appendix and the body of the uterus, which contained multiple fibroids, were removed; in the other bilateral ovarian cysts and the perforated appendix. Both cases ultimately recovered.—The following specimens were shown: The President: Tubes and Ovaries from a case of Recurrent Streptococcal Salpingitis.—Dr. J. E. Gemmell (Liverpool): A Uterus removed for Fibroids Complicating Pregnancy.

Reviews and Notices of Books.

A System of Syphilis. In Six Volumes. Volume III. Oxford Medical Publications. Edited by D'ARCY POWER, M.B. Oxon., F.R.C.S. Eng., and J. KEOGH MURPHY, M.D., M.C. Cantab., F.R.C.S. Eng. With illustrations. London: H. Frowde, and Hodder and Stoughton. 1909. Pp. 279. Price £2 2*s.* net; 6 Vols., £10 10*s.* net to subscribers.

THE first section in the third volume of this system deals with Syphilis of the Viscera and is written by Professor Osler and Dr. Alexander Gibson. As might be expected from the large clinical experience of the authors this section is most excellently written. It is essentially practical and illustrated by a number of interesting cases with full clinical histories. Chapter VI., dealing with syphilitic affections of the liver, is perhaps the best and should prove of much help to the practitioner. The section is illustrated with 23 plates, and of these some of the coloured reproductions of microscopic sections are particularly good.

The article on the Clinical Aspects of General Paralysis is contributed by Dr. Charles Mercier. He points out that while syphilis plays a large part in the production of this disease, and, indeed, the chief part, only about 2 per cent. of those affected with syphilis develop general paralysis, so that some other factor, and that a very powerful one, must come into play. What is this factor; and how can the fact that general paralysis is almost unknown in China and Japan, where syphilis is very common, be explained? Dr. Mercier believes that the factor is overwork on the part of the brain, since this disease affects mainly active, energetic, strenuous, successful, busy men. May we then expect that, as Western civilisation spreads among the Japanese, and as the problem of attaining success in life becomes more and more difficult with increasing competition in commercial and other pursuits, this disease will become more frequent among these people? It is true that at the present time these Oriental races are fatalists and less susceptible therefore to anxiety, worry, and depressing influences than are Western nations, but this is likely to be less and less the case in future years. Dr. Mercier is inclined to believe with Dr. F. W. Mott, that there may be a special variety of the spirochæte of syphilis which leads to the development of general paralysis. In an attempt to explain the periodicity of the crises and the gradual improvement that takes place between one crisis and another he suggests the following explanations. Either the poison is poured into the blood in intermittent gushes corresponding with the time of the crises, or it is supplied continuously but does not produce its critical effect until it reaches a certain saturation point, or until the resistance of the body gives way suddenly after a long and equal struggle.

Dr. Castellani contributes the section on Yaws and states in detail his reasons for believing that this disease is distinct from syphilis and is due to the treponema pertenue. He finds the organism constantly in the primary lesion and in the unbroken papules of the general eruption; and although he has not been able to demonstrate it yet in the blood, its presence there is proved by the fact that monkeys inoculated with the blood develop typical yaws lesions in which the

treponema is abundantly present. Further, if the monkeys are inoculated with material from the lesions of yaws whence the treponema has been removed by filtration they do not develop the disease. That yaws is not syphilis seems to be proved by the following facts: patients suffering from syphilis may contract yaws, and monkeys inoculated against yaws may contract syphilis and *vice versâ*. The photographs given illustrating the various skin lesions of the disease are very interesting.

The Legal Responsibilities of Medical Men with regard to Syphilis are many and of great importance. The late Dr. Stanley B. Atkinson discusses in detail the important matters of clinical negligence whether by omission or commission, and professional secrecy and defamation of character. He quotes with approval the words of Junius, "a medical adviser must be the sole depository of his patients' secrets which shall perish with him." It is to be remembered that while the medical faculty, like the other professions, has formed a code of etiquette binding upon its members, yet there is no legal sanction for this custom, and the confidence claimed by medical men is not recognised as binding by a court of law.

The importance of syphilis to life assurance offices is very great, and the question as to the amount of loading required for the lives of persons presenting signs of this disease, or giving a history of its occurrence in the past, is one which is always exercising the medical officers of life insurance companies. Dr. E. M. Brockbank writes upon this subject, and after considering the effect of syphilis as an etiological factor in the production of a number of diseases, he devotes a chapter to the experience of assurance companies in the mortality of syphilitics. After considering at length the opinions of many of the medical referees of the large companies on this matter, he comes to the following conclusions, which will be accepted by all who have had much experience of these cases. A syphilitic proposer is, *ceteris paribus*, not so good a life as a non-syphilitic proposer. Only those syphilitic proposers who are first-class lives should be eligible at any rate of premium. No syphilitic proposer should be accepted until at least three years have elapsed since the date of infection without any secondary or tertiary symptoms having appeared in the interval. No proposer showing any signs of the disease or acquiring the disease after 40 years of age should be accepted.

The concluding chapter deals with the Serum Diagnosis of Syphilis, and is written by Dr. Haldin Davis. He gives a clear account of the principles on which the method is based and of the various procedures for carrying it out. While it is true that no healthy individual ever gives Wassermann's reaction, yet, unfortunately, it does not occur in every case of syphilis; thus, taking all cases of syphilis together, about 85 per cent. give the reaction. No doubt as a result of further investigations some adequate explanation will be found to account for these exceptions. One of the most interesting features of the serum test is that it disappears under the influence of treatment, and in this property we appear to have a scientific method of determining whether or not the treatment has been sufficient to cure the patient. In the same way, as Dr. Davis points out, the application of this test will enable us to decide with much greater certainty the time at which it is safe for a person who has acquired syphilis to marry.

The third volume of this system, like the one preceding it, contains a good deal of repetition. No doubt this is in part inevitable, but the editors might have exercised more supervision in this direction, and so obtained advantage of diminishing considerably the size of the whole work. The present volume is well up to the standard of the first two, and the whole is a credit both to the authors and to the editors, although the latter have not used their powers of control to a due extent.

Quain's Elements of Anatomy: Descriptive Anatomy of the Peripheral Nerves and of the Organs of Special Sense. By E. A. SCHÄFER, Professor of Physiology and Histology in the University of Edinburgh; and J. SYMINGTON, Professor of Anatomy in the Queen's University of Belfast. Part 2, Vol. III., Neurology. With 321 figures, many in colours; one plate (coloured). London: Longmans, Green, and Co. 1909. Pp. 384. Price 15*s.* net.

IN THE LANCET of Dec. 5th, 1908, pp. 1674–75, we gave an account of Part 1 of Vol. III., dealing with the central nervous system, and we have now before us Part 2 of the same volume "containing the descriptive anatomy of the peripheral nerves and of the organs of special sense." The three parts which have been issued complete two of the four volumes which will constitute the whole work, and it is now possible to estimate roughly the leading features of the new edition of the standard British work on the anatomy of the human body. The editors had a most difficult task before them in revising this volume; neurology has been revolutionised and its basal literature largely rewritten since the last edition appeared 15 years ago. While freely commending many of the alterations and improvements which mark this edition, and especially the part now under review, there are certain omissions which, in our opinion, will gravely endanger "Quain's" premier place among the world's text-books on anatomy. The chief of these is the almost complete omission of references to literature and to authorities. We do not say that contemporary research is not sufficiently reflected in the text of the new edition, but we do say that the inquiring medical student and practitioner will receive a very scanty degree of assistance from the British standard work if he wishes to carry out research in anatomy. The door to research is, as it were, shut in his face, and he has to resort to German and French works to discover the present state of knowledge in any particular subject of inquiry.

The section dealing with the distribution of peripheral nerves was so completely and efficiently revised by Professor G. D. Thane in the last edition that Professor Symington's task was rendered comparatively easy in the present. Recent observations by Cushing, Bolk, and Frohse have been added, mostly in small text, but Bardeen's work receives much less attention than it deserves. Head's well-known figures are retained to illustrate the segmental distribution of nerves, but no diagrammatic representation has been given of the numerous experimental and clinical observations which have been made in recent years and which in some respects give a more accurate conception of nerve distribution than Head's classical researches and illustrations. We think, too, that Professor Symington, in introducing Fig. 112—a transverse section of the orbit, eyeball, muscles, and fascia—to replace a figure from Gerlach, has substituted an inferior illustration for one which was excellent. A similar criticism may be made regarding an illustration (Fig. 298) of the lateral wall of the nasal cavity. The former illustration (one by Professor Schäfer) was, in our opinion, more accurate and clear than the one which has replaced it. On the other hand, praise must be given to the new figures which illustrate the middle ear and its relations. Professor Schäfer has introduced many new and excellent figures to illustrate recent advances in our knowledge of the minute structure of the eye and ear.

If in some respects the present edition falls somewhat short of the high ideal expected in the leading standard work of its kind, we are not blind to its great merits and also to the most difficult problem which at present faces both

its publishers and editors. They have to meet the competition of the great standard works now published or being published in Germany and France, and at the same time keep "Quain" within the limits required by the majority of medical men and students. The editors appear to have adopted a middle course, but in our opinion no middle course is possible. "Quain" must be what it has been, and in many respects still is, the leading work of its kind, if it is to continue to receive the universal support of anatomists and of their pupils.

Das Lymphgefässsystem. Von Dr. PAUL BARTELS, Privatdozent der Anatomie und Anthropologie an der Universität Berlin. With 77 illustrations (mostly in colour). Jena: Gustav Fischer. 1910. Pp. 280. Price 12 marks.

THE energy with which the anatomists of all countries have recently applied themselves to a re-investigation of the lymphatic system of the human body arose from a minor alteration of technique made in 1896 by Dr. D. Gerota, now professor of anatomy in Bucharest. Gerota discovered that Prussian blue suspended in turpentine and ether made a most serviceable "mass" for the injection of lymph vessels. That apparently trifling innovation has given us, in the course of 14 years, a more complete, detailed, and practical picture of the lymph system of the human body than was formerly at the disposal of medical men. The picture drawn by Dr. Bartels is clear, accurate, and complete; he has produced a work which will serve anatomists and surgeons throughout the world as a standard of reference for many years to come. To the published accounts of a past and present generation Dr. Bartels has added a personal experience derived from ten years of active investigation.

The first chapter, the result of much patient research, gives a historical summary of our knowledge of the lymphatic system. The history is one of brief periods of activity followed by long periods of rest. The discoveries which led to our present conception of the lymphatic system were, according to the author of this work: (1) the discovery of Asellius of Pavia in the earlier part of the seventeenth century that lacteals were vessels, not nerves; (2) Harvey's discovery of the circulation at the same period; (3) Rubeck's discovery (1650) that the lacteal system ended in the veins; (4) the clear proofs given by William Hunter, Cruickshank, and Hewson (1750–1770) that the lacteal and lymphatic vessels were parts of the same system and that the lymphatic system permeated the whole body; (5) the introduction of quicksilver as an "injection mass" by Nuck towards the end of the seventeenth century and the marvellous (and apparently final) results which Mascagni obtained by this means in the earlier part of the nineteenth century; and (6) the introduction of the Gerota method in 1896.

A full description of the various methods used for injecting and examining the lymph system is given in Chapter II. Future advance seems to lie in obtaining practical methods of "auto-injection" by which lymph vessels may be naturally injected by the vital activity of the organs in which these vessels begin. The evolution of the lymph system is traced in Chapter III.; it appears first in the lowest class of vertebrates—the fishes. In Chapters IV. and V. the development of the lymph system in the embryo and its finer structure in the adult are described. The remaining chapters are devoted to a description of the lymphatics of special parts and organs of the body.

It is plain that a work which contains references to 844 published papers and monographs cannot be summarised in a short notice. In spite of its apparently elaborate nature the practical surgeon will readily find in Dr. Bartels's work such details of the lymphatic system as he may stand in need of. Indeed, the author has kept the surgeon's point of view steadily before him. Although this work is issued as the seventeenth part of Bardeleben's elaborate "Text-book of Anatomy," it may be obtained separately at a price which seems quite reasonable.

The Optic Nerve and the Accessory Sinuses of the Nose. By Professor A. ÓNODI, University of Budapest. Authorised translation by J. LÜCKHOFF, M.D. Edin. With 50 illustrations. London: Baillière, Tindall, and Cox. 1910. Pp. 101. Price 10*s.* 6*d.*

ENGLISH rhinologists have now at their disposal an improved edition of Professor Ónodi's well-known treatise on the anatomical and clinical relationship of the optic nerve to the air sinuses of the nose. The author has availed himself of the opportunity provided by the issue of an English edition to add 23 illustrations and many recent observations which have been made since the original work appeared in 1906. Indeed, the illustrations constitute a feature of the work; they represent clearly and truthfully that complicated part of the base of the skull in which the optic nerve is situated. So minutely has Professor Ónodi studied the variable degrees of development and of relationship of the sphenoidal and ethmoidal cells to the canal for the optic nerve that it is difficult to draw a clear picture of what may be regarded as the normal or more common form. So variable is the relative development of the air sinuses which border on the optic canal that he finds it necessary to distinguish 38 varieties, which are assigned to 12 groups or types.

This work is rightly described as "A Contrit ution to the Study of Canalicular Neuritis and Atrophy of the Optic Nerve of Nasal Origin." The first part of the book (68 pages) is devoted to the anatomy of the sinuses; the second part (33 pages) contains a summary of the numerous observations on the routes by which infective processes may and do spread from the air sinuses to neighbouring nerve structures, especially to the optic nerve. In this connexion the author lays especial stress on the venous routes and on the importance of studying the connexion between the veins of the air sinuses and those of the orbit and optic nerve. It is unnecessary to add that Professor Ónodi's work is a most reliable and important contribution to rhinology.

Remedial Gymnastics for Heart Affections used at Bad-Nauheim. Being a translation of "Die Gymnastik der Herzleidenden" by Dr. JULIUS HOFMANN and Dr. LUDWIG POHLMAN, Berlin und Bad-Nauheim. By JOHN GEORGE GARSON, M.D. Edin., Physician to the Sanatoria and Bad-Nauheim, Eversley, Hants. With 51 full-page illustrations and diagrams. London: Swan Sonnenschein and Co. 1909. Pp. 128. Price 5*s.* net.

THE use of muscular exercises as a means of treatment in certain cases of cardiac disease is now well established, and is very extensively employed, especially in Germany, more particularly at Bad-Nauheim. While the general character of these exercises, especially of the so-called resistance exercises, is known to most medical practitioners, it is probable that many would find it difficult to supply a carefully graduated series of exercises to a patient, since the descriptions given in text-books of medicine are frequently meagre. A want of this kind the book before us is admirably calculated to supply. The exercises are described clearly and without unnecessary verbiage. Each exercise is illustrated by one or more clear photographic reproductions. The advantage of these exercises is that no apparatus is required, with one exception—an exercise for strengthening the abdominal muscles for which a simple mechanical contrivance is used. This exercise, which consists in trunk-bending, is, moreover, one

which would only be used by a patient who could do all the other exercises without much exertion.

The general principles of treatment by baths and exercises are briefly but lucidly set forth, and clear rules are given in regard to the indications for and against their use. The importance of medical supervision is urged, in order to ensure that the exercises are graduated to the patient's capacity. The methods employed for controlling and observing the effects of exercises upon the patient are also discussed, including the observation of variations in the rate, rhythm, and quality of the pulse, the investigation of the blood pressure, and the study of the size of the heart both by percussion and by means of the ortho-diagraph. A further method which the authors describe is to study the effect by testing if fatigue is produced by means of Sommer's analysis. For this purpose an ingenious apparatus is employed whereby any trembling movements in a limb are graphically registered after being split up into their component phases.

The authors are not intemperate in their claims for the value of exercises, and they are careful to give the necessary warnings in regard to the need for care, gentleness, and skilled supervision. The translator has rendered the text into readable English, and the book should prove useful to medical practitioners recommending exercises and Nauheim baths to their patients.

LIBRARY TABLE.

Nervousness. By A. T. SCHOFIELD, M.D. Brux., M.R.C.S. Eng. 1910. Pp. 88. Price 1*s.* net. *Nature's Help to Happiness.* By JOHN WARREN ACHORN, M.D. Pp. 55. Price 1*s* net. (Rider's Mind and Body Handbooks.) London: William Rider and Sons, Limited.—These are two of the flood of little and big books which are being outpoured to-day dealing with what may shortly be called "worry." Worry, of course, is no new foe to humanity, but possibly it is more insistent and incisive in these latter days than it was to our ancestors. For to-day the world is much smaller than it was, and not only do our own troubles worry us but those of the world in general, for the news of any event, whether of real importance or no, is common property within a few hours after it has happened. In old days, to escape from the turmoil and wickedness of the civilised world, men retired into the desert, meaning an uninhabited region where they could obtain the means of livelihood in response to some amount of labour. But to-day such a place hardly exists, and most of us are ground in the mill of having to earn our daily bread in the whirl of a great city with all the additional machinery of politics, both Imperial and local. We cannot get away from them—education, housing, the problems of drink and poverty affect us whether we will or no. Small wonder, then, that our nervous systems are working at high pressure and that sometimes the machine breaks down. The two books before us enter into these matters and to a certain extent show how worry may be met. Dr. Schofield gives a short account of neurasthenia and neuromimesis, and points out the value of suggestion, not hypnotism necessarily, but kindly, thoughtful advice given by the medical man and carried out by the patient. Naturally food, exercise, habits of life, and other adventitious aids are not neglected. Dr. Achorn, who from internal evidence appears to be an American, gives the subtitle to his book of "Ground Treatment." His cure for worry is to go out into the country, to work there, and to sleep on the ground. No doubt this is good advice, but the difficulty for most sufferers, in this country at any rate, is to find the ways and means for putting it in practice. Still, we are glad to see from these books, and many others like them, that nervousness and worry are beginning to be recognised as real diseases, even though not exhibiting a definite causal agent, and it is also well that the fact should be recognised that a patient can do a great deal for himself when in such a condition, if his actions, both mental and bodily, are controlled by a medical man who has studied "functional" nervous troubles.

La Nuova Scienza Medica, ossia La Sifilide Ereditaria ed Acquisita in Rapporto alle Malattie del Corpo Umano. Studi ed Osservazioni ad Uso dei Medici Practi Per il PASQUALE FUSCO. Vol. I. Tipografia: "La Speranza." 1909. Pp. 456.—It is difficult to explain in a few words the contents of this work, but we may say that it consists practically of an energetic attack on most accepted medical opinion. Dr. Fusco starts with the idea that syphilis is the main, if not the only, cause of almost all the diseases of the human body. In some cases the action of syphilis is direct, in others it acts indirectly, producing conditions which Fournier has called "parasyphilitic." He agrees that, on the whole, the syphilitic infection is hereditary, though the acquired disease has a similar effect. He claims that spontaneous cow-pox and the "grease" of horses are the results of syphilitic inoculation from the hands of those who have to deal with these animals. He further urges that all the germs which have been described as existing in diverse diseases are merely the effect, and in no wise the cause, of the maladies with which they are connected. We have not space to follow the author through all the subjects dealt with in this book, but we may mention that he claims to find the support for his theories in the cure of many cases of early phthisis by means of antisyphilitic remedies, especially with mercury, for he holds strongly that tuberculosis is nothing more than the last stage of syphilis. This is merely the first volume of the work, and we cannot but feel that the author is terribly in earnest in all that he writes; he feels acutely the lack of attention which his ideas receive at the hands of his colleagues, and he urges that attention should be paid to the vast importance of syphilis as the real starting-point of many diseases. An attack on cherished beliefs may always do good by causing us to examine more carefully the grounds for the faith that is in us. Again, the wide spread of syphilis does produce a very harmful effect on the race. But we cannot support Dr. Fusco's views.

The Diagnostics of Internal Medicine. By GLENTWORTH REEVE BUTLER, M.D., Sc.D., LL.D., Physician-in-Chief, Methodist Episcopal Hospital; Attending Physician to the Brooklyn Hospital. Third revised edition. London and New York: D. Appleton and Co. 1909. Pp. 1193. Price 15*s.*—This book has been written from the point of view of practical clinical work. It is divided into two parts. The first deals with evidences of disease and comprises (1) a brief consideration of the clinical anatomy and physiology of certain organs and systems—namely, the points which are practical and of everyday utility; (2) a description of the approved and recognised methods of examination; (3) a careful consideration of the many signs and symptoms encountered in the practice of "internal medicine"; and (4) a statement of the diagnostic significance of each sign and symptom—that is to say, the diseases are given, the presence of which is more or less strongly suggested by the finding of a given sign or symptom. The second part is concerned with diagnosis, direct and differential. It contains (1) succinct descriptions of recognised diseases and their symptoms, with (2) special reference to differential diagnosis of each disease. The methods of examining the various organs are plainly and fully described, and the work should prove a valuable guide to the student engaged in the wards or out-patient departments. It would specially help him to acquire habits of thoroughness and method in his clinical work, which might

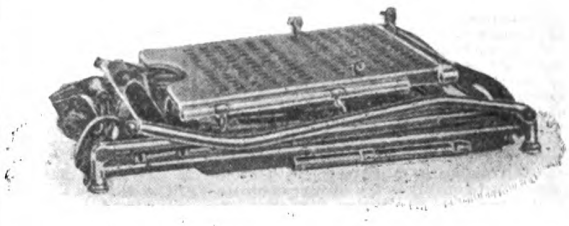
aid him throughout the whole of his professional career. Each section has been made as complete as possible. For instance, in the section describing the examination of the lungs and pleura the topographical anatomy is first explained. Then follows a brief consideration of the physiology of the lungs. Inspection and palpation of the chest with reference to the lungs are then discussed, followed by remarks on percussion, the methods employed, the normal sounds, and the changes produced by disease of the lungs or pleura or of neighbouring organs. Auscultation and the voice sounds are described on similar lines. By considering each system of the body in this way a comprehensive grasp of physical examination and the deductions to be made therefrom can be obtained. The present edition, the third, has been brought thoroughly up to date. The value of the book is increased by five coloured plates and 272 illustrations and charts in the text.

JOURNALS AND MAGAZINES.

The Quarterly Journal of Medicine. Edited by WILLIAM OSLER, J. ROSE BRADFORD, A. E. GARROD, R. HUTCHISON, H. D. ROLLESTON, and W. HALE WHITE. Vol. III., No. 11. April, 1910. Oxford: At the Clarendon Press. Subscription price, 25*s.* per annum; single number, 8*s.* 6*d.* net each.—The contents of this number are: 1. The Question of the Side Affected in Hemiplegia and in Arterial Lesions of the Brain, by Ernest Jones. As a result of a study of the side affected in 5281 cases of cerebral hæmorrhage, thrombosis, and embolism and of hysterical hemiplegia, in 3539 of which the nature of the lesion was determined by post-mortem examination, no evidence was found that with any of these conditions either the lesion or the hemiplegia was more liable to affect one side rather than the other. Any diagnostic significance attributed to the side affected in these conditions is therefore unwarranted. 2. On Acute Pyelitis due to Bacillus Coli as it Occurs in Infancy, by John Thomson, with Pathological Reports on two cases of Pyelonephritis by Stuart McDonald. The clinical features of infections of the urinary tract as seen in infants under the age of two years are described on the basis of a study of 25 cases. In the treatment of these cases two main indications are described—viz., to ensure a copious discharge of urine and to render the urine alkaline and to keep it so for a time. This is done by means of citrate of potassium. 3. So-called Bigeminy of the Heart, by Thomas Lewis. 4. Complete Heart Block and Auricular Fibrillation, by Thomas Lewis and E. Garvin Mack. Both of these papers are concerned with the investigation of conditions of abnormal cardiac rhythm, and are accompanied by tracings and galvanometer records. 5. On the Presence of Hæmagglutinins, Hæmopsonins, and Hæmolysins in the Blood obtained from Infectious and Non-infectious Diseases in Man, by Leonard S. Dudgeon and H. A. F. Wilson. This note forms an abstract of three papers communicated to the Royal Society detailing the results of allowing normal and immune human serum to act in the presence of normal and immune blood cells. 6. Some Remarks on the Work of Andrew Connal, "A Study of Cerebrospinal Fluid in Meningitis," by R. v. Jaksch of Prague. This is a note upon a paper published in a former number of the *Quarterly Journal of Medicine*. 7. A Ventricular Venous Pulse of Regular Rhythm, by E. E. Laslett. 8. On Chylous and Pseudochylous Ascites, by R. L. Mackenzie Wallis and H. A. Schölberg. An exhaustive analysis was made of the pseudochylous fluid removed by paracentesis from a case of chronic nephritis. The authors conclude that the milky appearance was due to a lecithin-globulin complex held in suspension by the inorganic salts present, and that it was not attributable to free lecithin, fat, or to a mucinoid substance. 9. The Myopathies or Muscular Dystrophies, a Critical Review, by F. E. Batten. A classification of these peculiar conditions is outlined and the relationship of myatonia congenita to them is discussed. It is regarded, both on clinical and pathological grounds, as a true myopathy. The pathology of these conditions is reviewed and it is suggested that although for clinical purposes it is convenient to recognise types, they must be regarded as a whole, since there are no hard-and-fast lines between the different types.

New Inventions.

A NEW OPERATING TABLE.



Mr. A. Roubinowitch has submitted for our inspection a new operating table called "L'Unique," combining in a single table the requirements of surgical operations and medical examinations. This table is built entirely of metal and is nickel-plated throughout; it consists of a supporting framework of three pieces jointed at the ends so as to allow of being folded for transport; two moveable arms pass from the frame connected by crossbars imparting the necessary stability. The upper surface of the table is made by three plates and these can be folded on to one another. A head-rest is provided which can be moved in any direction desired by the operator. There are not any delicate or intricate parts to

FIG. 1.

get out of order and the arrangement of the table upon fixed pivots renders the working quite easy and simple. The table is perfectly rigid when set up for use (Fig. 1) and is a thoroughly practical production, having the further advantage that all parts are made interchangeable, so that any one

FIG. 2.

part missing or broken can be replaced without difficulty or delay. The weight of the whole apparatus is only about 60 pounds and it folds up into such a small compass (Fig. 2) that its transport is a matter of great facility. We think that this table may be of great use to many of our readers. The address of the agent in London is Mr. F. A. Mori, 272, Salisbury House, London Wall, E.C.

ROYAL NAVY MEDICAL SERVICE.

A NEW set of regulations for the entry of candidates for commissions in the Medical Department of the Royal Navy have been issued by the Admiralty. The text of the regulations is as follows:—

REGULATIONS FOR THE ENTRY OF CANDIDATES FOR COMMISSIONS IN THE MEDICAL DEPARTMENT OF THE ROYAL NAVY.

ADMIRALTY, January, 1910.

1. Every candidate for admission into the Medical Department of the Royal Navy must be not under 21 nor over 28 years of age on the day of the commencement of the competitive examination. He must produce an extract from the register of the date of his birth; or, in default, a declaration made before a magistrate, from one of his parents or other near relative, stating the date of birth.

2. He must declare—1. His age and date and place of birth 2. That he is of pure European descent[1] and the son either of natural-born British subjects, or of parents naturalised in the United Kingdom. 3. That he labours under no mental or constitutional disease or weakness, nor any other imperfection or disability which may interfere with the most efficient discharge of the duties of a medical officer in any climate. 4. That he is ready to engage for general service at home or abroad, as required. 5. Whether he holds, or has held, any commission or appointment in the public services. 6. That he is registered under the Medical Act, giving the date of his registration as a medical student, or of his beginning professional study. 7. Whether he has previously been examined for entry in the Naval Service and, if so, when.

3. The certificates of registration and birth must accompany the declaration, which is to be filled up and returned as soon as possible, to permit of reference to the candidate's medical school.

4. The dean or other responsible authority of such school will be requested by the Medical Director-General to render a confidential report as to the candidate's character, conduct, professional ability and fitness to hold a commission in the Royal Navy.

5. The candidate will then be interviewed by the Medical Director-General, and his physical fitness will be determined by a Board of Naval Medical Officers. The Medical Director-General will then decide whether he may be allowed to compete.

6. If accepted, he will be eligible to present himself at the entrance examination which will be held twice a year.

7. Candidates will be examined by the examining board in the following subjects:—

(*a*) Medicine, including medical pathology and therapeutics.
(*b*) Surgery, including surgical pathology and clinical surgery.

The examination will be partly written and partly practical, marks being allotted under the following scheme:—

Medicine.		*Surgery.*	
Paper	400	Paper	400
Clinical	400	Clinical	400
Oral	400	Oral	400
Total	1200	Total	1200

8. The appointments announced for competition will be filled from the list of qualified candidates arranged in order of merit; but should it at any time be considered expedient to grant commissions beyond those periodically competed for, the Admiralty have power to admit annually not more than six candidates, according to requirements, specially recommended by the governing bodies of such colonial universities as may be selected and whose qualifications are recognised by the General Medical Council.

Candidates so proposed are to be approved by the Director-General of the Medical Department of the Navy.

They will have to pass a physical examination before a board of naval medical officers in the colony, and will be required to register their qualifications on arrival in England. They will be allowed, if they wish it, to compete at the next examination for entrance and take their position according to the order of merit; should they decide not to compete, they will be placed at the bottom of the list.

A fee of £1 will have to be paid by each candidate to entitle him to take part in the competition.

9. Candidates who have served in the Officers' Training Corps, and who are in possession of the certificates laid down in the regulations of that corps, will be credited at the entrance examination with additional marks as follows: Candidates in possession of Certificate A will receive 1 per cent. and those who possess Certificate A and B 2 per cent. of the maximum number of marks allotted.

A candidate will not be allowed to compete at more than two examinations.

10. A candidate successful at the entrance examination will be appointed as Acting Surgeon in the Royal Navy and will be required to pass through such courses of instruction as the Admiralty may decide. At the end of the courses the Acting Surgeon will be examined and, after he has passed, will be given a commission as Surgeon in the Royal Navy. The commission will date from the day of passing the entrance examination. The number of marks gained at this examination, together with those gained at the entrance examination, will decide a candidate's place on the list for seniority. An Acting Surgeon who fails to qualify in the above examination will be allowed a second trial at the next examination, the period between the two examinations not being counted as service for either promotion, withdrawal with gratuity, or retirement after 20 years' service, and should he qualify, he will be placed at the bottom of his list; should he again fail, his appointment will not be confirmed, and he will be required to withdraw.

11. A gold medal, a silver medal, and three Navy Regulation pocket cases will be awarded as prizes in connexion with these examinations; and the gold medallist will have a distinguishing mark after his name in the Navy List.

[1] If any doubt should arise on this question the burden of clear proof that he is qualified will rest upon the candidate himself.

12. Surgeons on entry are required to provide themselves with a regulation pocket case of instruments.

13. Every medical officer will be required to undergo a post-graduate course of three months' duration at a metropolitan hospital once in every eight years (should the exigencies of the Service permit), and this as far as possible, during his surgeon's, staff surgeon's, or fleet surgeon's period of service. While carrying out this course the medical officer will be borne on ship's books for full pay and will reside at the Royal Naval College, Greenwich. The repayment of travelling expenses to and from his home or port will be governed by the King's Regulations; the fees for each course (not exceeding £25) will be paid by the Admiralty on the production of vouchers at the end of the course. The medical officer will be required to produce separate certificates of efficient attendance in the following:—

I. The medical and surgical practice of the hospital, including instruction in anæsthetics;
II. A course of operative surgery on the dead body;
III. A course of bacteriology;
IV. A course of ophthalmic surgery, particular attention being paid to the diagnosis of errors of refraction;
V. A practical course of skiagraphy.

14. Extracts from the Regulations with regard to pay, promotion, and retirement of medical officers are given in the appendix.[2]

15. The special attention of candidates is directed to the following rules under which officers are allowed to withdraw from the Service after four years' full pay service in the Royal Navy, with the advantage of joining the Reserve of Naval Medical Officers:—After four years' service in the Royal Navy an officer, if he wishes, may pass from Active Service to the Reserve of Naval Medical Officers, when he will reap the following advantages:—(i.) He will be granted a gratuity of £500 on passing into the Reserve. (ii.) His name will be retained in the Navy List; he will retain his Naval rank and be entitled to wear his Naval uniform under the Regulations applying to officers on the Retired and Reserved Lists of His Majesty's Navy. (iii.) If he agree to remain in the Reserve for four years, he will receive a retaining fee of £25 per annum. If, at the expiration of this period, he agree to remain in the Reserve for a further period of four years, he will continue to receive the same retaining fee.

Should an officer prefer it, however, he may simply enter the Reserve for a period not exceeding eight years, with power to give six months' notice of his intention to resign his position at any time (in which case he will receive no retaining fee). He may also adopt this method of Reserve Service after the expiration of four years served under the conditions referred to in (iii.), by renouncing his retaining fee for his last four years' service in the Reserve.

No officer will be allowed to remain in the Reserve for a longer period than eight years.

Officers of the Reserve will be liable to serve in the Royal Navy in time of war or emergency. When called up for such service they will receive the rate of pay, viz., 17*s.* a day and allowances, to which they would have been entitled after four years' service on the Active List.

By Command of their Lordships,
C. J. THOMAS.

These regulations, it will be noted, show certain points of difference from the former regulations which appeared in the last Students' Number of THE LANCET (August 28th, 1909). Confidential reports as to the character of a candidate are now to be obtained from the dean of his medical school. Voluntary subjects in the entrance examination are done away with, and the examination is to deal with medicine and surgery only. In each subject there is to be a written, a clinical, and an oral examination, and 400 marks are given for every one of the six examinations. The subject of hygiene is apparently omitted altogether. Certain additional marks are given to candidates who possess certificates from the Officers' Training Corps. Nominated candidates, except those nominated by colonial universities, are no longer allowed.

The most important alteration, however, is that successful candidates in the entrance examination are no longer given commissions as Surgeons, but only as Acting Surgeons. They have to go through a course or courses at Haslar, and at the end of the courses have to pass an examination for Surgeon. The result of the new regulations will probably be that men will be kept more up to the mark than formerly, and that greater attention will be paid to the courses on tropical diseases and naval hygiene.

Clause 13, which refers to post-graduate courses for officers on service, lays down that during the course the officer shall reside at the Royal Naval College, Greenwich, while the course is taken at a metropolitan hospital. Formerly the officer was granted lodging money and could apparently live where he liked. Under the new regulation a married officer will have to keep up, unnecessarily so far as duty is concerned, two establishments—a room at Greenwich as well as lodgings outside. He will probably, too, have to join the mess, and altogether will possibly be £2 a week worse off than at present, £25 on the three months, which will make it very difficult for some officers to take the course at all. This is a fresh evidence of the little power at the Admiralty wielded by the Medical Director-General, for whom executive authority is much to be desired, that he may protect the interests of medical officers whom he has some difficulty in obtaining.

[2] The exigencies of space prevent us from publishing this appendix.

THE LANCET.

LONDON: SATURDAY, MAY 14, 1910.

The Death of the King.

IT is still hard to believe that KING EDWARD VII. is dead. The blow has fallen upon his country and upon its vast dependencies with such suddenness that it has been, and is, difficult to realise its full import. The newspapers almost to the day of his death had recorded the incidents usual to his busy life. He had visited the Royal Academy a week only before the fact of his illness was first known to the public, and since been seen at the opera and the theatre, apparently maintaining the improvement in his health which was obvious on his return from abroad. He went down to his country home and on return from it transacted a large amount of State business, and received in audience many important persons. He now lies dead in the Palace where he was born not quite 69 years ago, having fallen a victim to a sequence of events all too common under our rigorous skies and among men of his age when duty compels them to lead over-full and over-arduous lives. There has passed from us a great King.

The full measure of his greatness future generations will judge more accurately than we are able to do, but all are realising that the Sovereign whom they have lost was more than a ruler popular with his subjects on account of a genial bearing and a tactful grace exhibited in public, or on account of an able and regular discharge of the conventional functions of royalty. A year after his succession to the throne, as none of us need be reminded, KING EDWARD underwent an operation on the day preceding that fixed for his Coronation. The news of this occurrence came with sensational suddenness, arresting preparations for universal rejoicing which were almost completed, and the whole nation was conscious that it might be called upon to endure the tragic loss of its Sovereign at the very moment fixed for his formal elevation to the throne of his ancestors. Bitterly we should have mourned that loss, but we should never have known its extent, for the finer qualities of statesmanship evinced by KING EDWARD have been shown since his succession to the Crown, when the opportunity to display his capacities was furnished. As PRINCE OF WALES he was conspicuous for his untiring industry in the performance of the duties which QUEEN VICTORIA was able to delegate to him; and he was deservedly popular as a man of wide sympathies and as a prince who entered keenly into the enjoyment of those sports which are dear to the majority of his subjects, and his friends were many. As a King he soon made it apparent that while at home he could occupy the place of a constitutional monarch with kingly dignity, he could exercise an influence in the world at large worthy of his position as the sovereign ruler of a great empire. In a country jealous of its constitution and of the authority of its Parliament, and in which the Government of one year may become the Opposition of the next, KING EDWARD was able so to keep his actions free from the suspicion of party bias that he won and retained the unshaken loyalty and respect of the three estates of the realm and of every section of his subjects throughout his vast dominions. In the dealings of his kingdom with other countries he was able to take a part for which he was singularly fitted by nature and by training. Both had combined to endow him with the knowledge of affairs, the tact, and the advantages of manner and bearing which form the equipment of the ideal diplomatist. He was a King whose influence was not only recognised in the royal circles of Europe, but was felt throughout the nations among which it was his ambition to preserve peace. Of the sincerity of his desire to avert the horrors of war there was never any doubt, nor of the sagacity with which he selected and employed the right means for doing so. The general recognition of what he achieved in this direction has been a conspicuous feature in the popular demonstrations of loyal regret at his decease. In a time of political unrest attendant upon a serious constitutional crisis KING EDWARD has passed away, and there has been heard only the voice of universal sorrow at the death of a loved ruler, combined with tributes of unqualified admiration to the memory of a wise and prudent King. In the midst of party rivalry and contention distinguished by an acrimony unusual during recent years in these islands there has been unanimity in this, and we may quote as illustrating the feeling of all the words of a well-known leader of the Labour Party who, in a speech made while the KING lay dying, said of him: "I feel and I know from the bottom of my heart that he is the greatest statesman the world possesses at this moment."[1]

To the profession of medicine KING EDWARD was a staunch and helpful friend. Twice during his life he had come very near to death, once as PRINCE OF WALES and again on the very eve of his Coronation. On the one occasion, and on the other, so far as such skill could avail, medical and surgical skill saved his life, but to our thinking the view which attributes KING EDWARD'S enlightened interest in medicine to

[1] Mr. Will Crooks at the Browning Settlement, Walworth-road, May 6th.

a sense of personal gratitude is too limited. He was notably a man of warm sympathies whose actions were ever prompted by the desire to aid the people in a practical manner, and in accordance with experience of their needs. In a brief biographical sketch we have enumerated many occasions on which he publicly showed his appreciation of medicine and his certainty that in its scientific practice lay the solution of many of the social problems of the day. As the outcome of such views King Edward's Hospital Fund will remain an enduring monument of his kindliness of heart, of his practical and business-like capacity to promote the success of that which he initiated, and of his insight into the hard facts of the lives of his humblest subjects. He was desirous to provide for those, beyond whose reach they must otherwise remain, the benefits of medical and surgical aid and of nursing, applied in circumstances favourable to success exactly as their wealthier neighbours could command them. Moreover, King Edward's Hospital Fund is a recent institution for the general assistance of the hospitals of the metropolis. Of the full extent of the late monarch's help to individual hospitals throughout the kingdom those connected with them are best aware. Throughout his career as PRINCE OF WALES, as well as during the comparatively few years of his reign, he was ever ready to lend that help which his position and influence rendered of such inestimable value, and the constant association with him in his good work of his Royal Consort, and his son, now our King, will not be forgotten. Beyond this he was conspicuously eager to acquire a comprehensive knowledge of all that was being achieved by science in the way of fresh discovery, to appreciate its utility, to promote its application, and to honour those to whose efforts it was due. The men of science in his kingdom were no mere names to him; he honoured them with his personal acquaintance, and distinguished some with his friendship, while he was careful also that their achievements should not go without those tokens of royal appreciation which their fellow-subjects would readily recognise. In the institution of the new orders associated with his reign of peace we find honours and decorations devised for the reward of those who in the exercise of peaceful pursuits, in literature, in science, in acts of charity, in the display of the virtues of citizenship, have deserved esteem by working for the good of their fellow men. Among the rewards thus distributed a fair share has fallen to members of the medical profession, and has helped to raise it to that position which it now holds in the eyes of the nation.

In reckoning that which the King who has passed from us achieved we must not forget the tireless energy which enabled him to perform the duties of his station as a prince and as a monarch while enjoying to the full the pleasures of life which that station placed within his grasp. He may be said to have lived in a stimulating age, and to have occupied with honour a position which enabled him to watch and to assist in no small degree the progress taking place around him. During the reign of QUEEN VICTORIA he saw many great changes brought about in the social and sanitary condition of the people, in promoting the public health, in housing the poor, in the cheapening of their food, in protecting them against injury in mines and in factories, and in the promotion of their general welfare. Of all these and kindred developments he was a sympathetic spectator; in some he took an active part, and he was ever ready to show appreciation and bestow recognition upon the work of others. At the same time, he filled the rôle of the leader of society in the kingdom, so that when he succeeded to the throne his popularity as a prince commended him to a large body of his subjects who then scarcely appreciated his higher qualities. In the encomiums passed upon him during the past few days he has been praised as a "popular" monarch. He deserved the title. In a nation priding itself upon the exercise of manly qualities he was conspicuous as a man, combining royal dignity with a genial courtesy to those brought into contact with him, enjoying pursuits and sports dear to his countrymen, and in no way removed from them by the pride of his position or by any asceticism of nature or temperament. His place in history, however, will rest upon far more than popularity, as the word is generally used. He will be recognised by posterity as the embodiment of social diplomacy—the man who wanted the world to be happy and who had the insight to know how to take steps in that humane direction.

———o———

Crime and the Weather.

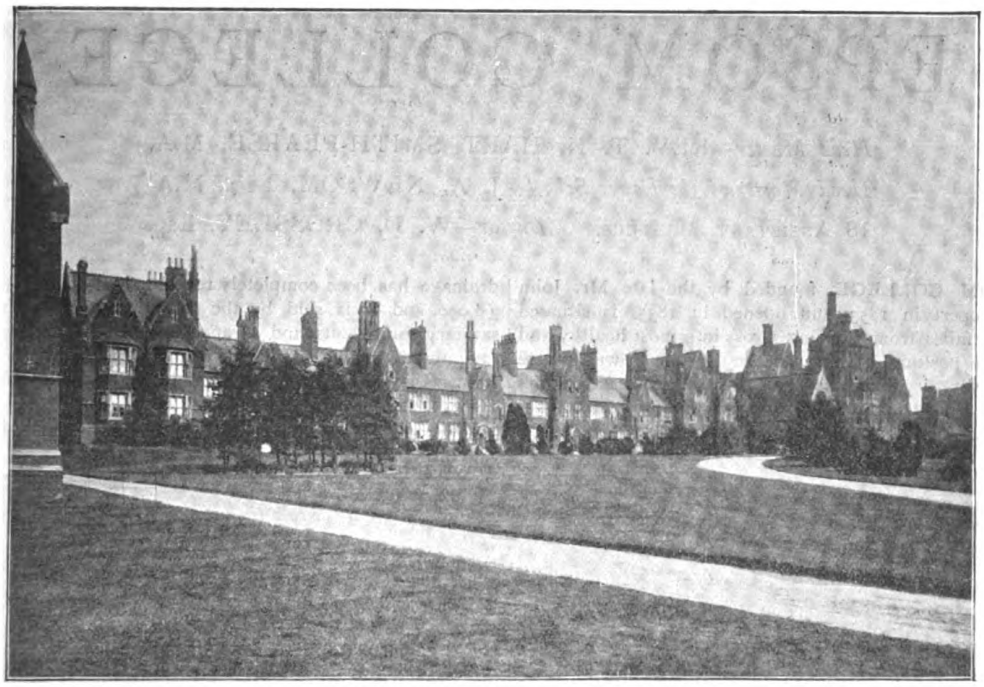
IN the scientific study of the criminal, which has been pursued with so much zeal and assiduity since the late Professor LOMBROSO brought it into vogue some 30 years ago, a great deal of attention has been devoted to investigating the relation of the various forms of anti-social conduct to meteorological conditions. The problem is, of course, by no means a novel one; it was discussed long before criminal anthropology was ever heard of, and its fundamental idea—that the mind is affected by atmospheric influences—dates back in all likelihood to the first stirrings of speculative thought. In less remote times and in more definite form it was a common subject of theorising ingenuity from the time when MONTESQUIEU formulated his brilliant, if occasionally fantastic, generalisations on the effect of climate on national manners and customs; and, in fact, the germs of many of the modern

views on this, as on other sociological questions, may be readily discovered by the curious inquirer in the neglected pages of the "Esprit des Lois." It was not, however, until much later - not, indeed, until the beginning of the statistical era, almost in our day—that the matter came to be susceptible of exact investigation, and that it was possible on the basis of adequate numerical evidence to establish the relation of seasonal and climatic changes to the movement of crime, and by comparing the variations in this movement in years differing in their meteorological character to gain some insight into the nature and significance of the relation of the two phenomena.

For the purposes of such an inquiry it is obvious that a special degree of interest attaches to those years in which the weather conditions, either in themselves or in their relation to other causal factors, show any decided difference from the average. Since the revision of the judicial statistics by Sir EDWARD TROUP in 1892—a reform, as we may remark in passing, which has given us the best criminal statistics in Europe—there have been several such years, and amongst them we may include as a particularly instructive instance the year 1908, for which the official returns relating to crime and criminal proceedings have just been published. Before discussing the figures given in these returns and considering them in relation to the meteorological character of the year, we may recall the fact that crimes of an impulsive type—and it is, of course, only such crimes that come into an inquiry of this sort—are specially frequent in the summer months; this is true of homicidal offences, of crimes of lust, and of attempts to commit suicide, and it is also true, of course, of actual suicide. While the fact is not disputed, there is a good deal of diversity of opinion as to its explanation. Some criminologists, and notably those of the Italian school, ascribe the greater incidence of passionate crimes in summer to the direct influence of the heat on the nervous system producing a condition of excessive erethism, while other observers regard it as merely a result of the longer days and the outdoor occupations which offer more opportunities for committing such offences. On the whole, the latter explanation has hitherto been the more generally accepted, largely on account of DURCKHEIM'S able advocacy of its validity in the case of suicide. There is, however, some reason to think that it should not be adopted as an exclusive theory, and that in order to find a complete explanation of the facts it is necessary to admit a certain share of influence through the direct action of temperature on the nervous functions; and it is as confirming this opinion that the criminal statistics of 1908 are of special interest. The year in question, it should be mentioned, was not only remarkable as one in which the climatic conditions were peculiarly of the sort to justify the Englishman's traditional habit of grumbling about the weather: it was also memorable in economic history for a marked depression of trade and an unusual amount of unemployment. That fact interests us here, because "bad times" by minimising convivial drinking tend to decrease one of the chief influences which affect certain impulsive crimes, and more particularly crimes of lust. In 1908 the industrial depression was, in fact, accompanied by a remarkable fall in the amount of drunkenness, bringing the figures for that offence to a lower level than any recorded in the past ten years. We may take it, therefore, that during the year drunkenness was much less operative than usual in the forms of delinquency which we are considering, so that the effect of any meteorological influences should be to that extent more perceptible.

Turning now to the examination of these influences, we observe as of most importance from our point of view that the autumn months, especially October and November, were relatively warm, while the summer months were relatively cold. The warmth of the autumn months was particularly notable, the mean temperature during October exceeding the average by more than 4° F. As these unusual conditions would not be likely to modify very largely the ordinary course of industrial pursuits, we are probably justified in concluding that any marked deviation from the normal incidence of impulsive crime in the months in question cannot be accounted for in this way, but must be attributed at least in part to the direct influence of temperature. And in the summer and autumn of 1908 the departure from the ordinary seasonal curve of crime was manifest: the daily average of crimes against morals in October and November, instead of being as usual about half that in the summer months, was as 3·3 is to 4·5, while a similar comparison in the number of attempts to commit suicide gives a ratio of 7·0 to 8·3, and in crimes of violence the daily average for the two seasons is actually identical. These figures will seem more striking when it is borne in mind that the month of August, which had an exceptionally low record of impulsive crime, included five Saturdays and five Sundays, an excess of holiday leisure which would be likely to furnish special opportunity for drunkenness and for the sort of misconduct that goes with drunkenness. The view which the exceptional features of the seasonal distribution of crime in 1908 would suggest—viz., that offences of the impulsive class are directly influenced by variations of temperature—is confirmed by the statistics of other years in which the climatic conditions were of an unusual type. In 1895, for instance, there was a period of most exceptionally severe weather in the early part of the year, the temperature in the month of February being the lowest recorded for 50 years; and coincident with this cold weather there was a marked diminution in impulsive crime; sexual offences and suicides during February fell to nearly half, and attempts to commit suicide to less than half the ordinary winter average. And the statistics of other meteorologically abnormal years point in the same direction. Statistical evidence of the kind which we have been considering must, therefore, make us hesitate to accept the view of those sociologists who would have us believe that climatic and seasonal variations can only influence crime through the modifications which they produce in social and industrial activities. In this, as in other matters, the individual is not yet entirely swallowed up by the social man.

INVALID CHILDREN'S AID ASSOCIATION.—The Royal Family have again sent from Sandringham a gift of flowers to be distributed to the invalid children under the care of the Invalid Children's Aid Association.



Epsom College.

THE love of retrospection is inherent in the hearts of many persons, and this quality has prompted us, as it has prompted the editors of other old-established journals, to print habitually brief extracts from the back numbers. Our column entitled "Looking Back" is usually dated 78 years ago, which is a forcible testimony to our longevity, but which practically precludes anyone who is alive ever having seen the quoted article when it first appeared. This week we only look back 59 years, when we suggest that those of our readers who are interested in Epsom College should peruse the extract from a leading article of May 3rd, 1851, and should compare the opinion and hope expressed therein with the facts given in the prospectus of the College which we print in a prominent position in this week's issue. The comparison will serve to recall to mind ARISTOTLE'S aphorism: "There is a charm both in our recollections of the past and in our hopes for the future." It would be difficult to find a more hopeful augury for the position which Epsom College will take amongst the public schools of our country half a century hence than the conspicuous success which has attended the school since its real foundation 55 years ago. We stated in 1851 that the college, then only in the stage of a plan in preparation, ought to give to distinguished scholars the means of proceeding to the universities and there earn some of that fame and emolument which then almost seemed the prescriptive rights of the other professions. It will be observed, on reference to to-day's prospectus, that 19 scholarships, many of which are held at the Universities of Oxford or Cambridge, are now available at the school, four of the value of £60 a year, five of £50 a year, and the others ranging in value from £25 to £40 a year. We further expressed the opinion that with right opportunities the intellect of the youth of medical parents would win triumphs conferring lustre on the entire profession. That this forecast has been fulfilled will be granted when it is perceived that in the last 16 years no fewer than 30 open scholarships have been gained by Epsom boys at the Universities of Oxford and Cambridge, and in addition 124 boys have won higher certificates of the Oxford and Cambridge Schools Examination Board, 200 have passed the matriculation examination of the University of London, 65 have passed the whole of the preliminary scientific examination for the degree of M.B., B.S. of the University of London, 60 have passed a part of that examination, and 157 have gained certificates in the art examination.

Academic success has been accompanied by structural improvements. Within the last three years the Council has expended a sum of close upon £20,000 in extending the College buildings and in making numerous and much-needed improvements for the comfort of the masters, the boys, and the domestic staff. These extensions and improvements have not been restricted to any particular department, but in making them regard has been paid to the activities of a large public school in all directions. A large new building has been erected, which is known as the "Markham Skerritt Laboratories," containing physical and biological laboratories, lecture rooms, a workshop, a battery room, a day boys' common room, and four large and well-ventilated class rooms. The erection of this building has permitted an increase in size and accommodation of the chemical laboratory and theatre. Another new permanent large building is a gymnasium, which contains a fencing gallery and is fitted with all necessary up-to-date appliances, including those required for Swedish exercises. A music block has been erected containing sound-proof rooms for music practice and a suitable hall for concerts and classes. The Officers' Training Corps, which numbers at the present time 150 members, will appreciate the new armoury which has been provided, containing stands for 200 rifles, as well as the extension of the shooting range to the full regulation length. A large brick-built carpenter's shop, with a convenient timber store attached to it, has taken the place of the old iron structure in which good work was done for many years; and a building has been provided, containing a new box room, a changing room, and an extension of the lavatory accommodation. Most of these buildings are facing the College quadrangle, which the Council has very wisely had levelled and asphalted, and round which a handsome covered way has been erected, thus connecting the various new and previously existing buildings. The whole of the College has been heated by the "Reck" circulator system, and a hot water supply has been provided throughout the buildings, with the result, we understand, that there has been a marked freedom from colds generally. A few years ago a sum of about £8000 was expended in rearranging and modernising the sanitary arrangements at the College, and that the efforts of the Council to completely renovate the drainage were successful is proved by the expression of opinion by the Epsom urban authorities that the sanitary equipments and arrangements of the College now rank among the highest in this country.

We hope that any of our readers who have the opportunity will pay a visit to Epsom College. The school is not exclusively for the sons of medical men, but the medical foundation is an important part of the school's constitution. The advantage given to the sons of medical men of a reduction of 10 guineas in the annual fee does not, of course, make any great difference to the parental pocket in these days of profuse expenditure upon public school education, but the distinct success of Epsom boys when they enter the medical profession will appeal to those of our readers who intend to bring up sons to follow in their own footsteps. There is also the charitable side, and because we know how valuable this is we wish that many medical men would inspect Epsom College, and as an inevitable result become subscribers to the foundation. There can be no better object for endowment, nor one whose appeal is closer.

UNIVERSITY OF LONDON: UNIVERSITY COLLEGE NEW CHEMICAL LABORATORIES FUND.—The meeting at the Mansion House arranged for Tuesday, May 10th, in support of the fund for new chemical laboratories at University College, has been postponed on account of the death of His Majesty the King. It is anticipated that a meeting will be held later in the year, when a further announcement will be made as to the date.

EPSOM COLLEGE

Patron—HIS MOST GRACIOUS MAJESTY THE KING

President—THE RIGHT HON. THE EARL OF ROSEBERY, K.G.

Visitor—THE RIGHT REVEREND THE LORD BISHOP OF WINCHESTER

Treasurer—SIR HENRY MORRIS, BART., F.R.C.S., M.A.

Vice-Presidents:

THE EARL SPENCER, K.G.
THE LORD LISTER, O.M., F.R.S.
SIR TREVOR LAWRENCE, BART.
RIGHT HON. A. J. BALFOUR, M.P.
SIR CONSTANTINE HOLMAN, M.D.
R. GOODING, ESQ., M.D., J.P., D.L.
S. FELCE, ESQ., M.R.C.P. EDIN.
F. DE HAVILLAND HALL, ESQ., M.D.

Members of the Council:

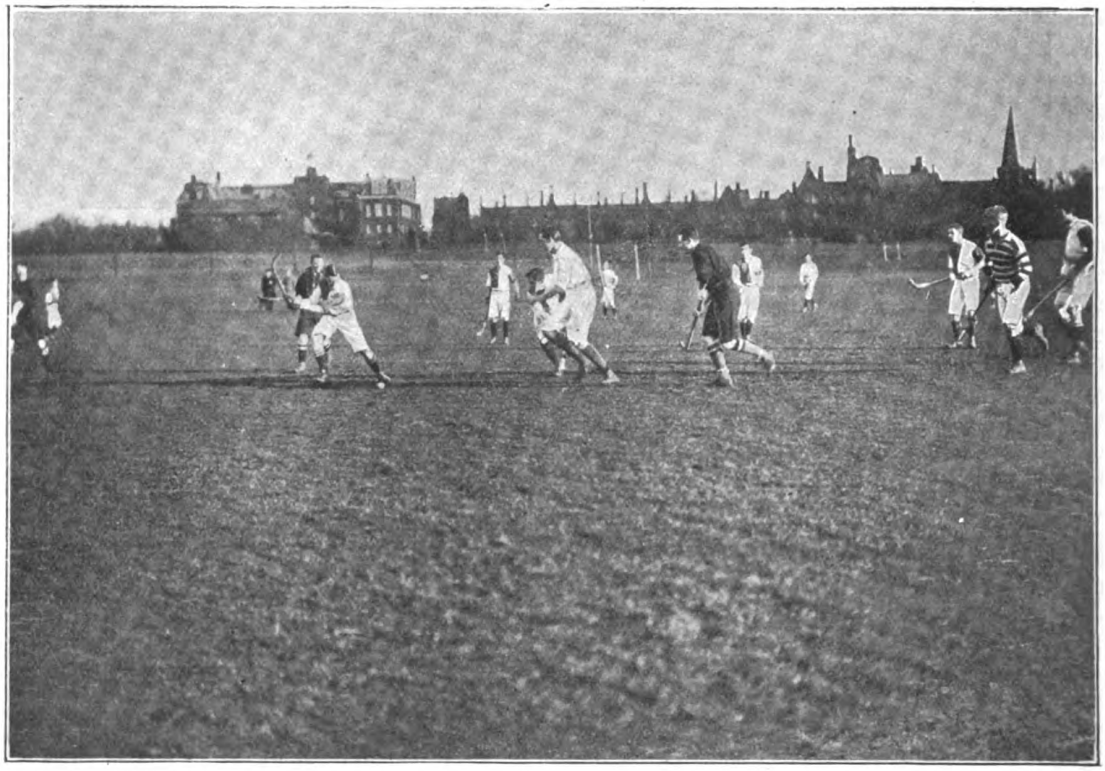
THE PRESIDENT, THE TREASURER, AND THE FOLLOWING—

SIR W. S. CHURCH, BART., K.C.B., M.D., *Chairman*. REV. E. W. NORTHEY, M.A., *Deputy Chairman*

BLOXAM, J. ASTLEY, ESQ., F.R.C.S.
BOYD, STANLEY, ESQ., F.R.C.S.
BRADFORD, J. ROSE, M.D., F.R.S.
BUSH, J. PAUL, ESQ., C.M.G.
CALDECOTT, CHARLES, M.B.
CLARK, ANDREW, ESQ., F.R.C.S., D.SC. OXON.
COLLIER, W., M.D.
DRAGE, CHARLES, M.D.
EVE, F. S., ESQ., F.R.C.S.
GODSON, CLEMENT, M.D.
GOULD, A. PEARCE, ESQ., M.S., F.R.C.S.
HALL, F. DE HAVILLAND, M.D.
HASLAM, W. F., ESQ., F.R.C.S.
HOLMAN, SIR CONSTANTINE M.D.
KIALLMARK, H. W., ESQ.
MAKINS, G. H., ESQ., C.B., F.R.C.S.
MORGAN, JOHN H., ESQ., C.V.O., F.R.C.S.
NEEDHAM, F., M.D.
PAGE, ERNEST, ESQ., K.C.
PAGE, HERBERT W., ESQ., F.R.C.S.
POLLARD, BILTON, ESQ., F.R.C.S.
POWELL, SIR R. D., BART., K.C.V.O. M.D.
PROPERT, W. A., ESQ., B.A.
RANKIN, GUTHRIE, M.D.
SMILES, CLEMENT L., ESQ.
TAYLOR, FREDERICK, M.D.
THOMSON, J. ROBERTS, M.D.
TIRARD, NESTOR, M.D.

Honorary Consulting Physician—FREDERICK TAYLOR, M.D., F.R.C.P.

Honorary Consulting Surgeons—SIR HENRY MORRIS, BART., F.R.C.S.; BILTON POLLARD, ESQ., F.R.C.S.



Honorary Consulting Dermatologist—SIR MALCOLM A. MORRIS, K.C.V.O., F.R.C.S. EDIN.

Secretary—J. BERNARD LAMB, ESQ.

EPSOM COLLEGE

Head Master—REV. T. N. HART SMITH-PEARSE, M.A.
Head Master of the Lower School—J. A. NEWSOM, ESQ., M.A.
18 ASSISTANT MASTERS. *Bursar*—W. D. CROSSLEY, ESQ.

EPSOM COLLEGE, founded by the late Mr. John Propert in 1853, and opened in 1855, is situated 15 miles from Charing Cross in a most healthy and picturesque position, high up on the Epsom Downs, where the air is very dry and bracing. The College stands in its own estate, consisting of over 80 acres: in front of the main buildings are large ornamental grounds in which the Chapel forms a conspicuous feature, and there are beyond large playing fields of over 26 acres, well adapted for cricket, football, and all other games. There are also several good fives courts.

View of Epsom College, with Lower School to the left and Playing Fields in front.

There is an experienced Matron in the College and another in the Lower School, from whom the boys respectively can always obtain advice and guidance. There is also a Resident Matron at the Infirmary, which is a detached building within the College grounds containing about 40 beds. There is a Laundry attached to the College, complete in every detail of machinery for washing and drying flannels as well as all other articles of clothing.

The closest attention is paid to the sanitary arrangements at the College, which are under the supervision of a permanent Sanitary Inspector. Within the last few years the drainage has been completely renovated at a cost of over £8,000, and it is said by the urban authorities that the sanitary equipments and arrangements of the College now rank among the highest in this country. The water is drawn from a well on the premises, sunk in the chalk, and analysis shows it to be of the greatest purity.

The College can accommodate over 350 Resident Pupils, 50 of whom are Foundation Scholars. If the sons of Medical Men, pupils are charged 65 guineas a year for education, board, lodging, and washing; and if not the sons of Medical Men, they are charged 75 guineas a year for the like advantages.

The School is not exclusively for the sons of Medical Men; boys belonging to other professional and to the higher commercial classes are also educated here. There are a certain number of Day boys, and in order to give facility for their attendance the School hours have been so arranged as to enable them to come by the train reaching Epsom Downs at 8.54 a.m., and to leave by the 6.27 p.m. train. The Fee charged for Day Boys is 25 guineas a year.

A few Exhibitioners—sons of duly-qualified Medical Men being, in the opinion of the Council, among the less fortunate

members of the profession—obtain their education for 35 guineas a year.

Boarders are taken by the Head Master; and a few, who must be under fifteen years of age, are received in the house of Mr. E. Norman Gardiner.

The Lower School is a large building, distinct from the College buildings but within the College grounds. Here all Junior boys, whether members of the several masters' houses or day boys if in the lower forms, are kept entirely separate from the main body of the school, both for work and games. These boys are grouped into two "Houses" under the care of experienced Masters, where they remain until moved up into the Middle School.

The School is divided for teaching purposes into three sections, termed the Upper, Middle, and Lower Schools. The Lower School, as just stated, is entirely separate, and ends with the Upper Third Form. In the Middle School, from the Middle Fourth Form upwards, Greek is taught on the Classical side and German on the Modern. In the Upper Classical School boys are prepared for the Universities and the learned professions, and on the Upper Modern side for the Army, Navy, Civil Service, Engineering, and for Mercantile careers. The School has recently been inspected under the Board of Education, and permission has been obtained to send in candidates for leaving certificates, qualifying for the Army. Boys can thus be prepared for Woolwich or Sandhurst, or similar examinations. Science is taught in each of the forms, elementary instruction therein being given in the Lower School. French is taught throughout the School.

Geometrical Drawing and Freehand Drawing may be learnt in any part of the School; in the Lower School the latter is compulsory.

Particular attention is paid to the teaching of Natural Science, for which there are several well-appointed Laboratories and two Lecture Theatres. The College has been recognised as a "School of Science" by the Conjoint Board of the two Royal Colleges of Physicians and Surgeons, and students are prepared for Parts 1, 2, and 3 of the First Examination for the Diplomas of those Colleges. There are also special classes for the Matriculation Examinations of the University of London, and for the First Examination for Medical Degrees (Preliminary Scientific) of the same University.

Great attention is given to the cultivation of Music and Singing, and a building containing a series of practice rooms and a concert hall has recently been erected.

There is a Natural History Society for the cultivation of the scientific observation of living plants and animals; lectures are delivered and papers are read and discussed at the meetings of this Society, and a full report of the proceedings is published annually.

There is a Botanical Garden for the use of students; and a Debating and Literary Society, managed by the Senior boys.

The Propert Library and Reading Room is open to members of the Upper School. In this room there is a Museum of Natural History.

The Holman Art and Reading Room is open in recreation hours.

There is a chapel for Divine Worship, according to the ritual of the Church of England.

There are two fine Gymnasia; an Instructor is always present. Every boy below the Upper School must attend for gymnastic exercises. The drilling hours for the Lower School are so arranged as to make a break in the morning's work.

There is an Officers Training Corps, which has a Drum and Bugle Band, and numbers 150 members.

The playing fields are large and excellent in every respect; and all the boys, if their physical condition permits, are expected to join in the games.

There is also a Fire Brigade, under a Master's charge, and the boys are drilled in the use of the appliances against fire, with which the building is fully provided. There is a good Manual Fire Engine.

SCHOLARSHIPS

Nine Medical Scholarships at the Hospital Schools in London, ranging in value from about £120 to £150, are competed for annually, and there are two "Ann Hood" Exhibitions of 12 guineas restricted to the Senior Modern Form. There are certain Junior Scholarships of £30 a year, tenable during period of residence at the School, which are competed for in March of each year, open to Candidates whether they have already entered the College or not. Two Senior Scholarships of £21 are awarded to boys already in the School. There are two "Haviland Exhibitions" to Cambridge University of £60 a year for four years for proficiency in Natural Science; and there are valuable Scholarships for boys proceeding to the Universities of Oxford or Cambridge—*viz.*, three "Forest Exhibitions" of £50 a year, and one "Armstrong Scholarship" of £60 a year for Classics, all being tenable for three years: the "Anstie Memorial Scholarship" of £40 a year for four years, and the "Leach Memorial Scholarship" of £30 a year for four years; the "Harvey Owen Scholarship" for Science of £50, the "Doncaster Gift Scholarship" of £25, and a "Da Silva Scholarship" of £50. A "Stone Scholarship" of £25 is awarded annually, and a "Jenks Memorial Scholarship" of about £27, tenable for five years, is given annually, *by preference to Students of Epsom College*, on the nomination of the Royal College of Physicians and the Royal College of Surgeons, alternately. A "Du Pasquier Scholarship" of £60, tenable for three years, is awarded every third year to a Foundation Scholar, and a "Highett Scholarship" of £30 a year is given to a pupil in need of assistance to pursue the study of medicine.

The following Successes have been Gained since 1893

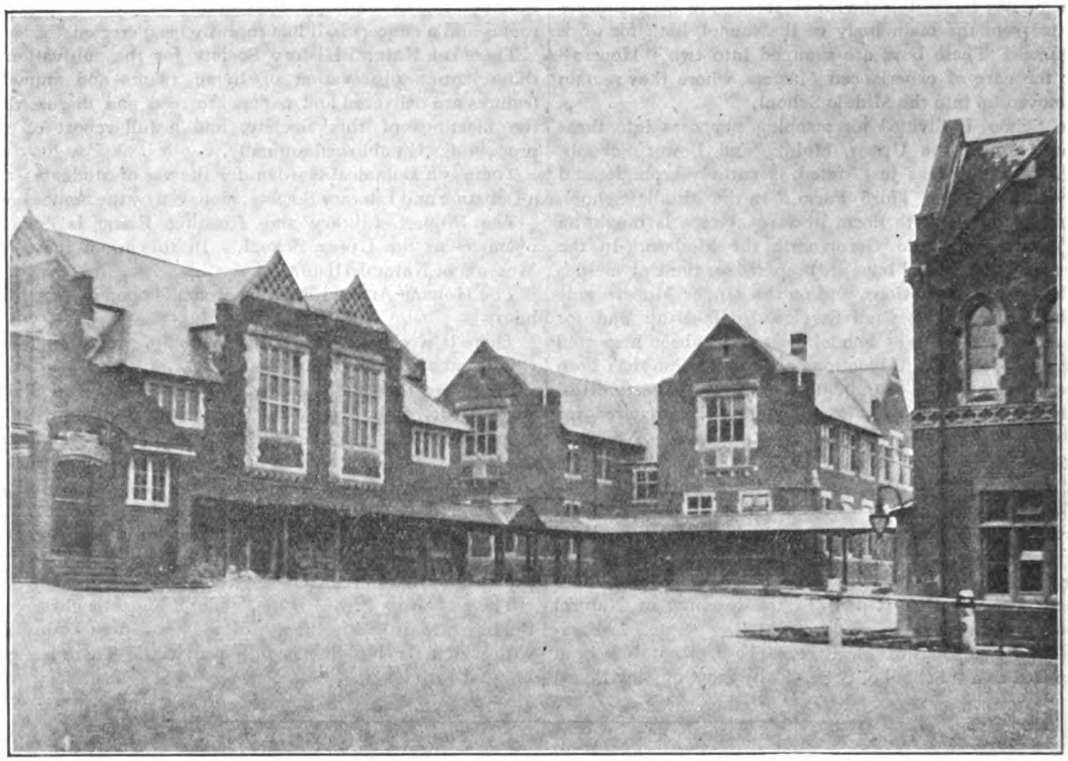
30 Open Scholarships at the Universities of Oxford and Cambridge.

124 Higher Certificates of the Oxford and Cambridge Schools Examination Board, with 31 distinctions.

390 Lower Certificates of the Oxford and Cambridge Schools Examination Board.

200 boys have passed the Matriculation Examination of the University of London.

65 boys have passed the Prel. Scientific Examination for the Degree of M.B., B.S. of the University of London.



60 boys have passed a part of the Prel. Scientific Examination for the Degree of M.B., B.S. of the University of London.

9 boys have passed the Intermediate Science Examination.

157 boys have obtained Certificates in the Art Examination (Drawing).

In recent years one boy has gained the thirteenth place at Woolwich direct from the College, and has passed out of Woolwich into the Royal Engineers sixth on the list; another student has qualified as Volunteer Captain within a few days after leaving College; two boys have won the sword of honour at Sandhurst; two others have taken the Silver and the Bronze medals of the Public Schools Gymnastic Competition; and several old boys have played in County Cricket matches.

No fewer than twelve old Epsomians hold important positions on the staffs of some of the principal London Hospitals.

The Newly-Asphalted Quad and surrounding Buildings (reading rom the left): The Holman Art and Reading Room, the Gymnasium, the Music Rooms, the "Markham Skerritt Laboratories" and Class Rooms, and the Carr Class Room. The new Carpenters' Shop is a large building, 74 feet by 22 feet, behind the "Markham Skerritt" block, and is not seen in this view.

RECENT ADDITIONS AND IMPROVEMENTS TO THE SCHOOL BUILDINGS

Within the last three years the following buildings have been erected, and other improvements carried out, at a cost of nearly £20,000:—

The "Markham Skerritt" block, comprising large new Physical and Biological Laboratories, with Lecture rooms, Workshop, Battery room, a Day Boys' common room, and four large, airy, and light Class rooms.

This new building has allowed of the improvement and extension of the Chemical Laboratory and Theatre.

A new large and most up-to-date Gymnasium with Fencing Gallery and Swedish Exercise appliances.

A new Music Hall for Concerts and Class teaching; and separate sound-proof Music Practice Rooms.

A new Armoury, with stands for 200 Rifles.

Extension of the Shooting Range to full regulation length.

A new Carpenters' Shop, with large timber store, &c.

A Building giving additional Box room, changing room, and Lavatory accommodation.

Heating installation throughout the whole of the buildings, new and old, on the "Reck" system.

Provision of complete Hot-water supply throughout the buildings.

The quadrangle has been extended, levelled, and asphalted.

A handsome covered way running round the quadrangle and connecting the whole of the numerous buildings.

School Lists, giving full information as to Scholarships, &c., with Prospectuses and Forms of Application, may be obtained on application to the Bursar, at No. 3 The College, Epsom, Surrey.

Annotations.

"Ne quid nimis."

POPULATION AND VITAL STATISTICS.

MEDICAL officers of health are now, nine years since the last census, seriously handicapped by the impossibility of determining with any approach to accuracy the present population of their sanitary areas, more especially in urban districts. The increase of emigration since 1901 and the increased facilities for locomotion, due to the rapid development of suburban tramways since that date, have undoubtedly reduced the rate of increase of population within the arbitrary boundaries of administrative areas. Consequently the official estimates of the present population of very many of our largest towns, based on the hypothesis of continued increase at the rate that prevailed between 1891 and 1901, are without doubt considerably in excess of the true numbers, and thus both the birth-rates and death-rates in such towns are now understated. In the city of Birmingham, for instance, the medical officer of health, in his report dealing with the first quarter of this year, adopts the Registrar-General's estimate of the population of the city in the middle of this year—namely, 570,113 persons; he remarks, however, "that this figure almost certainly exceeds the actual population, probably to the extent of 40,000 persons." Notwithstanding this expression of opinion, the trustworthiness of which there seems to be very little reason to doubt, the medical officer proceeds to state that the birth-rate in the city during the quarter under notice was "the lowest for any quarter on record," and that the death-rate "was the lowest ever recorded in Birmingham during the first quarter of any year." It is, of course, obvious that if the population of the city is overstated by 40,000, the annual birth-rate during the quarter is thereby understated by about 2 per 1000, and the death-rate by more than 1 per 1000. In many of the 77 largest towns in England and Wales dealt with in the Registrar-General's returns the present population is probably even more seriously overstated than is suggested as being the case in Birmingham. Those who appreciate the value of trustworthy vital statistics as a stimulus to health progress, and their number increases rapidly, find it exceedingly difficult to exaggerate the importance of providing some remedy for the dangers of untrustworthy population figures. The only true and satisfactory remedy for this defect is a more frequent census enumeration of the population of the United Kingdom. Sanitary authorities and medical officers of health should utilise all the influence they can command to secure in the Census Bills, now awaiting the consideration of Parliament, authority for holding in 1916 a simple intermediate census of the number, sex, and age of the population of the United Kingdom. The present depreciation of our national vital statistics, due to the fact that our population is now only enumerated once in ten years, is unquestionably standing in the way of continued health progress.

THE MUSICAL FLEA.

AT a recent meeting of the Royal Society Dr. A. E. Shipley read, on behalf of Professor F. J. Cole, a paper upon Tone Perception in Gammarus Pulex. The paper pointed out that audition in the lower animals cannot be satisfactorily studied in most cases, since a stimulus produces no response that can be seen or measured. Gammarus, however, when confined in a microscope live box, responds in an energetic and striking manner by flexing its first pair of antennæ under its body. A response can be elicited after the second pair of antennæ have been removed, but not after the removal of the first pair. The instrument generally used to produce the stimulus was a tenor trombone, and the experiments were conducted either on the ordinary laboratory table or on a table specially constructed to filter off vibrations from the ground, and thus to ensure that the stimulus reached the animal through the air. It was found that Gammarus was most sensitive to the B-flat below middle C, and that its range of tonal sense was so limited that it might almost be adduced as an example of absolute or physiological tonality—i.e., of an animal specially sensitive to one note. Only a small percentage of individuals, however, responded at all, and then, probably owing to fatigue, the power of response soon disappeared. One specimen responded to every note of the trombone. The experiments may be interpreted as either tactual or auditory reactions, if it can be held that these two senses have segregated out in such a simple and true aquatic species as Gammarus pulex, and do not merely form a part of an indefinite common sensibility. Professor Cole's experiments are of great interest, and it may be remembered that Darwin, in his great book on "Earthworms," pointed out that these animals were quite insensible to the sound of a bassoon. Those of our readers who have passed middle age may remember seeing at fairs and such-like occasions an exhibition known as the "Industrious Fleas." One of the industries which these little animals undertook was nominally that of playing in an orchestra, and this was managed by the fleas being tied to small paper chairs which were placed in a ring on a musical box. When the musical box was wound up and set going the fleas waved their legs in a perturbed manner, but this was, we presume, mainly a tactual reaction owing to the vibration of the musical box being transmitted through the lid to the paper chairs, and so to the fleas' body.

PLANE TREES AND DISEASE.

IN the *Times* of May 7th there appears under the above title an interesting letter from Lord Walsingham, in which he directs the attention of the public in general, and of the medical profession in particular, to what he suggests may be a serious cause of disease, particularly of the respiratory organs. He believes that plane trees, which are for many reasons so popular in London and other towns, give off minute spicules, which are very irritating to mucous membranes; indeed, he states that "wherever plane trees are abundant, colds, coughs, inflamed eyelids, throat troubles, and general irritation of the mucous membrane are more prevalent than where such trees do not exist." Lord Walsingham's attention was first drawn to this matter as long ago as 1892, when he noticed the condition of the road dust in the avenue of planes to the west of Cannes, and attributed a serious attack of pneumonia following severe bronchial irritation in a member of his family to this cause. Microscopical examination of this dust showed that minute spicules, formed by the breaking up of the fruit balls of the plane trees, were plentifully admixed with it. A search of the literature was made at Lord Walsingham's request by Dr. Henry, Reader in Forestry at the University of Cambridge, and it was found that in "Trees of Great Britain" a statement is made that "plane trees are prohibited by law from being planted near or around schools in Alsace Lorraine," and that in the *Gardener's Chronicle*, iii., 378 (1888), it is shown that Galen and Dioscorides knew of the irritating properties of plane trees. Dr. Henry found on exposing, during April, glass slides smeared with glycerine at Kew and in Berkeley-square, that

numerous particles of broken fruit spicules adhered, and he states that "the fruit hairs are jointed (some are branched) and break up and float in the air; there must be myriads of these spicules in the air near plane trees." Lord Walsingham concludes his letter in the following words: "The case is so far proved; but it remains to be confirmed by the discovery of these spicules in the air passages of human patients, and to this end I would invite the careful attention of the medical profession." We must confess that the evidence adduced is far from convincing, although there is nothing inherently improbable in the suggestion, since, as is well known, the pollen of Anthoxanthum odoratum is an important factor in producing hay-fever and hay-asthma in susceptible persons, and also that Primula obconica causes marked cutaneous irritation in certain people. It should not be very difficult to get evidence in regard to the possible irritating properties of the plane tree, and Lord Walsingham's suggestion will no doubt be carefully considered. Meanwhile, we may express the hope that the character of these trees will be vindicated, for they grow well in London and are in other ways a welcome addition to our streets and parks.

CHRONIC PRIMARY INTUSSUSCEPTION IN THE ADULT.

To the *Boston Medical and Surgical Journal* of April 7th and 14th Dr. H. W. Goodall has contributed an exhaustive paper on chronic primary intussusception in the adult. It is not sufficiently recognised, as he points out, that this condition may exist for long periods, extending from many weeks to years. For the first time he has collected and analysed the recorded cases. Previous writers collected and analysed cases of chronic intussusception, but their series included children and cases secondary to ulceration, tuberculosis, or tumours of the intestine. The symptoms in children, however, differ from those in adults, and the symptoms in primary cases differ from those in secondary cases, in which they may be modified or obscured by those of the primary disease. Dr. Goodall has collected 122 cases of chronic primary intussusception in the adult, and he thinks that the condition is not so uncommon as might be supposed, for in the great majority its existence was unsuspected, and the diagnosis was made only at the time of operation or necropsy. Often some grave abdominal condition such as tuberculosis or cancer was diagnosed, and operation was therefore deemed inadvisable. As a rule, the symptoms are of sudden onset and pain is the most frequent symptom; it takes the form of attacks of colic, at the end of which the pain disappears as suddenly as it has appeared—a point of great diagnostic value. The disappearance of the pain seems to be due either to sudden relief of the congestion of the invaginated part or to disinvagination; therefore it is more often observed early in the disease before adhesions have formed. In some of the cases the attacks subsided gradually. Early in the disease there are always intervals of freedom from pain between the attacks, but later, with the formation of adhesions and other pathological changes, slight or moderate pains may be present in the intervals. As a rule the intervals are short, varying from a few hours to two, three, or more days, but during them nausea, digestive disturbance, and abdominal discomfort may be present. In a few cases the intervals were long, varying from two weeks to a year. Then the diagnosis of recurrent appendicitis was often made. The attacks are excited by the ingestion of food, purgatives, enemata, manipulation of the abdomen, and muscular effort. The pain as a rule is not definitely localised and may be relieved or intensified by pressure. After pain, vomiting is the most frequent symptom; it occurred in about half of the cases. The vomit is in no way characteristic. Fæcal vomiting has seldom been observed. Constipation existed in only 42 per cent. of the cases and diarrhœa in about the same number. The severity of the diarrhœa varied; from 3 to 40 loose motions a day are recorded. The stools have been variously described as watery, watery stained with fæces, bloody, bile-coloured, black, and typhoidal. An offensive odour was usually noted. In the more severe forms of diarrhœa dysentery was diagnosed. In seven cases the stools were normal throughout the disease, though the course differed in no way from that of the other cases. Blood in macroscopic quantity was present in the stools in 83 per cent. of the cases. Mucus was present in about the same percentage. Symptoms of exhaustion occur early and are progressive when the intervals of freedom from symptoms allow only partial recovery from the attacks. Emaciation usually occurs and may be extreme. A flat or retracted abdomen is the rule; in most of the cases a tumour can be found at some time during the course of the disease; it is described as concave, cylindrical, or sausage-shaped. Changes in its size, shape, and position are frequent and are a most valuable sign. They are due to increase or decrease in the extent of the invagination, varying œdema of the intestine, or accumulation of fæces above the obstruction. Of still greater importance is the appearance and disappearance (from disinvagination) of the tumour at different periods of the disease. A tumour was present in the rectum in 12 per cent. of the cases. The mortality of cases not operated on is high—77 per cent. Surgical treatment is therefore indicated. The injection of air or water to reduce the intussusception appears to be useless, as adhesions, ulceration, or gangrene are usually present. In 47 cases treated by operation the mortality was 36 per cent. In 22 resection was performed with a mortality of 18 per cent. In 8 cases the bowel was disinvaginated with a mortality of 25 per cent. In 17 cases a palliative operation was performed with a mortality of 64 per cent.

APRIL AT HOME AND ABROAD.

THE weather of last month was colder both at home and on the continent than that of the corresponding month of last year. In most localities the difference in the temperature was very appreciable; at Paris it was as much as 6°, and at Biarritz and the Scilly Isles 5°, while along the south coast of England the difference varied between 2° and 4°. Nice, owing to many mild nights, was an exception, its mean temperature being more than a degree higher. In this country the general character of the weather, although very variable, was scarcely ever warm for the time of year, and seldom very cold during the night-time. The temperature of the days was, however, far below the April average—a result due to the great amount of cloud and the frequent cold winds. The sunshine, while it was not generally very much below the average for the month, was extremely meagre compared with that of April of last year, which, it will be remembered, was the brightest April on record. In London the number of hours (109) was less than half that during April, 1909, and at Manchester the difference was even more marked. The quantity of rain exceeded the average over the kingdom generally and also at many places on the continent, and days with more or less rain were many at most of the resorts represented in the table. In the metropolis, however, the total fall only just equalled the normal, and was less than during the brilliant April of a year ago. As is almost invariably the case the April weather in southern Europe and the Mediterranean region was much warmer than in any part of this country; at Nice and Lisbon the mean temperature

was about 9° above that on the south and south-west coasts of England, and at Rome and Naples 10° above, while at Algiers the difference was no less than about 14°. At Algiers, as well as at Malta, the nights were as warm as the days in the south of this country. The coast of Italy had about the same warmth as is usually experienced during the early part of June over the southern and central counties of England. It will be noticed that at Biarritz the temperature was much lower than at the other southern resorts both during the day and night, and that the weather was very rainy, rain falling on no less than 18 days. In common with the south-western corner of France generally it was unusually subject to cold northerly and north-westerly winds which brought much cloud and rain. Several of its days were colder than in the south-west of England, and on many occasions the changes from cold to relative warmth and *vice versâ* as very rapid.

ACETONURIA IN INFECTIOUS DISEASES.

IN another column we publish an article by Dr. Alfred Harris on the Occurrence of Acetonuria in Cases of Infectious Diseases. It has hitherto been considered that acetone appears in the urine in all fevers, and that it has therefore no great clinical importance.[1] Dr. Harris found, however, from an examination of the urines of patients in the isolation hospital at Southampton that, although this substance was present in most of the cases of scarlet fever and diphtheria which were admitted, as regards enteric fever it was found only in about a third of the cases. He further made the interesting observation that acetonuria occurred in many cases of diphtheria in which no rise of temperature had been noted; he therefore suggests that some other factor than simple pyrexia must have been concerned. He is also of opinion that the presence or absence of acetonuria has some clinical value as a symptom, since it was much more constantly present in diphtheria and scarlet fever than in cases of ordinary sore-throat, and thus its detection might be of assistance in differential diagnosis. Formerly it was believed that an abundance of nitrogenous food tended to its production, and some authors maintained that it arose from decomposition of proteids both of the body and of those taken as food. More recently, however, it has been shown that the essential factor in causing acetonuria is the absence of proper carbohydrate metabolism. Deprivation of food or the exclusion of carbohydrates from the food causes acetonuria without exception in the case of man. The fats also yield material necessary for the formation of acetone bodies. As Dr. Harris points out, if this explanation be correct, it seems strange that in a disease like enteric fever, when there is diminished absorption of food, acetonuria should only occasionally be met with, and then only at the beginning of the disease. These considerations are of interest and merit further investigation. Our knowledge of metabolism has greatly advanced during recent years, but many points still require elucidation.

THE LONDON COUNTY COUNCIL AND THE EARLY TREATMENT OF MENTAL DISEASE.

THE Asylums Committee of the London County Council has submitted to the Council itself the draft of a Bill to seek powers to establish and maintain a "receiving house for the early treatment of persons alleged to be insane." The committee at the same time recommended that the Council should not limit its application for powers to one receiving house, but should put itself in a position to provide whatever accommodation might be found necessary. The Finance Committee, in reporting upon the proposals of the Asylums Committee, pointed out that by them the Council would be committed to a new policy as regards the early treatment and certification of lunatics, a policy which would involve considerable expenditure of unknown amount. On general and financial grounds the Finance Committee opposed the recommendation of the Asylums Committee as to the larger scheme of receiving houses.[1] The subject has still, we believe, to be debated in the Council. We cannot regard the term "receiving house," used in this connexion, as a very happy one. The essential need in this particular matter is that there should be established as speedily as possible a mental hospital at which the earliest stages of mental disorder and the acute psychoses of short duration may be treated, and which may form an object lesson to the public in general, and to the presently constituted lunacy authorities in particular, that mental disorder may be investigated and treated as may any other class of ailment, and that it does not involve semi-disciplinary seclusion under lock and key under the direction of "keepers" of the nature of prison governors with a tinge of the medical man about them. It is a source of regret to us that the large general hospitals have not hitherto seen their way to devoting a ward or even a few beds here and there to this particular form of disease. We believe that there is no reason, from a medical point of view, why this should not have been done. So, too, it has always been a matter of some surprise to us why those hospitals especially devoted to the treatment and study of nervous disorder have not developed any sort of department reserved for the closely allied mental disorders; perhaps financial and administrative reasons have prevented this. There remain the

[1] THE LANCET, May 7th, 1910, p. 1231.

special wards of the infirmaries, and we think that these might be regarded as more than mere rest-houses on the way to asylums. They might be made suitable for the reception of the class of patients we have in mind and be placed under the consulting charge of practising psychiatrists. With another recommendation of the Asylums Committee, that every alleged lunatic should go in the first place to a receiving house, we do not altogether sympathise. There are many patients who come under observation too late for treatment at a mental hospital adapted for the class of patients we have above mentioned, and for whom the asylum is the proper place. It appears to us to be of little advantage that the journey to the asylum should be interrupted for a few days' purposeless sojourn at a receiving house, where the presence of such patients would involve arrangements wholly inappropriate to the atmosphere of the mental hospital.

THE DILUTION OF MILK WITH SPECIFICALLY CONTAMINATED WATER.

THE addition of water to milk is not such an exceptional occurrence as to call for special reference in these columns, but when the water which is added is not only grossly polluted but is found to actually contain the organisms of enteric fever the affair assumes a special importance. A case has recently come to light near Preston in which water to the extent of 3·6 per cent. had been added and in which the county analyst discovered the enteric fever organisms. The milk itself as drawn from the cow's udder was of excellent quality, but the water separately analysed yielded enteric fever bacilli. The bench quite rightly took a serious view of the offence and the defendants were mulcted in all to the extent of £44. A case such as this should turn the attention of local authorities and their officers to the enormous importance as regards health of securing a pure water-supply for dairies and cowsheds, but we are afraid that, especially in rural districts, this question does not receive the attention which it deserves. The position of the wells supplying many dairies in rural districts is often such as to actually cause pollution, and this although the dairies may have been registered with the local authority for many years. There can be no doubt that the standard of cleanliness of cowsheds in rural districts is far lower than it ought to be, and, although the milk cans are commonly washed with water which has been boiled, the utensils in which the cans are sometimes washed and those in which the milk is drawn are not infrequently used for other purposes. Water added to milk by way of dilution seldom undergoes any treatment whatever. In connexion with this important subject we are glad to see that a Milk and Dairies Bill [No. 123], providing for reforms with respect to the sale of milk and the regulation of dairies, is being introduced into the House of Commons. Whatever may be its fate it will have some educational value, and many of its provisions represent a distinct advance on the existing general conditions. Amongst other things the Bill provides for the compulsory registration of dairymen and a penalty not exceeding £5 for failure to register, and the local authorities are empowered to refuse registration as well as to remove from the list dairies already registered. Procedure with regard to the inspection of dairies and the prohibition of the supply of milk is simplified, and advances are made upon Section 4 of the Infectious Diseases (Prevention) Act, 1890, Section 71 of the Public Health (London) Act, 1891, and the Milk Clauses incorporated in many local Acts. With respect to tuberculous milk power is given to the local officers to require a cow to be milked in their presence, and the milk from any particular teat must, if so desired, be kept quite separate. A penalty is also imposed where the dairyman and those in his employ refuse to assist the officers in their investigations, a provision which in practice would prove decidedly useful. Similarly, as regards the sale of tuberculous milk or the use of such milk in the manufacture of products for human consumption, a fine of £10 is imposed unless proof is forthcoming that the milk has been boiled or otherwise sterilised. But this proviso as to sterilisation is obviously open to criticism. Greater facilities are afforded under the proposed legislation for procuring samples of milk, and power is conferred upon the Local Government Board by agreement with the Board of Agriculture and Fisheries to make any necessary orders as regards certain specified particulars, amongst which we note the prevention of impurities in milk, the cleanliness of milk vessels, the prohibition or regulation of preservatives, the identification of churns, and the prohibition or regulation of the mixing of the milk in one churn with the milk in another. The duty is also imposed upon the Local Government Board of making regulations under the Public Health (Regulations as to Food) Act, 1907, as regards the importation of milk or milk products; and the Board may, after holding a local inquiry, make orders compelling a council in default to do its duty as regards the milk-supply. Presumably the provisions of this Bill would have the effect of enabling the existing regulations under the Dairies, Cowsheds, and Milkshops Order to be replaced by something more modern and workable, and, if this alone were procured, a substantial step forward would be taken. In many instances the existing regulations are so vague and difficult to interpret that they possess very little practical utility from an administrative point of view.

MEASLES AND THE POST-OFFICE AUTHORITIES.

WE have received a copy of a report presented to the Brixham urban district council by Mr. George Blacker Elliott, the medical officer of health, concerning the action of the Post-Office authorities in regard to a case of measles occurring in the family of a postman. Briefly stated, the facts as reported by Mr. Elliott are that on April 15th the wife of a postman was taken ill with measles. On being informed of this next day, Mr. Elliott saw the postmaster and advised him to order the man off duty, so as to avoid the danger of infection. The postmaster stated that he had no power to do this, and accordingly Mr. Elliott telephoned to Torquay, where the head office for the district is situated. The officials there replied that they had no power to suspend the postman from duty, but promised to communicate with the authorities at the General Post Office. Three days afterwards the postman was ordered back to duty, and he has continued at his work from that time. Mr. Elliott has since learnt that the rule of the Post Office authorities is to the effect that no Post Office employee can be absent from duty on account of his coming from a household infected with measles. This is the more remarkable in view of the fact that there are stringent regulations barring employees from work if there is either scarlet fever or enteric fever in their homes. In commenting upon this case Mr. Elliott rightly maintains that it is not merely a matter of local interest, but one affecting the public health of the whole kingdom. Measles, as he points out, is by no means a trivial disease, when it is remembered that the deaths in England and Wales alone have varied during a period of 30 or 40 years from 6000 to 14,000 in a year. It is, moreover, one which is readily spread by fomites, and there is every reason to believe that letters, telegrams, or postage stamps may act as infective agents when handled by a person who has been attending on a patient suffering from the disease. Moreover, the

apparent indifference of the authorities towards this disease, when contrasted with their stringent action in regard to scarlet fever and enteric fever, is not calculated to inculcate the taking of any precautions on the part of their employees. There is, unfortunately, in the minds of many people a conviction that measles is not a serious disease and that its occurrence in childhood is almost inevitable. This is a pernicious doctrine, and, although apparently it has the tacit sanction of the postal authorities, it is contrary to the general principles of preventive medicine and to the best interests of public health. Mr. Elliott, in concluding his report, expresses the hope that his council will be able to arouse public opinion in regard to this matter, with a view to induce the postal authorities to alter their regulations. We are in complete sympathy with his action, and we share his surprise at the rule of the authorities in regard to measles. There are probably few people with families who would not be indignant if they knew that letters and other postal matter sent to them were handled by any person attending upon a case of measles, and who would not demand that those responsible for the working of the postal department should protect them and their families from an avoidable danger.

THE MEDICAL CURRICULUM AT THE UNIVERSITY OF EDINBURGH.

ONE of our Scottish correspondents gives this week a summary of a report submitted to, and approved by, the General Council of the University of Edinburgh on the medical curriculum. The report is the work of a small committee which was presided over by Professor E. A. Schäfer. The report has been forwarded to the University Court, and it lies with that body to determine what alterations are to be made and what alterations it is at liberty to make without applying for a new ordinance. It is one of the anomalies of University affairs in Scotland that the universities are hidebound by ordinances, and cannot move outside a given groove without the sanction of the sister universities. The recommendations of the report are in various respects commendable. The proposal to enable students to pass anatomy and physiology at the end of the second year and the suggestion to institute a block at that point are sound. Meanwhile, it is doubtful if the University can legally enforce such a block; but its application would do much to sift out unfortunates, and would prevent students nominally attending classes where they can only be a drag on their teachers and their fellows. The possible hardships of the block system have been thoroughly considered in debates at the General Medical Council and have been found to be exaggerated. The value of a scheme of education depends, however, very largely on the manner in which instruction is given, and the extent of ground which it is attempted to cover and which the student is expected to master. This is very true as regards such subjects as, say, chemistry, anatomy, and physiology. The temptation to the professor or lecturer is great to give instruction that is more suited to graduates than to young men being introduced to what is to them a totally new subject, and the standard of teaching naturally becomes the standard of examination, for in Scotland the teacher is also examiner. If the lecturer is content to cover, say, the physiology of the different systems, so as to give the student a foundation on which clinical teaching can be built, eight months' instruction is ample; but if more is attempted the result is that the student may never attain the sense of proportion or of perspective which it is desirable he should acquire; that he knows perhaps one system almost elaborately and another, equally important, most unsatisfactorily. A student might be able to take excellent muscle tracings and not be able to test for sugar in the urine or to determine the proportion of hæmoglobin in blood. There is a student's side as well as a professor's side to university education, and if the student can reasonably be expected to acquire an intelligent knowledge of subjects like chemistry and physiology in a few months it is of the first importance that general principles should be taught and only such detail as is necessary for an intelligent understanding of function. The systematic lecture is the traditional glory of the Scottish universities, and there is much to say in its favour, but the danger is that the lecture either degenerates into a dictation exercise and semi-coaching system, or rises quite above the level of the junior student. In a large teaching institution much depends upon the manner in which the junior student is introduced to the different subjects a knowledge of which he has to acquire. If teachers cannot bring themselves to this simplicity of attitude towards the student and take only their reasonable place in a teaching system, no scheme, however perfect it may look on paper, is of real value. Advanced instruction, research, and the extension of knowledge are the higher side of academic life, but ought to be kept clearly separated from the training of the average student, which is intended to make him a well-informed and intelligent practitioner of medicine, capable, however, of devoting himself later to any special department. We wish Edinburgh success in her efforts to improve her methods of teaching, and we shall await with interest the report which is looked for on the relations of the University, the extra-mural school, and the Royal Infirmary. That report ought to indicate the lines along which improvements in clinical teaching can be carried.

THE PROBLEM OF DISSEMINATED SCLEROSIS.

DISSEMINATED sclerosis is a common disease in this country, where it occurs with about three times greater frequency than in the United States. Next to tabes dorsalis it is perhaps the disease of the cerebro-spinal nervous system with which the practitioner is most familiar. The symptomatology of the affection, notwithstanding its various types, is in a characteristic case peculiarly easy of recognition; and its pathological anatomy, especially since the discovery of certain elective methods of staining, such as that of Bielschowsky, is well known. Its etiology, however, is still a problem of the greatest obscurity. The multiplicity of etiological factors enumerated in the average text-book is merely an indication of the poverty of our knowledge. To say that the disease originates in exposure to cold, in overwork, in strains, is to say nothing, when we remember that practically every nervous disease known to the medical profession has been attributed to the same causes. Oppenheim has with some reason suggested that metallic intoxications play a noteworthy rôle in the causation of the malady, yet it is quite impossible to consider these an etiological factor of universal applicability. Not a few cases have been reported where traumatism seems to have provided the starting-point of disseminated sclerosis, and these, in view of present-day legislation, are important; but if we are to seek a common etiological origin for the disease we cannot accept any morbid agents except those of widespread occurrence. On this ground it has been suggested that infective diseases precede the development of disseminated sclerosis with great frequency, notably typhoid fever and influenza. No doubt these conditions act by depressing the vitality of the nervous system and rendering it more vulnerable, but they cannot be considered as the primary causative instrument, for many patients present the characteristic symptoms of the disease who have never suffered from one or the other. It is a curious fact that post-partum debility not uncommonly provides the soil on which disseminated sclerosis develops; but again we must believe that the

patient's devitalisation allows some unknown morbific agent to attack the nervous system. There is, moreover, a disconcertingly large proportion of cases of this disease in which no antecedent exciting cause whatever can be traced; young patients who have lived all their lives in the country, under excellent conditions, and without having suffered from even so common a disease as measles, are often brought up to town hospitals with unmistakeable disseminated sclerosis. It seems, therefore, that we must either believe that a variety of causes can produce identical effects on the central nervous system or that we must look for some agent of a toxi-infective nature which has hitherto escaped identification. In this connexion it is of peculiar interest to record the fact that several recent examinations of cases of disseminated sclerosis have been more fertile of results. We need specify here only one—viz., that reported by M. Lejonne and M. Lhermitte in *L'Encéphale*, March, 1909. A young woman, aged 20 years, died after having exhibited the characteristic symptoms of the disease for five years. Plaques of sclerosis in every stage of development were found, from recent inflammatory foci to old areas of neuroglial sclerosis. The interesting fact is that all these recent foci surrounded a blood-vessel which remained patent, and that the affected area and the vessel walls were infiltrated with small round cells undoubtedly of inflammatory origin. It is legitimate to argue that this condition is highly suggestive of the action of some toxic or infective materies which is not apparently of the nature of ordinary pathogenic agents, inasmuch as it cannot be demonstrated by present histological methods, but which nevertheless is transmitted by the vascular system. The subject is a tempting one for further investigation.

THE DEATH OF PROFESSOR CANNIZZARO.

THE death of Professor S. Cannizzaro, which took place in Rome on Tuesday last, May 10th, at the ripe age of 84, recalls a time in the history of chemistry when considerable confusion prevailed as to atomic values, the confusion having been worse confounded by the fact that certain elements had more than one combining power. The great Italian chemist soon reduced matters to order in his classic thesis, "Sunto di un Corso de Filosofia Chimica," in which he threw light upon the methods employed for determining atomic weights. Above all he pointed out the great value of determining the vapour density of compounds, and he further showed how trustworthy as a confirmatory aid was the simple process of ascertaining the specific heat of elements. He was insistent upon distinguishing between atoms and molecules. Cannizzaro did much research work, he was joint discoverer with Cloëz of cyanamide, but was alone in the discovery of benzyl alcohol.

AN INTERNATIONAL CONGRESS ON THE CARE OF THE INSANE.

AN international congress concerning the care of the insane will be held in Berlin from Oct. 3rd to 7th. The congress will deal not only with questions referring to the modern treatment and the care of the insane, but also with measures and institutions for preserving mental health. An exhibition will be held in connexion with the congress and will include a history of the progress made in the treatment of the insane. The following papers will be read: On the Connexion between Civilisation and Insanity; Do Mental Diseases Increase in Number? on Sleeping Sickness; on the Care of Infants and Children as a Prophylactic against Epilepsy, Idiotism, and Mental Diseases; and Psychopathological Symptoms in Modern Art and Literature. For further particulars concerning papers and reports medical men are asked to apply to the secretary, Dr. Boedeker, Schlachtensee, near Berlin; concerning other matters to Dr. Falkenberg, Lichtenberg, Berlin, 79 Hernbergstrasse.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE following lectures at the Royal College of Physicians of London are announced to take place. The Croonian lectures will be delivered by Dr. F. W. Andrewes on Tuesdays and Thursdays, June 14th, 16th, 21st and 23rd, at 5 P.M. The Harveian Oration will be delivered by Dr. H. B. Donkin on Oct. 18th (St. Luke's Day), at 4 P.M., to be followed by the Harveian dinner at 7.30 P.M. The Bradshaw lecture will be delivered on Nov. 1st, at 5 P.M., by Dr. G. N. Pitt. The Fitz Patrick lectures will be delivered by Sir T. Clifford Allbutt on Nov. 3rd and 8th, at 5 P.M. The Horace Dobell lecture will be delivered by Dr. W. Bulloch on Nov. 10th, at 5 P.M.

THE THERAPEUTIC APPLICATIONS OF CALCIUM CHLORIDE.

IN view of the prominent place that has been given to the calcium salts by therapeutists during the past few years it is of interest to refer to a *résumé* of the therapeutic applications of calcium chloride by Dr. Moncany in a recent number of *La Clinique*. It has been employed more particularly in traumatic hæmorrhage, in purpura, hæmophilia, hæmorrhagic small-pox, and other hæmorrhagic diseases, and in hæmoptysis, in which its usefulness is a question of divided opinions. It has been given to increase the tonicity of the heart and vessels, in certain forms of headache, neuralgia, pruritus, eczema, and in urticaria. It has also been recommended in obstinate diarrhœa, epilepsy, laryngismus stridulus, convulsions, neurasthenia, hysteria, and mental alienation; its results in these cases are considered to be due either to its calmative or to its recalcifying action. Excellent results have been reported in the treatment of chilblains, acute œdema, serous effusions, œdema following vaccination, and viper bites. The eruptions that are liable to follow injections of anti-diphtheritic serum may in most instances be averted by the administration of a daily dose of calcium chloride on the day of the injection and the two following days. The dose of the calcium salt varies according to the quantity of serum injected, and must be increased when several injections are given. Dr. Moncany also refers to the use of calcium chloride in albuminuria, nephritis, pneumonia, tuberculosis, pregnancy, coryza, and rickets. The salt has been given by the mouth, subcutaneously, and per rectum. Wright found that the hypodermic method tended to cause sloughing. The intravenous method has been condemned on account of the supervention of thrombosis in experiments performed on dogs. Enemata containing calcium chloride are readily absorbed and are well borne by the patient. It is the usual practice to prescribe the calcium salts in small repeated doses, given by the mouth in dilute solutions. It is generally agreed that the treatment should be interrupted after a few days, as the continuous administration of the calcium salts tends to produce results which are just the opposite of those required. It is recommended to omit the treatment every fourth day, allowing a longer interval every eight or ten days. Calcium chloride must not be given to persons predisposed to calcic retention or atheroma, on account of which it is generally contraindicated in elderly persons, alcoholics, and persons suffering from lead poisoning. The best results will be obtained by cautiously administering the drug by the mouth, in small, divided doses, for brief periods with intervals of cessation. Calcium chloride may be combined with opiates in the treatment of hæmorrhage. Its intensely disagreeable taste has long militated against its employment. Perhaps

the best flavouring agents for masking the bitter, saline taste of calcium chloride are cinnamon and peppermint. Several formulas are given by Dr. Moncany, the simplest of which contains 150 grains of the salt in 10 fluid ounces of water, previously flavoured with syrup of peppermint. Two tablespoonfuls of the mixture are given for a dose. The following formula, devised by M. Roger, is fairly palatable: Calcium chloride, 60 to 90 grains; syrup of orange-peel, 10 fluid drachms; brandy, 1 fluid ounce; tincture of cinnamon, 1 fluid drachm; and water, 2 fluid ounces. Another formula, recommended by M. Peandelen of Nice, is probably the most satisfactory that has been devised: Calcium chloride, 90 to 120 grains; mucilage of acacia, 12 fluid drachms; tincture of cinnamon, 150 minims; water, 150 minims; and milk or almond emulsion, sufficient to make 6 fluid ounces.

IN consequence of the death of His Majesty King Edward, Patron of the society, no meeting of the Royal Society will be held until further notice. All meetings of the Royal Society of Medicine will be postponed until after the funeral. The President of the Royal Institution has decided that the lectures and evening meetings shall be discontinued until further notice. The annual dinner of the Royal Sanitary Institute, arranged for May 25th, has been postponed.

IN addition to the candidates whose names were mentioned in the last issue of THE LANCET, Mr. C. A. Ballance will, we understand, offer himself as a candidate at the approaching election of members of Council of the Royal College of Surgeons of England. An additional vacancy will be provided by the resignation of Professor G. A. Wright of Manchester before the termination of his term of office.

Alderman J. King Kerr, M.D., who has been chairman of the public health committee of the city of Belfast since 1904, has just resigned the position. The committee has passed a resolution recording on the minutes its sense of the loss it has sustained and its appreciation of the way Dr. King Kerr has discharged his duties.

THE next session of the General Medical Council will open on Tuesday, May 24th, when the President, Sir Donald MacAlister, K.C.B., will take the chair at 2 P.M.

UNIVERSITY OF LONDON: ADVANCED LECTURES IN PHYSIOLOGY.—A course of eight lectures on "The Mechanism of Coördination in the Central Nervous System" will be given by Dr. Gordon Holmes in the Institute of Physiology, University College, on Mondays at 5 P.M. The first lecture was delivered on May 9th. The syllabus is as follows:—Lecture 1.—Introduction. Coördination—definition. Structural and functional relationships of neurons. Spinal cord; arrangement of motor centres and distribution of afferent impulses. Lecture 2.—Spinal cord; internuncial and commissural fibres; grouping of the longer ascending tracts. Lecture 3.—Medulla oblongata and pons:—Arrangement of ascending tracts. Appearance of new centres and increase of associational system. Lecture 4.—Medulla oblongata and pons:—The labyrinth and the central connexions of the vestibular nerve. The formation of the cerebellar peduncles. Lecture 5.—The cerebellum; its structure; its afferent and efferent systems. The paracerebellar nuclei. Lecture 6.—The midbrain; its structure. The association of visual and auditory with other afferent impressions. Its descending tracts. Lecture 7.—The optic thalamus:—The terminal station of longer ascending tracts and of the ascending cerebellar fibres. The distribution of afferent impulses to the pallium. Lecture 8.—The cerebral cortex; differentiation and association of centres. The nature of the cortical motor centres and their connexion with lower centres.

SANITATION IN INDIA.

II.[1]

THE SANITARY REPORTS (*continued*).

THE review of the general aspect of sanitation may be compared with the health conditions and statistics of Bombay and Calcutta. The following were the comparative vital statistics in 1908:—

	Birth-rate.	Death-rate.
Bombay ...	32·4 per 1000	39·13 per 1000
Calcutta ...	20·1 ,, ...	32·3 ,,

Bombay.

With regard to the meteorological conditions here manifested, on the whole, a higher temperature in the earlier months prevailed than even in 1907. The maximum heat recorded (94·3° F.) was in April, the nearest approach to it being in March, 1901 (93·3°). The season was thus less favourable to the prevalence of plague, and accordingly we find that the disease gave the lowest figure recorded since its advent, for the total mortality was only 5361. This disease, however, was the cause of the greatest number of deaths, being followed in this respect by 2706 deaths from ague and remittent fever, by 1177 deaths from dysentery, and by 1026 from small-pox. Cholera only caused 95, and enteric fever 111 deaths.

Plague.—The most marked feature of the year's statistics is the diminished mortality from this disease, revealing an appreciable improvement on the record of the previous year. The total number of deaths yielded the rate of 5·48 per 1000. This is in marked contrast to the ratio per 1000 in 1903—viz., 26·78. The epidemic started later than usual and reached its zenith in April. The measures undertaken against the scourge were inoculation, rat destruction, evacuation, and disinfection. With respect to inoculation, although special and extended efforts were tried to popularise this method by lectures on the cause and prevention of the disease, and on the advantages of inoculation, yet the people did not respond sufficiently. In all there were 5894 operations performed during the year.

Dr. H. N. Choksy in his report on the serum-therapy of the disease shows the great importance of early treatment and the grave risk in postponing it till after the lapse of 48 hours. The mortality in cases treated in good time is from 15 to 25 per cent. better than in other cases.—It is held that with serum given early and in sufficient doses nearly every case of bubonic plague should get well, and that there is no reason to believe that the serum aggravated the disease when it was given to a patient actually ill with plague. Dr. Choksy also reports on the effect of extract renaglandin in the cardiovascular paresis of plague, which extract he considers in no degree inferior to adrenalin for the same affection, whilst it is cheaper.

With regard to rat destruction, 374,386 rats were killed in the different parts of the city; the ratio of the animals found infected was 12·3 per cent. Every place where an infected rat was found or where a plague case occurred was treated with pesterine, and, further, all gullies and passages between houses were similarly dealt with regularly. Evacuation was found to be a popular precautionary measure which did not even require persuasion.

Fevers.—These reached 3403, of which 2706 were referred to ague and remittent fever. During the third quarter of the year a wave of malaria severer than usual swept over India and included Bombay in its evil effects. A careful examination of different localities in the city revealed several breeding places for mosquitoes; these were treated by the filling in of all pools or the application of kerosene oil. The removal of rank vegetation, barrels, empty tins, and iron basins from the compounds was ordered, as also disused chattis, garden tubs, and other receptacles accumulating rain-water and thus affording breeding places for mosquitoes during the rainy season, more especially towards its close. It was pointed out also how extensive building operations, involving the formation of ideal sites for the collection of water, favoured the increase of mosquitoes. Attention was drawn to the bad influence of private wells, of tanks and cisterns when not properly attended to. The large areas of

[1] No. I. was published in THE LANCET of May 7th, p. 1289.

low-lying ground on the outskirts of the city which become flooded in the monsoon and form an ideal breeding ground for the mosquito were recommended to be drained or, if not, filled in. Storm-water drains were advised to be attended to, whilst the rain-sodden patches of ground near the overcrowded houses were recommended to be paved and drained. The use of prophylactic doses of quinine was strongly urged. Mosquito gangs were instituted but were unavoidably not sufficient.

Mr. P. B. P. Ghadially, in his report of the analytical and bacteriological work done in 1908, states that experiments were made with a view to finding some chemical which when added to kerosene oil or pesterine would confer a bactericidal power on them in addition to their insecticidal properties. After trying various disinfectants it was found that kerosene oil when mixed with cyanide of mercury (1 in 500) acquired the double efficacy of a pulicide and disinfectant, and therefore it would be an ideal disinfectant for plague, cholera, or enteric fever, amongst other diseases, as it would destroy microbes and fleas and would keep off flies.

The executive health officer, Dr. J. A. Turner, has produced an excellent report, and it is evident the health requirements of Bombay are well looked after.

Calcutta.

The report for Calcutta is furnished by Dr. T. Frederick Pearse, the health officer.

Cholera.—With respect to the various diseases causing mortality we find that cholera accounted for 3694 deaths, a larger rate, with the exception of 1907, than has been recorded for the last 20 years. Dr. Pearse makes some apposite remarks on the fact that notwithstanding the improved and increased water-supply for the city the death-rate from the disease has been during the last two decades as great as, if not greater than, it was previously, while the past ten years have shown a higher mortality than the previous decade. Cholera is universally recognised as due to polluted drinking water and the persistence of the disease can, by a process of exclusion, only be attributed to the water of the river, the canal, and Tolly's Nullah. The recurring outbreaks are not always indigenous in origin, but may be owing to the import of infected individuals from infected regions in Bengal, with the concomitant pollution of the water-supplies. The health officer likewise draws up an eloquent table showing the great influence of festivals on cholera mortality, and in illustration of this fact 30 instances are quoted since 1891. The explanation of these outbreaks of the disease is that the festivals are accompanied by a free use of the foul waters of the Hoogly and Tolly's Nullah.

An interesting section of the report deals with the subject of *biliary cirrhosis of infants*, a peculiar disease now for many years recognised in Bengal. Lieutenant-Colonel Gibbons, I.M.S., read a valuable paper on it at the Bombay Medical Congress of 1891. In 1907 there were 636 deaths from the disease in Calcutta, and 727 in 1908. The etiology is obscure; it is most likely a parasitic disease, but there is no evidence to show whether it is microbic or not. One theory holds it to be due to the absorption of toxic material from the bowel, but it can hardly be due to errors of diet, as it occurs in sucklings and artificially fed infants and in children between one and two years of age, who are given all sorts of food. Notwithstanding this the mortality from diarrhœal disease in children is 21 per 1000 births compared with 31 per 1000 births in England and Wales.

With regard to *small-pox*, the year 1908 was a moderate one, only 578 deaths being recorded. In December, however, there was a sudden rise in the mortality (91 deaths) from that of the previous month. This was the beginning of the outbreak of 1909. Dr. Pearse enters very fully into the principles governing prophylaxis. We wish, if there were the slightest chance of any result from their so doing, that the opponents of vaccination would read his remarks on the striking value of this beneficent measure. He holds up for approval and adoption by Government in all its offices, by the railway companies, and by all commercial houses the good example afforded by the Bengal-Nagpur railway. On this railway it is a rule that if an employee contracts small-pox, such employee will not receive full pay during the necessary leave unless he can show that the whole of his family have been revaccinated.

The number of deaths from *plague* in 1908 was less than that of any year since 1899. The incidence in every feature was similar to that of former years. Rat destruction was carried out on a large scale, and large numbers of dead rats continued to be found in the streets. Inoculation has been offered, but here again only few persons have taken advantage of it.

With respect to *malaria*, there were fewer deaths (1533) than in 1907 (1808) and 1906 (2113). The comparative freedom of the old town (urban Calcutta) still continues. The ratio was only 1·2 per 1000, as compared with 2·9 per 1000 in the suburban wards. This is evidently due to the more complete drainage of the old town and to the greater part of its surface being covered with a more or less damp-proof material. Owing to the absence of funds mosquito brigades were not employed until after the rains.

Enteric fever gave rise to 106 deaths amongst Hindoos and nine amongst Mahomedans.

Dr. Pearse draws attention to a peculiar disease, "Sutika," a form of chronic diarrhœa with fever that occurs in Bengal in puerperal women, and causes a considerable number of deaths. Its nature is obscure. It is certainly not dysentery, nor tubercle, nor ordinary puerperal fever.

Dr. Pearse in his able report draws attention to various other matters which space forbids us to enter upon. In conclusion, we will deal with his remarks on the present method of sand-washing, which as now carried on, he well says, is a dirty and disgusting practice, involving the possibility of an imminent danger to the community. The whole question was clearly and forcibly put before the corporation not only by Dr. Pearse but by the chief engineer; but the only result was "that the consideration of this matter be postponed for a year." That the method alluded to deserves the description of the health officer is apparent when we consider that it involves, amongst other features, undestroyed pathogenic organisms being retained in the sand; that men stand up waist high in the washing water with soiled clothes, and possibly suffering from mild forms of cholera, typhoid fever, or dysentery. The water-supply for the whole city might be contaminated. The chief engineer during the year submitted proposals to instal a battery of the Berlin type of sand-washer in order to do away with the manual cleaning. The water-supply committee recommended the corporation to sanction the estimate for this, which was accepted and tenders called for. These were then considered by the general committee with the above result! The present system remains a constant danger to the water-supply.

HOSPITALS AND DISPENSARIES.

The numbers of patients treated by the institutions below in 1908 were as follows:—

—	Number of dispensaries.	In-patients.	Out-patients.
1. Calcutta	19	28,456	298,448
2. Burma	233	50,274	1,085,744
3. North-West Frontier Province ...	33	10,198	654,763
4. Eastern Bengal and Assam	522	26,246	3,245,167
5. Madras General Hospital	—	7,512	52,243
Totals	807	122,686	5,336,365

Administrative Medical Officers: 1. Colonel R. Macrae, I.M.S. 2. Colonel W. G. King, C.I.E., I.M.S. 3. Lieutenant-Colonel G. W. P. Dennys, I.M.S. 4. Colonel R. N. Campbell, I.M.S. 5. The Physicians and Surgeons to the Hospital.

The above figures will give some idea of the work performed for the Indian Government by the officers of the Indian Medical Service. The advantage accruing to the Government of India from such work amongst the natives of the country must be, in truth, incalculable, and the returns of other institutions which have not been sent to us would doubtless bear out the same tale.

Calcutta.

In Calcutta cholera, fevers, small-pox, dysentery, diarrhœa, and plague were less prevalent than in 1907. Especially was this the case with plague.

The case mortality from cholera at the Medical College Hospital deserves especial notice, inasmuch as it was only

36 per cent., as against 51 per cent. in 1907, the diminution being due to the adoption of better methods of treatment. The treatment followed consisted mainly of intravenous injections of large quantities of hypertonic salt solution, as recommended by Major Leonard Rogers, I.M.S.

Malarial fevers gave 43,437 cases (against 44,324 in 1907); dysentery and diarrhœa, 13,833 (against 15,233); plague, 92 (against 300); and small-pox, 258 (against 479). The last-named disease, however, is now raging in a virulent form and causing great mortality. This epidemic was foreseen, and Colonel Macrae, the Inspector-General, has met the emergency with energy.

The death-rate of the cases of enteric fever treated in the Presidency General Hospital was only 9·52 per cent., although many of the patients admitted came from places a considerable distance away, and at a late state of the disease. Beri-beri gave 25 cases with 5 deaths. The number of maternity cases at the Eden Hospital rose from 771 in 1907 to 841 in 1908, and as testifying to the excellence of the arrangements in this hospital it is to be noted that not a single case of septicæmia arose in it during 1907. The surgical operations performed in 1908 amounted to the large number of 33,368 (against 31,848 in 1907).

Most important improvements have been recently completed or are in progress in the Calcutta hospitals. As an example may be mentioned the substitution of gas for the old kerosene-oil lamps in the Campbell Hospital. The present report is the last one that will be submitted by Colonel Macrae as Inspector-General. Under him everything has worked smoothly, and he has made a model chief. He gratefully acknowledges the cordial coöperation he has received from medical officers of all ranks, but we may be allowed to remark that this cordial coöperation is just what would be expected towards so considerate an Inspector-General. There has not, unfortunately, been always so pleasant a relation between the Inspector-General and his junior officers.

Burma.

Colonel W. G. King, C.I.E., in his report for Burma for 1908 makes some very trenchant remarks concerning the poor prospects of the hospital assistants in this province, with the result that no large number of men come forward for entering the service. He clearly states that delay in settling this subject is not a matter that affects the conduct of work to-day; it will, however, mar the efficiency of the department in the near future. The medical department, again, cannot be administered without liberal financial support, and the Inspector-General rightly opines that Imperial aid for a short period by a special yearly grant is as necessary for hospitals in Burma as for sanitation. The sum actually awarded is hopelessly inadequate for the task demanded. This professional opinion is, moreover, corroborated by the Commissioner of the Irrawady Division and by that of an important official visitor. Colonel King seems to have the faculty of at once recognising where improvements are necessary. Such details as the correct equipment for aseptic work, improvement of the nursing staff, better condition of the operation rooms of hospitals, and the desirability of building bacteriological, vaccine, serum, pathological, and parasitological laboratories are all noted by him as absolutely necessary amongst other desiderata, such as electro-therapeutic plants.

Amongst the diseases remarked on, the Inspector-General draws attention to the advisability of organising a sanatorium for tuberculous disease. Especial attention is directed to the subject of yaws, and the services of an expert parasitologist and bacteriologist are shown to be demanded for the investigation of this disease. Beri-beri also earnestly demands investigation. Cases of Malta fever at Makwe and Rangoon were reported by Captain Walker and Captain A. Whitmore, I.M.S. Colonel King concludes his interesting report by according special praise to several medical officers who have worked under him, and also to Miss Sexton, superintendent of the Dufferin Hospital. Such praise is always stimulating.

North-West Frontier Province.

The annual report of the dispensaries of the North-West Frontier Province for the year 1908 is furnished by Lieutenant-Colonel G. W. P. Dennys, I.M.S. A satisfactory increase in the facilities afforded for medical relief in the province is shown, there being an addition of nine new dispensaries during the year, whilst two were closed. There is still room for more to be done. We are glad to see the generous aid afforded by the Nawab of Tonk in giving land for the site of a hospital, and by the Khans of Sam Ranizai similarly near Durgai.

The unhealthiness of the year chiefly contributed to the marked rise of patients, 654,763 out-patients and 10,198 in-patients having been treated, as compared with 565,639 and 10,097 respectively for 1907. There was a large increase in the attendance for cholera, which prevailed as a widespread epidemic in certain parts of the province. Lieutenant-Colonel Dennys draws attention to the difficulty of obtaining the services of men as assistant surgeons, and to the urgent need of improving their prospects. He recommends the creation of a senior grade amongst this class, and is in favour of certain civil surgeoncies being reserved for them. Difficulty has also been found very greatly to exist in the obtaining of qualified compounders on account of the small emoluments received. Lastly, this energetic officer draws attention to the unsatisfactory nursing of indoor patients, and states, as a matter of fact, that nothing exists at present deserving the name of systematic nursing.

(To be continued.)

WOMEN'S NATIONAL HEALTH ASSOCIATION OF IRELAND.

THE third annual meeting of the council of this association was held on April 19th and 20th in the lecture hall, Leinster House, Dublin, under the presidency of Her Excellency the Countess of ABERDEEN.

Annual Report.

The report stated that there were now 168 branches of the association, with a total of 17,543 members, 558 of whom were subscribing members. Over 378,048 leaflets, pamphlets, pictures, posters, and literature of all kinds bearing on health had been printed and distributed during 1909, and 80,500 in addition through the means of the Health Caravan. The Tuberculosis Exhibition Caravan, which was designed to meet the need of outlying places too poor to undertake the expense of a visit from the exhibition, had proved a very successful scheme. It had travelled all round Donegal, and had visited County Armagh, Tyrone, Fermanagh, and the West of Ireland. The funds for maintaining the caravan had been provided by the kindness of the trustees of the Pembroke Irish Charities. The caravan is about to resume its travels through the Counties of Limerick and Kerry. The medical lecturer being unable to take this tour, Miss Fitzgerald, one of their health lecturers, would take her place, and Miss Manderson would give cookery demonstrations and lectures to children. A refreshment van, selling hot and cold pasteurised milk and other nourishing and wholesome food and drinks, had been established by the association in the Phœnix Park during the winter, especially for the benefit of the football players. The first of the disused coastguard stations taken over by the association was opened as a holiday home for preventive cases on August 4th, and since then had received 81 inmates, who had all much improved in health. They came from surroundings where they had been exposed to infection from tuberculosis, but were certified free from the disease themselves before admission. The funds for equipping this home, and maintaining it for five months, were provided by friends at Boston, Mass. The Dublin Pasteurised Milk Depôt, 62, Sitric-road, continued to show most excellent results, as regarded the health of the infants. Most of the infants sent to the depôt were weakly, and were sent there by the medical men because their mothers could not nurse them. Yet it was calculated that the mortality amongst these babies was only 4½ per cent., as against the average Dublin infant mortality of 14½ per cent. Distributing depôts had been started in different quarters of the city.

Dublin Tuberculosis Nurses.

The Dublin Hospitals Tuberculosis Committee was formed in November, 1907, to supervise a scheme of home treatment of consumptive patients by specially qualified Queen's Nurses, under a system of voluntary notification, through the medical staffs of the Dublin hospitals and the Poor-law

dispensaries. It is constituted of medical representatives, one being appointed by each of the ten clinical hospitals in Dublin. Last year the committee was enlarged so as to embrace the Poor-law Medical Service, which sent four representatives. The nurses visit the homes of the patients referred to them, and, aided by the Dublin Women's National Health Association Samaritan Committee, put the sufferers in a position to carry out the medical instructions given to them. The nurses are provided by the Women's National Health Association of Ireland, and when a patient has no medical attendant the association also provides for the supervision of the case by a fully qualified physician. 362 patients were visited by the nurses, and 7275 separate visits were paid. This latter figure represents 140 average weekly visits. 87 patients (or 24 per cent. of the whole number) have shown signs of improvement. 24 patients (being 7 per cent. of the whole, or 27·6 per cent. of those improved) have been able to return to their ordinary work during the year. 100 patients, chiefly through the exertions of the nurses, have been admitted into sanatoriums, hospitals, and kindred institutions. 87 children of parents suffering from tuberculosis have been sent to the country through the Fresh Air Fund. 20 cases which had been exposed to the infection of tuberculosis, but which were certified by their medical man to be free from the disease, were sent to the holiday home, Sutton.

At the evening meeting, at which His Excellency the LORD LIEUTENANT presided, a lecture on

The Need of Medical Inspection in Schools

was delivered by Mr. T. JONES, professor of economics at Queen's University, Belfast. Professor Jones pointed out that the inspection of school premises and the medical examination of school teachers had gone on for some years, but before 1897 there was practically no examination of the school child. Now there were 307 school medical officers in the 328 educational areas into which England and Wales are divided. To these there were to be added 616 assistant medical officers, 122 of whom devoted their whole time to the work of inspection of school children. This medical inspection was showing that the problem of disease and physical unfitness from infancy to the end of school life was one and the same thing, and that the conditions which produced high infantile mortality were exercising injurious influence on the childhood of the State beyond infancy.

The meeting was continued on the following day, when various discussions took place. Amongst the subjects dealt with were Local Tuberculosis Hospitals, Hygiene on Railways, Infantile Mortality, and the Condition of Irish Schools. The Caherdaniel Branch of the association wished to bring forward a resolution concerning the dangers of patients with advanced tuberculosis returning from America, and the resolution was according moved by Miss O'CONNELL in the following terms:—

That the Women's National Health Association of Ireland, being informed that in some districts in Ireland nearly all the cases of consumption originate from infection spread through advanced cases of consumption returning from other countries, desire to approach the Government with a view to taking steps to arrange that the identification of deported cases of consumption from the United States of America, Canada, and other countries should be made direct to the Irish Local Government Board, as well as to the emigration headquarters in London, and that copies of this resolution be forwarded to the Lord Lieutenant, the Chief Secretary, the Irish Local Government Board, and the Emigration Headquarters.

The motion was carried unanimously.

ASYLUM REPORTS.

City of London Asylum, Stone, near Dartford (Report for the Year 1909).—At this asylum the average number of patients daily resident for the year 1909 was 577, as against 570 in 1908. 79 males and 65 females were admitted, making a total of 144. It is interesting to note that among these recovery seemed probable in 26 cases, possible in 46 cases, improbable in 46 cases, and impossible in 27 cases. 109 patients were discharged, and amongst these there were 32 recoveries. The proportion (per cent.) of recoveries to admissions was 29·90 for the two sexes. 31 patients died during the year and 22 necropsies were made. The proportion (per cent.) of deaths to the daily average number resident was 5·37 for the two sexes. The resident physician and superintendent, Dr. R. H. Steen, reports that the new verandahs recently constructed have been of great use in the treatment of patients. The method of treatment by keeping the patients at rest in bed in the open air by day and night is adopted in all fresh cases, and the chief results apparent are diminution in excitement, production of sleep without drugs, and stimulation of appetite.

Ayr District Asylum (Report for the Year 1909).—The admissions for this year numbered 156. The daily average number resident during the year was 536·67, being 13·94 more than last year and 19·67 above the previous record. The number of patients discharged was 79. In the matter of recoveries there is a considerable improvement on last year's figures, being 32·6 per cent. as compared with 22·7 per cent. calculated on the numbers admitted. The number of deaths was 82, or 18·68 per cent. of the average number daily resident. This constitutes a record and has been brought about by a considerable increase among the men, while nearly half of such deaths occurred in those cases which had been resident less than 12 months.

Crichton Royal Institution, Dumfries (Report for the Year 1909).—The average daily number resident at this institution was 845. Voluntary boarders numbered 60, this being the highest number hitherto reached in the course of a year. There were 160 admissions, representing 157 persons, three men having been admitted twice in the year. The mean age of the patients on reception was 45 years. Three fifths belonged to the middle period of life, between 30 and 60 years, one-fifth were below 30, and one-fifth above 60. There were 121 discharges during the year, representing 119 persons, of whom 92 were certificated and 27 were voluntary boarders. 18 of the voluntary boarders were restored to health and the others, with the exception of 2, were much improved. Of the 92 certificated patients, 56 left recovered, and the recovery rate, based on the receptions, was 50 per cent. The forms of mental affection recovered from were chiefly melancholia and mania, and in 70 per cent. of the recoveries the mental illness had lasted in all less than a year. During the year 66 certified patients and 1 voluntary boarder died. The mortality rate among certified patients, based on the average resident population, was 8·1 per cent. Necropsies were performed in 75 per cent. of the deaths. Dr. C. C. Easterbrook, the physician superintendent, reports the establishment of three Crichton Fellowships in clinical neurology and psychology, in pathology and bacteriology, and in pathology and chemistry, having reference to the nervous system. These Fellowships are of the value of £250 a year each, with board, quarters, attendance, and laundry, or an allowance of £50 a year in lieu of these. It is satisfactory to note that the valuable material contained in our British mental hospitals and asylums is being increasingly made use of, especially where, as in this case, the managing bodies of such institutions have in an enlightened spirit sought to establish efficient laboratories controlled by properly qualified persons.

Kingseat Asylum, Aberdeen (Report for the Year 1909).—At this asylum the total number under treatment was 14 in excess of last year, the average daily number being 434. The admissions numbered 118. General paralysis again showed an increase. Dr. H. de Maine Alexander, the medical superintendent, points out that this disease is liable to be overlooked in its prodromal stage on account of the absence of the typical mental symptoms supposed to be usually associated with the disease, though in fact these mental symptoms are more often absent than present, the abnormal physical signs alone pointing to the disease. The discharges numbered 54, while the percentage of recoveries on the admissions was 27·9. We are happy to notice that a beginning has been made in boarding out patients in the vicinity of the asylum, the patients being visited at intervals by Dr. Alexander himself. The patients are well cared for, treated as ordinary members of the household, attend church with their guardians, and from time to time visit the asylum for entertainments. Deaths in the asylum numbered 27 during the year, the figure giving a death-rate of 6·2 per cent. on the average number resident.

Barnwood House Hospital for the Insane, near Gloucester (Report for the Year 1909).—At this hospital the average number daily resident was 148, of whom 58 were males and 90 females. 35 patients were admitted and of these six were transfers. 27 patients were discharged and of these 14 were discharged recovered, this being a percentage of 40 per cent.

calculated upon the total admissions. The number of deaths was 5, the death-rate being 3·37 per cent. calculated upon the daily average number resident. Concerning the statistical tables appended to the report Dr. J. G. Soutar very wisely points out that it cannot be pretended that the whole truth is told in any given case. "As it is beyond the power of the biographer to fully ascertain, or to analyse, or to truly estimate the conditions, the circumstances, the influences which operate through progenitors and directly on the individual, to build up in his subject a vigorous mind and strong character, so he who carefully inquires into the causes of mental defect and failure finds himself baffled by the multitude and the subtlety of the factors involved." The study which the compilation of the tables necessitates does, however, assist the physician in enabling him to prescribe the proper *régime* for a patient on recovery.

BRITISH MEDICAL BENEVOLENT FUND.

AT the April meeting of the committee 27 cases were considered and grants amounting to £251 made to 24 of the applicants. Appended is an abstract of the cases assisted:—

Daughter, aged 63 years, of late M.R.C.S. Has a small weekly allowance from a medical provident society. Mental condition such that, whilst unsuitable for an asylum, a certain amount of supervision is necessary and the cost of living consequently increased. Relieved 11 times, £108. Voted £12.

Widow, aged 51 years, of L.R.C.P., L.R.C.S. Edin. Has a little Irish property, but rent is greatly in arrears. Three children, but none able to help and one in ill-health. Relieved twice, £12. Voted £12.

M.R.C.S., aged 64 years. Lost a considerable amount in a practice which did not turn out as represented, and is now in feeble health, which prevents anything but light and occasional work. Two sons, aged 21 and 19 years, who give as much help as possible. Relieved twice, £20. Voted £10.

Widow, aged 88 years, of M.R.C.S. Receives an old-age pension and 5s. per week from a benevolent society. No children; practically bedridden. Voted £6.

Widow, aged 38 years, of L.R.C.P., L.R.C.S. Edin. Endeavours to maintain herself by nursing, which necessitates boarding out her two children. Relieved four times, £30. Voted £10.

Widow, aged 58 years, of L.R.C.P., L.R.C.S. Irel. After husband's death took a post as housekeeper, but health has quite broken down and she is now practically destitute. No children. Relieved twice, £10. Voted £18.

Widow, aged 61 years, of L.R.C.P. Edin. Has supported herself for many years by taking boarders, but finds them increasingly difficult to obtain. Three children, one of whom has just developed phthisis. Relieved four times, £48. Voted £12.

Widow, aged 45 years, of M.R.C.S., L.R.C.P. Has a small annuity, but asks for assistance towards school fees of her two children, aged 16 and 13 years. Health very indifferent. Relieved six times, £85. Voted £5.

Widow, aged 62 years, of L.R.C.P. Edin. Health too delicate to undertake any occupation, and is entirely dependent on a brother-in-law. No children. Relieved once, £12. Voted £12.

Daughter, aged 35 years, of late M.D. Glasg. Has maintained herself by massage for several years, but is at present incapacitated owing to the results of rheumatic fever. Relieved once, £10. Voted £10.

Widow, aged 62 years, of L.R.C.P. Edin. No income and is quite incapacitated by an incurable complaint. Occasional slight help from a son. Relieved four times, £48. Voted £12.

M.R.C.S., aged 71 years. Quite incapacitated and dependent on children, who make a small monthly allowance. Relieved once, £12. Voted £2, and to be advised to apply for an old-age pension.

Widow, aged 49 years, of M.R.C.S. No income, endeavours to support herself by needlework. Health indifferent and eyesight failing. Children unable to help. Relieved eight times, £83. Voted £12.

Widow, aged 60 years, of L.S.A. Lets lodgings, but finds difficulty in paying her rent. Slight help from children. Relieved eight times, £90. Voted £10.

Daughter, aged 63 years, of M.D. Lond., M.R.C.P. Has recently been elected to a small annuity, but the income is insufficient for the bare necessities of life. Relieved three times, £27. Voted £5.

Daughter, aged 60 years, of late M.D. Edin. Has given music lessons for many years, but finds increasing difficulty in obtaining pupils. Relieved three times, £30. Voted £10.

Widow, aged 69 years, of M.D. Aberd. Only income a small monthly allowance made by a friend. Children unable to help. Relieved nine times, £114. Voted £10.

Daughter, aged 64 years, of late F.R.C.S. Only income £10 a year from a Society for the Relief of the Blind. Is in bad health and almost destitute. Relieved five times, £42. Voted £12.

Widow, aged 58 years, of L.R.C.P. Edin. No income; lets lodgings, but had a very bad season last year and the receipts are barely sufficient for rent and rates. Relieved seven times, £82. Voted £12

Widow, aged 61 years, of M.R.C.S. Lets lodgings, but has had some of her rooms vacant for some time. Six children, but only one able to help and one a chronic invalid. Relieved four times, £52. Voted £18.

Widow, aged 47 years, of L.R.C.P., L.R.C.S Edin. No income; two sons, both sailors, but only one able to give slight help. Relieved six times, £32. Voted £12.

Daughter, aged 60 years, of late M.R.C.S. Acts as housekeeper to her brother but receives no salary. Relieved eight times, £120. Voted £12.

Daughter, aged 55 years, of late L.F.P.S. Glasg. Receives £10 a year from a fund for assisting indigent gentlewomen and lives rent free. Health too feeble to allow of any occupation. Relieved three times, £36. Voted £12.

Daughter, aged 26 years, of late M.R.C.S. Has taken out a course of cookery and hopes shortly to be able to maintain herself. Relieved three times, £17. Voted £5.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 3rd, 1851.

Extract from a leading article in reference to Mr. Propert's proposal to found a Medical College at Epsom.

We highly approve of the plan of supporting a number of medical pensioners, but we give our special support to the collegiate department of the proposed institution. ..... At the Marlborough College, exhibitions and scholarships have been founded, and are still in process of formation, with a view of sending the most distinguished scholars to Oxford and Cambridge, to complete their education, and to struggle for the great prizes which those venerable seats of learning offer. Already some of the highest honours in the Universities have been carried off by the *élèves* of this recently established school.

We should be delighted at such a prospect for our medical youth. The old physicians were amongst the most munificent donors to the Universities; yet by some misarrangement the children of the profession seem quite separated from these repositories of wealth and lore. The proposed college ought to supply an excellent education to all, and in this way it would be an inestimable boon to the profession, but to distinguished scholars it ought to give the means of proceeding to the universities and wresting away some of that fame and emolument which now almost seem the prescriptive rights of the other professions. We are persuaded that, with fair play, the intellect of the medical youth of this country would win triumphs conferring lustre on the entire profession.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns 8476 births and 4258 deaths were registered during the week ending May 7th. The annual rate of mortality in these towns, which had been equal to 15·0, 13·7, and 13·1 per 1000 in the three preceding weeks, was again so low as 13·1 in the week under notice. During the first five weeks of the current quarter the annual death-rate in these towns averaged 14·0 per 1000, and in London during the same period the rate did not exceed 13·6 per 1000. The lowest recorded annual rates of mortality during last week in these 77 towns were 5·8 in Hornsey, 6·3 in Willesden and in Tottenham, and 6·6 in Leyton, all being suburban Metropolitan districts; the rates in the other towns ranged upwards, however, to 19·4 in Great Yarmouth, 19·9 in Oldham, 21·6 in Merthyr Tydfil, and 22·3 in Stockton. In London the recorded death-rate last week did not exceed 12·5 per 1000. The 4258 deaths registered last week in the 77 towns showed an increase of but 9 on the low number returned in the previous week, and included 386 which were referred to the principal epidemic diseases, against 345 and 364 in the two preceding weeks; of these 386 deaths, 160 resulted from whooping-cough, 116 from measles, 44 from diarrhœa, 30 from diphtheria, 24 from scarlet fever, and 12 from enteric fever, but not one from small-pox. The mean annual rate of mortality in the 77 towns last week from these epidemic diseases was equal to 1·2 per 1000, against 1·1 in each of the two preceding weeks. No death from any of these epidemic diseases was registered last week in Bristol, Willesden, Brighton, Derby, Southampton, or in 10 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2·8 in Manchester, 3·0 in Bootle, 3·3 in Merthyr Tydfil, and 3·5 in South Shields. The fatal cases of whooping-cough in the 77 towns, which had been 143 and 138 in the two preceding weeks, rose to 160 last week; they caused annual death-rates equal to 1·4 per 1000 in Bolton, 1·5 in Salford, 1·6 in Rotherham, and 2·2 in South Shields. The 116 deaths from measles slightly further exceeded the numbers in the two previous weeks; the highest death-rates from this disease during the week were 1·6 in Croydon, 1·7 in East Ham, 1·9 in Burton-on-Trent, and 2·0 in Merthyr Tydfil. The 44 deaths attributed to diarrhœa also showed an increase

upon recent weekly numbers. The 30 deaths referred to diphtheria were, however, 10 below the number in the previous week; they included 3 in Manchester, 3 in Birmingham and King's Norton, and 2 in Bournemouth. The fatal cases of scarlet fever, which had been 27 and 20 in the two preceding weeks, rose again last week to 24, of which 8 occurred in London and its suburban districts, 4 in Liverpool, and 3 in Manchester and Salford. The 12 deaths referred to enteric fever included 3 in Liverpool and 2 in Nottingham. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily declined in the 29 preceding weeks from 2810 to 1509, further fell to 1506 during last week; 179 new cases of this disease were admitted to these hospitals during last week, against 196 and 192 in the two preceding weeks. Of the 1167 deaths registered in London during the week under notice 211 were referred to pneumonia and other diseases of the respiratory system, showing a further decline from the numbers returned in recent weeks; these 211 deaths were 63 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 40, or 0·9 per cent., of the deaths registered in the 77 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during the week were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, and in 52 other smaller towns; the 40 uncertified causes of death in the 77 towns last week included 7 in Liverpool, 5 in Birmingham, 4 in Hull, and 3 both in Manchester and in Barrow-in-Furness.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 980 births and 564 deaths were registered during the week ending May 7th. The annual rate of mortality in these towns, which had been equal to 16·3 and 17·4 per 1000 in the two preceding weeks, declined to 15·6 in the week under notice. During the first five weeks of the current quarter the death-rate in these towns averaged 17·2 per 1000, and exceeded by 3·2 the mean rate during the same period in the 77 largest English towns. The annual death-rates last week in these eight Scotch towns ranged from 9·0 and 11·8 in Leith and Aberdeen, to 17·7 in Greenock and 28·8 in Dundee. The 564 deaths from all causes in the eight towns during last week showed a decline of 66 from the number in the previous week, and included 87 which were referred to the principal epidemic diseases, against numbers declining from 123 to 76 in the four preceding weeks. These 87 deaths were equal to an annual rate of 2·4 per 1000; the mean death-rate from the same diseases in the 77 English towns last week did not exceed 1·2 per 1000. These 87 deaths in the Scotch towns last week included 52 from measles, 12 from diarrhœa, 11 from whooping-cough, 7 from scarlet fever, 4 from diphtheria, and 1 from "fever," but not one from small-pox. The fatal cases of measles in the eight towns, which had in the four preceding weeks declined from 74 to 44, rose again last week to 52, and included 26 in Dundee, 13 in Glasgow, 7 in Edinburgh, and 5 in Greenock. The 12 deaths attributed to diarrhœa showed a decline from the numbers in recent weeks; 5 were returned in Glasgow, 3 in Dundee, and 2 both in Edinburgh and in Perth. The fatal cases of whooping-cough, which had been 6 and 7 in the two previous weeks, rose to 11 last week, of which 7 occurred in Glasgow. Five of the 7 deaths from scarlet fever were registered in Glasgow; and of the 4 fatal cases of diphtheria 2 occurred in Paisley. Only one death during the week was referred to "fever"; it was recorded in Greenock. The deaths in the eight towns referred to diseases of the respiratory system, which had been 92 and 93 in the two preceding weeks, declined last week to 77, and were 11 below the number in the corresponding week of last year. The causes of 13, or 2·3 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 629 births and 443 deaths were registered during the week ending May 7th. The mean annual rate of mortality in these towns, which had been equal to 23·2, 22·4, and 22·0 per 1000 in the three preceding weeks, further declined to 20·1 in the week under notice. During the first five weeks of the current quarter the annual death-rate in these Irish towns averaged 22·2 per 1000, whereas the mean rate during the same period did not exceed 14·0 in the 77 largest English towns, and 17·2 in the eight principal Scotch towns. The annual death-rate during last week was equal to 16·7 in Dublin, 22·3 in Belfast, 25·3 in Cork, 18·0 in Londonderry, 12·3 in Limerick, and 29·2 in Waterford; the mean annual death-rate last week in the 16 smallest of these Irish town districts was equal to 22·0 per 1000. The 443 deaths from all causes in the 22 town districts last week showed a further decline of 42 from the numbers in recent weeks, and included 43 which were referred to the principal epidemic diseases, against 41 and 39 in the two preceding weeks; these 43 deaths were equal to an annual rate of 1·9 per 1000; in the 77 English towns the mean rate last week from the same diseases did not exceed 1·2 per 1000, while in the eight Scotch towns it was equal to 2·4. The 43 deaths from these diseases in the Irish towns last week included 20 from measles, 14 from whooping-cough, 5 from "fever," 3 from diarrhœa, and 1 from diphtheria, but not one either from small-pox or scarlet fever. The 20 fatal cases of measles in the 22 towns corresponded with the number in the previous week and included 19 in Belfast. The 14 deaths from whooping-cough exceeded the number in the previous week by 2; 6 occurred in Drogheda, 4 in Belfast, and 2 in Limerick. Two of the 3 deaths from diarrhœa were registered in Belfast. The 4 deaths referred to enteric fever included one each in Dublin, Cork, Waterford, and Queenstown. The deaths in the 22 towns referred to pneumonia and other diseases of the respiratory system, which had declined in the four preceding weeks from 129 to 96, further fell last week to 93. The causes of 14, or 3·2 per cent., of the deaths registered in the 77 English Irish towns last week were not certified; of death last towns the proportion of uncertified causes eight principal week did not exceed 0·9 per cent., and in the Scotch towns it was equal to 2·3 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon Lawrence Bidwell has been placed on the Retired List at his own request (dated May 2nd, 1910).

The following appointments are notified:—Staff-Surgeons: O. Mills to the *Vivid*, additional, to be lent to Plymouth Hospital; W. P. Walker to Plymouth Hospital.

The undermentioned Surgeons have been promoted to the rank of Staff-Surgeon in His Majesty's Fleet:—Leonard Sykes Whitwam (dated Feb. 26th, 1910), John George Peebles, Elijah Richard Lockwood Thomas (dated Feb. 8th, 1910).

In accordance with the provisions of the Order in Council of April 1st, 1881, Fleet-Surgeon Edward Pain Mourilyan has been placed on the Retired List, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets (dated April 25th, 1910).

ARMY MEDICAL SERVICE.

Major Bertal H. Scott, R.A.M.C., to be a Deputy Assistant Director-General at the War Office, vice Major H. J. M. Buist, D.S.O., whose tenure of that appointment has expired (dated May 1st, 1910).

ROYAL ARMY MEDICAL CORPS.

Major Charles H. Hopkins is placed temporarily on the Half-pay List on account of ill-health (dated April 30th, 1910).

Lieutenant-Colonel S. C. Philson, from the London District, has, on arrival in India, been appointed to command the station hospital at Delhi, vice Lieutenant-Colonel W. E. Berryman. Lieutenant-Colonel S. Powell has been transferred from Maymyo to Rangoon. Lieutenant-Colonel H. Carr, from the Royal Victoria Hospital, Netley, has

appointed to command the station hospital at Jullundur. Major W. C. Poole, from Buttevant, has joined for duty at Rawalpindi. Major J. W. Bullen, from Madras, has been appointed to command the station hospital at Wellington Sanatorium. Major B. J. Inniss from Meerut has been posted to Gravesend. Major F. J. Wade-Brown has taken up duty in the Cork District. Major W. D. Erskine has been transferred from Strensall to York. Major C. Dalton has been appointed Staff Officer to the Principal Medical Officer of the Irish Command. Major C. W. Profeit, from the Military Hospital, Bulford Camp, Salisbury Plain, has been appointed to Rochester Row Military Hospital, London, S.W. Captain R. T. Collins has been transferred from Chakrata to Meerut. Captain R. J. Cahill, on completion of a course of instruction at the X Ray Institute at Dehra Dun, has been posted to Bangalore. Captain J. D. Richmond, from Quetta, has joined Cork District. Captain F. Forrest, from Ambala, has been posted to Kasauli. Captain D. de C. O'Grady has been transferred from Nowshera to Rawalpindi. Captain J. H. Douglas and Captain M. Sinclair, on return from a tour of foreign service in India, have been posted to the Irish Command. Captain L. M. Purser, from Colchester, has been appointed a Specialist in Otology and Rhinology to the Second (Rawalpindi) Division. Lieutenant G. H. Stack, from Aldershot, has embarked for a tour of service on the West Coast of Africa. Lieutenant T. H. Scott and Lieutenant A. G. Wells have been transferred from Lahore Cantonment to Ferozepore for duty at the station hospital. Lieutenant C. H. O'Rorke, from Birr, has been posted to the Curragh. Lieutenant A. W. Byrne has been transferred from Lancaster to Manchester. Lieutenant W. E. C. Lunn has been appointed staff surgeon at Lahore Cantonment.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel T. W. Stewart, on return from leave, has been appointed to the civil medical charge of the Akyab District, vice Major J. Penny, proceeding on leave. Lieutenant-Colonel C. C. Manifold has been promoted Colonel. Lieutenant-Colonel J. T. Daly has been granted one year's furlough. Major H. Ainsworth has been appointed Professor of Ophthalmic Surgery at the Medical College, Lahore. Major W. Selby, Civil Surgeon at Azamgarh, has been appointed an Honorary Surgeon to H.E. the Viceroy of India and transferred to Gorakhpur, vice Major C. Milne, granted leave. Major J. M. Crawford, Civil Surgeon at Benares, has been granted privilege leave combined with furlough for six months. Major E. R. Parry, superintendent of the Central Jail at Dacca, has been granted eight months' combined leave. Major T. Jackson has arrived home. Major B. Oldham, Civil Surgeon at Patna, has been appointed to the medical charge of the 24th Pergunnas at Alipore, vice Major F. O'Kinealy. Major J. H. McDonald, on return from leave, has been appointed to officiate as Civil Surgeon at Belgaum, vice Major H. Bennett. Captain I. M. Macrae has been appointed to officiate as Superintendent of the Central Prison at Lucknow, vice Major C. B. Prall. Captain L. E. Gilbert, Civil Surgeon, Traunggyi, has been granted two years' leave. Captain R. D. Saigol has been posted to Meikhta as Civil Surgeon, vice Captain E. A. Walker, transferred to Bassein to relieve Major P. Dee, who has proceeded on leave. The services of Captain J. Husband have been placed at the disposal of the Government of Burma.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Duncan Macfadyen to be Lieutenant (on probation) (dated Feb. 26th, 1910).

TERRITORIAL FORCE.

Royal Army Medical Corps.

Welsh Border Mounted Brigade Field Ambulance: Lieutenant William Smith, from the Eastern Mounted Brigade Field Ambulance, Royal Army Medical Corps, to be Lieutenant (dated March 1st, 1910).

1st East Lancashire Field Ambulance: Joseph Marshall Postlethwaite to be Lieutenant (dated Feb. 2nd, 1910). Lieutenant Cecil W. Hutt resigns his commission (dated March 31st, 1910).

3rd East Lancashire Field Ambulance: Henry Herbert Rayner to be Lieutenant (dated Feb. 3rd, 1910).

1st Southern General Hospital: Major Robert M. Simon to be Lieutenant-Colonel (dated August 5th, 1909). Captain James W. Russell to be Major (dated August 5th, 1909).

THE COURSE OF INSTRUCTION AT HASLAR.

The course of instruction of the newly entered Surgeons at Haslar was brought to a close on April 7th by the distribution of the prizes by Inspector-General James Porter, C.B., K.H.P., Director-General of the Medical Department of the Royal Navy. The gold medal was gained by Surgeon R. J. G. Parnell (King's College Hospital), and the silver medal was awarded to Surgeon J. H. B. Martin (University of Cambridge and London Hospital). These two officers took the first and second places respectively in the combined London and Haslar examinations. Three Navy Regulation pocket cases—prizes for subjects in which instruction is given at Haslar—were awarded to Surgeons R. J. G. Parnell, J. H. B. Martin, and T. C. Patterson. The following list shows the places gained by the combined marks of the London and Haslar examinations:—

	Marks.		Marks.
R. J. G. Parnell	5037	F. C. Searle	4434
J. H. B. Martin	4690	A. G. V. French	4374
F. L. Smith	4620	W. E. Lloyd	4322
C. D. Bell	4585	J. P. Barry	4201
T. C. Patterson	4552	C. G. Sprague	4044
M. H. Langford	4526	A. C. Rusack	3980
A. Fairley	4489		

ROYAL ARMY MEDICAL CORPS EXAMINATIONS.

An examination of candidates for not less than ten commissions in the Royal Army Medical Corps will be held on July 27th and following days. Applications to compete should be made to the Secretary, War Office, London, not later than July 18th, on which date the list will be closed. The presence of candidates will be required in London from July 25th.

AN OFFICERS' TRAINING CORPS IN DUBLIN.

The opportunity which has recently been opened to the students of Trinity College and those of the Royal College of Surgeons in Ireland of undergoing a course of voluntary training for military service has been extensively utilised. It was well known that the idea would be popular with Irish students, and proof has been furnished by the fact that within a few weeks of the inception of the movement some 200 names of students have been enrolled at Trinity College, and about 70 at the Royal College of Surgeons. The organisation is, inevitably, not quite complete at present, and stores and equipments of various kinds have still to be provided; but the cadets, as the members are called, have already commenced the performance of the preliminary drills. Dr. A. C. Geddes, Acting Professor of Anatomy at the Royal College of Surgeons, who has taken an enthusiastic part in the organisation of the Officers' Training Corps, served with the army in the Boer war, and contradicts the view that such systematic military training is a waste of time of even the medical student preparing for examinations, as he calculates that not more than an average of two hours per week will be spent in the training.

A recent Admiralty circular states that "It is contemplated that the 'command' of all officers of branches, other than the military branch, over their subordinates in their own departments shall be as definite as that of officers of the military branch." Unless this is mere temporising the power of Inspectors-General over the staff of naval hospitals should, therefore, soon be clearly defined.

MEDICAL MISSIONS.—The Medical Mission Auxiliary of the Church Missionary Society held its annual meeting in the Queen's Hall, London, on May 6th, Mr. A. Carless being in the chair. The annnal report was read by the Rev. R. Elliott, L.R.C.S.Irel., secretary to the Medical Committee, and showed that the society now maintains 50 hospitals in various parts of the world, with a total of 3075 beds in which over 29,000 patients were treated last year, besides which over 1,100,000 visits of out-patients were recorded. The chairman drew attention to the magnitude of this work, to the economical administration—the expenditure being less than £40,000—and to the high qualifications of the men engaged in it; one of the missionaries present on the platform (Dr. T. L. Pennell) was a gold medallist, and all were men who would have been in the front rank of the profession at home. The meeting was also addressed by Dr. B. van Someren Taylor, of Hing-hwa, China; Dr. Pennell, of Bannu, on the north-west frontier of India; and Mr. J. H. Cook, of Mengo, Uganda, who gave some account of their work as medical missionaries.

THE HOSPITAL INFECTION OF TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—The paper read on April 26th at the Royal Society of Medicine by Dr. J. E. Squire, as reported in your issue of last week, gave rise to a most interesting discussion. There was obviously not sufficient time to deal fully with all the points at issue. Owing to the short time left for discussion and the fact that the audience was composed of such distinguished physicians who evidently wished to speak, I felt diffident about taking up the time of the meeting with any remarks of my own. One point, however, seems to me of such great importance that I feel justified in asking you to allow me to refer to it in your columns. Dr. Squire's figures with regard to the number of people affected by tubercle during and after residence at the Mount Vernon Hospitals showed a higher percentage than those previously published by other observers. It was claimed that this was the result of very strict personal observation and medical examination, but Dr. Squire admitted that he had accepted for service at the hospitals persons who showed evidence of having had previous tuberculosis in a slight degree. No less eminent physicians than Dr. Theodore Williams, Dr. G. A. Heron, and Dr. Nathan Raw said they thought it unwise that persons who presented *any* evidence of having had previous tuberculosis should be accepted for posts in hospitals or sanatoria for the treatment of that disease.

Now, Sir, each of these gentlemen had previously stated that he believed the risk of infection in a well-ordered institution to be practically *nil*. Why, then, should a person with evidence of old mischief be excluded? This declaration from Dr. Nathan Raw caused me great surprise. If I have read his work correctly, a person who has had what he considers to be bovine infection is rendered to a certain extent immune against infection of the human type. This being so, it does seem illogical for him to say that a person with any evidence of old tuberculosis should not be allowed to join the staff of an institution where the risk is practically *nil*, where the utmost care is taken to prevent any carelessness, and where the hygienic conditions are as perfect as anywhere in the community.

A medical man finds himself affected with tubercle; he is told by such experts as Dr. Williams, Dr. Heron, and Dr. Raw that the risk in a well-ordered tuberculosis hospital is practically *nil*, what is more natural and reasonable than that he should apply for a post in one? Yet these same gentlemen would exclude him. Dr. Heron pointed out that "the homes of the poor were a much more likely source of infection," so presumably the affected individual must not enter general practice. Dr. Wethered believes with Dr. Squire that the risk in a general hospital is greater than in the tuberculosis hospital. Where, then, is the unfortunate man to go? I can only think of the lethal chamber.

Suppose a person presented himself to any of these gentlemen as a patient, and he was found to have early tuberculosis, he would doubtless be sent to a sanatorium for treatment, and advised to make a lengthy stay. If that environment is suitable for him, why is it so unsuitable for a resident physician who is, or has been, affected similarly? The patient would spend all his time amongst other cases presenting more or less activity; the physician with his quiescent or arrested focus only a comparatively short time.

I am acquainted with many medical men who have taken up this work because of previous infection. If a personal reference may be allowed, I am unfortunately one of the number. I have never heard of one who regretted the step, and my own experience has been exceedingly gratifying. For many years before coming to Northwood I had been fighting an uphill battle against this foe, but acting upon the advice of Dr. T. N. Kelynack, one of the honorary physicians of this institution, I applied for a post here, obtained it, and for five and a half years have had increasingly good health. Personally, I feel greatly indebted to Dr. Squire, who instead of being guided by the theories of others, has taken his own line and admitted for service those in whom there was evidence of old mischief, thus providing others and myself not only with the opportunity to do useful work, but to keep a measure of health hitherto not experienced.

I feel sure that many of your readers can give similar experience to my own.—I am, Sir, yours faithfully,

W. G. KINTON,
Medical Superintendent, Mount Vernon Hospital, Northwood.

May 9th, 1910.

A PROLONGED NASAL GAS ADMINISTRATION.

To the Editor of THE LANCET.

SIR,—As the longest case of continuous nasal administration of nitrous oxide gas I can find recorded is one of 17 minutes, I hope I may be pardoned for sending you an account of a case I have just had at the Royal Dental Hospital, London. The patient, a man, 22 years of age, came up for a dental operation on the lower jaw which proved to require more time than was expected. He was seated in a dental chair in the ordinary manner and no unusual precautions were taken. Anæsthesia was induced by the oro-nasal method and was continued by a nose-piece fitted with a valve, no oxygen (apart, of course, from that in the air) being used. The operation lasted 37 minutes and close on 100 gallons of gas were used. The patient's pulse at the wrist the instant the administration was stopped was very small and rather rapid. I regret I did not count it by the watch, but I should think it was about 90. He took rather longer to come round than usual and trembled a little. He was laid on a couch and covered with a blanket, but rapidly recovered and was soon sitting up rinsing his mouth as if he had only had a short administration, and left the hospital in the usual way in about 15 to 20 minutes. The next day he returned to have his mouth dressed and said he had had neither headache nor nausea, and, in fact, seemed to have suffered in no way from his somewhat prolonged anæsthesia.

I am, Sir, yours faithfully,

CHARLES J. LOOSELY, L.R.C.P. Lond., M.R.C.S. Eng.

New Cavendish-street, W., May 9th, 1910.

PATHOLOGICAL LATIN.

To the Editor of THE LANCET.

SIR,—One often feels regret that Latin is no longer the accepted literary medium of learned men, and nothing but admiration can be felt for the praiseworthy endeavours made in the Transactions of the Pathological Section of the Royal Society of Medicine to revive this custom. It is, however, permissible to doubt whether those foreigners who *ex hypothesi* know Latin better than English would not appreciate classical Latin as much as the dialect now employed for their benefit in this publication—whether, indeed, they might not erroneously attribute some of the peculiarities of diction found therein to ignorance of Latin grammar rather than, as no doubt they should, to a preference for some mediæval idiom. In the current number of the Transactions, for example, we find a peculiar and quite unclassical use of the preposition "cum" (together with) several times repeated—e.g., "tumoris exemplum *cum* degeneratione amyloide affecti," "cellulis magnis *cum* oleo distentis," "spherulae *cum* biliverdino tinctae"—a form of construction for which at school we should scarcely have escaped rebuke. Might we not also appeal to the learned author, for the sake of those who may, like the present writer, have but distant recollections of classical speech, to aim at rather greater simplicity of style than he always adopts? As an example of involved construction the sentence, "E lobulis constat illis vix dissimilibus hepatis ipsius" seems (if a colloquialism may be Latinised for the foreigner's benefit) "placentam capere"; while the meaning of the sentence, "Inter cellulas, autem, monstrantur ductus qui canaliculi biliares forsan repraesentant" is quite obscure, unless it is to be supposed that the printer maliciously substituted the nominative "canaliculi" for the accusative "canaliculos." Conscious of my temerity in venturing upon the above criticism, and apologising for the length of this letter,

I am, Sir, yours faithfully,

May 9th, 1910. ORBILII DISCIPULUS.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Bristol Orthopædic Hospital.

THE thirty-third annual meeting of the supporters of the Orthopædic Hospital, Bristol, was held on April 26th at the institution, when Mr. William Garnett presided. The financial statement showed an income for 1909 of £1803 11*s.* 1*d.*, leaving an adverse balance of about £10. The sum realised by regular subscribers was only £193, a very unsatisfactory total in view of the usefulness of the work done by the hospital.

Bristol School of Industry for the Blind.

At the annual meeting of the friends of this institution held on April 25th, it was stated that the new premises now being erected on the outskirts of the city would probably be ready for occupation by the end of the year. The building at present in use has been purchased by the University, the newest additions to which stand on ground belonging to the blind school. The number of children at present being educated by the school is 99, and there are 74 adults employed in the workshops. In addition to these there are about 300 blind persons in the city under the supervision of visiting teachers, and 30 ex-pupils, under the care of sponsors, living at a distance from Bristol. It is to the city's credit that an income of £5090 is forthcoming, only £345 of which comes from the Board of Education.

Bristol Royal Hospital for Sick Children and Women.

The annual meeting of the "Ladies Auxiliary" in connexion with this institution was held on April 27th, under the presidency of the Duchess of Beaufort. The report showed that during 1909 the sum of £818 had been collected. It was stated that the late Miss Lawrence had bequeathed £500 to endow a cot in the hospital, this sum of money having been left to the Ladies Auxiliary for that purpose.

Royal Devon and Exeter Hospital.

The Exeter Amateur Operatic Society recently gave some performances of the *Yeoman of the Guard*, which, after paying necessary expenses, resulted in a sum of about £130 being raised. The committee of the society has given £100 to the Royal Devon and Exeter Hospital and £25 to the Devonshire Nursing Association. During the past four years the Exeter Amateur Operatic Society has raised £445 for the local medical charities.

The Devonshire Education Committee.

At the last meeting of the Devonshire education committee it was reported that a nurse who had been temporarily appointed in connexion with the inspection of children suffering from pediculi had received some intimidating letters, and had been forced to carry out her duties under police protection.

Pediculosis at Exeter.

At the Exeter police-court on April 28th the Exeter education authority summoned five parents for allowing their children to become infected with vermin after they had been cleansed. It was stated that the medical inspection of school children showed that several were suffering from pediculosis and that the local authority had established a cleansing station for the children and their clothing. The medical inspector and nurse had done all they could to make the parents carry out the provisions of the Education Act. The bench of magistrates were pleased that the local authorities realised their responsibilities, and added "that the law provided free education, a doctor, and the assistance of a nurse, and all the parents had to do was to find the soap and water." One of the parents, an invalid, was fined 1*s.*, and the others 2*s.* 6*d.*

The Gloucestershire Education Committee.

At the last meeting of the Gloucestershire education committee it was decided to appoint Miss Mary Deborah Hancock, L.R.C.P. & S. Edin., L.F.P.S. Glasg., as lady medical inspector at a salary of £250 per annum. It was reported that the medical inspection of school children cost at present £1700 a year, but it would probably be larger in the future.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Educational Treatment of Consumptives.

THE city council has approved the scheme of the health committee to make certain additions and alterations to the emergency hospital to fit it for the temporary educational treatment of consumptives. Alderman Fletcher, in presenting the report, said that the efforts towards reducing the number of cases of consumption had turned out to be one of the hardest tasks they had undertaken. Deaths from phthisis had in the past ten years averaged 750 to 800 a year—a far larger number than that of deaths due to all the other infectious diseases combined. At the Salterley Grange Sanatorium they aimed at selecting patients in the early stages of the disease and, as far as was humanly possible, effecting complete cures. Their experience at Salterley Grange had taught them several things. They found that the majority of cases examined had passed beyond the early stage before the patients realised it, and 90 per cent. had to be rejected as unsuitable. But the majority of those unsuitable for Salterley Grange could be greatly benefited by a course of such treatment as was proposed to be pursued at the emergency hospital. In some cases cures might be effected, many lives would be prolonged, and all would learn from experience the value of open-air treatment and careful regulation of their lives. They would be taught to help themselves in many ways and to guard others from infection when they returned home. With regard to the medical staff, they proposed to have a junior medical man in residence, and he would be under the superintendence of the medical officer of health; they also proposed making arrangements for the help of a local physician skilled in treatment of phthisis. No sinking fund was provided for in the scheme, consequently the cost of maintenance would be reduced, and he thought it would be demonstrated that this was the cheapest sanatorium for consumptives to be found. Councillor Dr. A. H. Carter, in seconding, referred to the amount of wages that were lost through consumption. During 1909 there were 757 deaths. One of the largest friendly societies calculated that on the average they had to pay out 58 weeks' out-of-work pay to every patient that died. It was also calculated that amongst the fatal cases from consumption 82 per cent. occurred amongst wage-earning adults. Assuming the average wage to be 10*s.* a week, that represented nearly £18,000 lost in wages to Birmingham. He considered that £2500 annual expenditure was not much compared with the saving of a large proportion of the amount lost in wages, which was only one of the many losses that could be pointed out.

The University.

Mr. C. L. Boulenger, M.A., King's College, Cambridge, has been appointed lecturer in zoology as successor to Mr. Leonard Doncaster, M.A. Dr. Leonard G. Parsons has been appointed assistant lecturer in pathology and bacteriology to succeed Dr. Leonard Mackey. Mr. P. P. Cole, M.B., Ch.B. Birm., F.R.C.S. Eng., has resigned his post as senior demonstrator in anatomy.

May 10th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Fight Against Tuberculosis.

THE Manchester and Salford District Charity Organisation Society is opening a special consumption fund, relief from which will be confined to the sufferers from phthisis. In the special appeal it is stated that families where the bread-winner is not only too ill to work but is a source of extreme danger to his family are among the most distressing cases with which the society deals. It is hoped through this fund to maintain the strength of a number of patients waiting for hospital treatment, and also to protect the children who may through want be in added danger of contracting the disease. The work will be done in close union with existing efforts and no help will be given in any case which has not been visited by the sanitary officers and approved by the health

departments of Manchester and Salford. So far the response is encouraging. But the coöperation of the class among the public which suffers most is still urgently required here. Spitting in public is indulged in by a very large proportion of the less civilised sections of our people. The disgusting habit has compelled the tramways department to take vigorous action. Numerous complaints have been received, and to check the evil inspectors have now been placed on the cars to take the names of offenders. At the Manchester police-court on May 6th many summonses were heard, and five defendants were each fined 21*s.* and costs.

Mersey and Irwell Committee.

At a meeting of the Mersey and Irwell joint committee held on May 4th under the chairmanship of Dr. Hewitt, it was stated that the estimate for the year ending March 31st next was £4368. One half is to be levied at once and the other half next October. The clerk was directed to call the attention of the unfortunate Salford corporation to the fact that the effluent from the Salford sewage works was the worst on the month's list. The corporation is also to be informed that unless it takes steps to improve the treatment of the sewage the matter will be again brought before the court and the infliction of penalties will be asked for. Salford may be sympathised with, as it is a difficult and costly task she has to undertake, but it must be accomplished. At the same time, all the authorities higher up the Irwell and its tributaries must be similarly treated, as she ought not to be asked to deal with the filth that comes down to her from the streams above.

May 10th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University: Medical Curriculum.

As has been indicated in THE LANCET from time to time, there has been much dissatisfaction amongst the lecturers in the Edinburgh Medical School with the curriculum. This found expression in the report approved by the Edinburgh Pathological Club, which was summarised in THE LANCET. It found further expression at the meeting of the General Council of the University held on Oct. 29th, 1909, when it was remitted to the Business Committee "to consider and report as to the desirability of procuring by an amending ordinance of the University Court or otherwise further improvements in the medical curriculum and examinations." In view of the remit the Business Committee appointed a special committee to consider the question of medical education in Edinburgh. This special committee was of opinion that the questions could be best treated under two main heads: (1) the medical curriculum regarded purely as a course of study; and (2) the mutual relations between the bodies concerned in medical education in Edinburgh—viz., the University, the extra-mural school, and the Royal Infirmary. With this double object in view the special committee was divided into two subcommittees. The subcommittee whose duty it was to report on the medical curriculum drew up a report which was accepted by the Business Committee. This report was submitted to the meeting of the General Council at its statutory meeting on May 4th. It approved the report and directed that it be sent to the University Court. The report of the second subcommittee has not been submitted—in fact, it has yet to deal with the questions on which it has to report. An outline of the suggested changes in the curriculum is of sufficient interest to be summarised here. The committee is of opinion that it is advantageous to the student to begin the curriculum in May instead of in November, but does not press the point. With regard to the subjects of the first professional examination—botany, zoology, chemistry, and physics—it is suggested that instruction in these subjects ought to be accepted from any school or college approved by the University Court and attended prior to registration, and that students from such institutions should be admitted to examination in one or more of these subjects without attendance at the University class on the subject. The passing of these subjects would not be held to constitute any part of the five years' course of professional study. The time table incorporated in the committee's report begins with the *first winter;* in it the student attends 100 lectures on both anatomy and chemistry and 40 lectures on physics; practical chemistry gets 80 hours, practical physics 30 hours, and tutorial anatomy 40 hours. The afternoons provide two or three hours daily for practical anatomy. At the end of the winter the examinations in chemistry and physics ought to be passed. In the summer botany lectures are given 50 hours, zoology lectures 40 hours, and 50 hours each to practical botany and practical zoology; the afternoon is reserved for practical anatomy. At the end of the session the examinations in botany and zoology ought to be passed. In the *second winter* anatomy demonstrations have 100 hours, physiology lectures and demonstrations 100 hours, practical physiology 80 hours (two hours two days a week to sections of the class), and practical anatomy 120 hours in the forenoons and two or three hours each afternoon. In the summer practical histology, first division, two hours four days a week, and second division two hours four days a week at different hours; anatomy demonstrations have 50 hours; and practical anatomy has two to three hours every afternoon. The examinations in anatomy and physiology should be passed in July. The *third year* includes the winter and the following summer, so that the period includes 150 academic days, or 30 weeks; surgery lectures have an hour three days a week, pathology lectures three days a week, materia medica two days a week, and practical pathology and bacteriology 60 to 70 hours. Hospital work on the surgical side, including post-mortem examinations, is begun and extends from 10 A.M. to 1.30 P.M. daily. In July there is an examination in elementary pathology and materia medica (including pharmacology). The *fourth and fifth years* are devoted to medicine, surgery, obstetrics, gynæcology, and special subjects. The most important changes are that systematic lectures on medicine and surgery are given on alternate days, so that there are 90 hours for each (Saturday morning being utilised). Therapeutics have 40 hours given in two days a week, and advanced pathology has 20 lectures allocated to it. Obstetrics have 60 lectures, and gynæcology has 30. In the fifth winter there are 30 lectures on advanced surgery, and 60 on advanced medicine, while operative surgery has 60 hours. Clinical medicine, surgery and gynæcology, extend from 10 A.M. to 1.30 P.M. daily. The changes proposed would add practical instruction to theoretical in physics; the second professional examination in anatomy and physiology would be taken at the end of the second year of study; the third year is given to pathology and materia medica, and the student begins hospital work and the study of surgery; the fourth and fifth years are devoted to medicine, surgery, obstetrics, gynæcology, public health, medical jurisprudence, and special subjects, as fevers, insanity, &c. In addition, a short course of lectures on therapeutics and another on advanced pathology have been introduced. The report recommends the adoption of a regulation to the effect that attendance on any of the subjects of the third and final examinations shall not be allowed to count until both subjects of the second professional have been passed.

Outbreak of Scarlet Fever at Alyth.

There have been 50 cases of scarlet fever in about three weeks in Alyth, and suspicion has been directed towards a dairy of 17 cows outside the burgh boundary, which disposes of most of its milk within Alyth burgh. Official inspection of cows led to a divided opinion, and it was decided to seek the opinion of the Local Government Board. Therewith the county officials, members of the district committee, and members of the Alyth local authority met two Local Government Board officials on May 7th, and it is understood that the county officers instructed the closing of the dairy for ten days pending inquiries. The dairy in question is one of the cleanest and best kept in Perthshire, and there has been no case of fever amongst those in any way connected with it.

Medical Officer's Report for Ross and Cromarty.

Dr. Bruce of Dingwall, in submitting his nineteenth annual report of the public health of the county of Ross and Cromarty for 1909, states that the general health, judged by the death-rate, continues to improve, the mortality figure being 13·938 per 1000, as against 15·426 for 1908 and 15·870 for 1907. He continues: "In the different districts of the county the highest mortality-rate occurred in the south-western district and the lowest in Lewis. As I have remarked in previous reports, if the returns were corrected

by the mortality at different ages, the figure, more especially in the western and south-western districts, would be reduced in their case by at least 2, if we are to institute a fair comparison with the Lewis district, for example. In the former, as shown by the low birth-rate, the proportion of young and middle-aged is much less than in the latter, on account chiefly of the steady emigration of the working classes to America, Australia, and the colonies generally. From the Lewis, on the other hand, there is comparatively little outflow of population. Again, looking at this question from another point of view, in the south-western district two-thirds of the deaths recorded were of persons over 60 years of age, while in the Lewis only half had reached that age, while the conditions of life are much the same in both districts. The inference is fair, that in the one case there was a much larger infusion of young lives than in the other, with a correspondingly diminished number of deaths to be recorded. Passing to the birth-rates, the general rate all over the county is 20·213, as against 21·575 in 1908. In the insulo-rural districts the rate is 19·1, and in all Scotland 26·3." With regard to the need for medical inspection of schools, Dr. Bruce writes: "In a part of the country such as Ross-shire, where the natural conditions are such as favour the public health, there are few influences prevailing which are calculated to have an openly injurious effect; and consequently, measures for their improvement are in many respects uncalled for. One of the most real advances in combating disease is a better knowledge of the laws of health. Hence I have continued to advocate teaching and practical training in hygiene in our public schools. With the advent of the medical inspector there is sure to follow large improvement in this respect. It cannot be expected that old folks will change their ways, however strongly reforms may be urged upon their notice, and I do not believe it advisable to push compulsion too soon or too far. The people must, in my view, be educated first to understand the necessity for ultimate resort to the law in certain cases before trying to enforce it. Much has been said, for example, as to the filthy and squalid state of many of the houses of our Highland fishing and crofting populations. No doubt, æsthetically, such accusations on this ground are well founded. But when brought to the test of hard statistics the fact remains that in such habitations there exist, on the whole, more than healthy men and women."

Death of an Aberdeen Medical Man in Ceylon.

Information has been received in Aberdeen of the death of Dr. James Craib, at the age of 57 years, youngest son of Mr. John Craib, Strathmore, Coull. Dr. Craib was educated at the University of Aberdeen, where he had completed his curriculum as a medical man by the time he was 21 years of age. Shortly after he went to Ceylon, where he has carried on his profession successfully ever since, passing through several grades of the Government service till he reached the position of medical officer in charge of a province. His wife died some years ago, but he is survived by a grown-up family. Dr. Craib was a keen sportsman and extremely popular with those with whom his work brought him in contact.

May 10th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Statistics of Venereal Diseases in Germany.

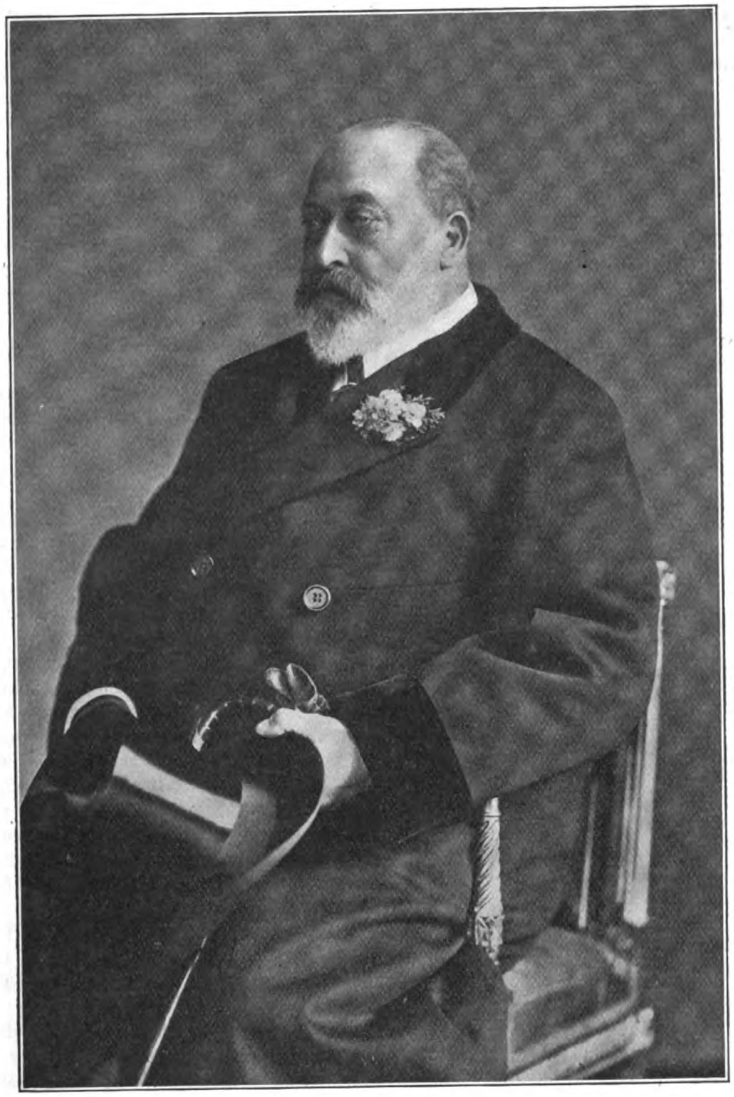
AT a recent meeting of the Society for Social Medicine Dr. Blaschko read a paper on the prevalence and distribution of venereal diseases in Germany. He said that reliable statistics on this subject were difficult to obtain except with regard to the army. It has been found that venereal diseases are less frequent in the German army than in any other European army. In the German army these diseases have shown a steady and progressive decrease during the last 20 years, and are in the various garrison towns less frequent among the soldiers than among the civilian population. In a collective investigation carried out on behalf of the medical department of the Prussian Government 41,000 venereal patients were registered, of whom 11,000 were syphilitic. Obviously this number is much too small, and it has to be further remarked that only a fraction of the medical profession answered the questions of the Government schedule. From the statistics of the collective investigation it appeared that the proportion of persons under medical treatment for venereal disease per 10,000 of the urban population was as follows: in Berlin, 142 men and 45 women; in cities of more than 100,000 inhabitants, 100 men and 28 women; in towns having from 30,000 to 100,000 inhabitants, 58 men and 17 women; in towns of less than 30,000 inhabitants, 45 men and 17 women; and among the general rural population, 7·95 men and 2·7 women. In the army the proportion of venereal patients was 15 per 10,000. Classifying the cases as between town and country, 78 5 per cent. of all the patients belonged to the urban and 21·5 per cent. to the rural population; whilst in Prussia, on the contrary, 76·5 per cent. lived in the country and 23·8 per cent. in towns. In Prussia 28·2 men and 9·0 women per 10,000 of the whole population were under medical care for venereal diseases. Of the patients 54 per cent. suffered from gonorrhœa, 7 per cent. from soft chancre, and 39 per cent. from syphilis. The latter number is obviously too high, the overstatement being caused by the fact that the duration of treatment is greater for syphilis than for gonorrhœa, and that therefore a greater number must be registered on a certain day. In fact, only 10 per cent. of fresh cases may occur within a year. Dr. Blaschko had collected statistics from sick clubs, in which certain trades or professions preponderated; he found that in a club consisting largely of clerks the proportion of members suffering from venereal disease was 16 per cent.; in a workmen's club it was 4 per cent.; and in both clubs of the students of the Agricultural and of the Veterinary College it reached the high number of 25 per cent. It was an interesting fact that in Southern Germany the amount of venereal disease is smaller, but the number of illegitimate children greater than in Prussia. In the colliery and mining districts of Rhenish Westphalia the number of venereal cases is very small; this is due to the circumstance that the working population, which is predominant in that district, marries at a rather early age and is therefore less exposed to infection; in that part of the country there is also less prostitution than in the great commercial towns and seaports, in the garrisons and university towns, and in places with many foreign visitors. Dr. Blaschko declared himself unable to explain the differences between the number of venereal cases in Northern and in Southern Germany, the disparity being obvious at the examination of army recruits. The proportion of venereal cases per 1000 recruits coming from various cities and constituent States of the Empire was as follows: Berlin, 41; Altona, 31; Kiel, 25; Nuremberg, 12; Metz, 8; Prussia, 7·8; Saxony, 13·5; Bavaria, 4·8; Würtemberg, 3·3; and Baden, 2·5. Venereal diseases are obviously on the increase; this is especially shown by the number of patients suffering from general paralysis admitted into the Prussian lunatic asylums; these patients during the period 1888–90 consisted of 995 men and 222 women, whilst during the year 1908 the number rose to 2279 men and 660 women.

May 10th.

CHILD-STUDY SOCIETY.—The annual conference of the Child-Study Society, consisting of constituent societies at Birmingham, Cheltenham, Dundee, Edinburgh, Exeter, Halifax, London, Liverpool, Manchester, and West Kent, will be held at Tunbridge Wells on May 19th, 20th, and 21st in the Town Hall. The presidential address will be delivered by Sir James Crichton-Browne on Thursday, May 19th, at 9 P.M. On May 20th three addresses will be given, at 11 A.M., 3 P.M., and 8 P.M. respectively, the subjects being: The Social Life of a Child at a Co-Educational School, by Mr. John Russell, headmaster of King Alfred School, Hampstead; The Child as Citizen, by Mrs. Higgs, author of "Glimpses into the Abyss"; The Hand as the Gate of Knowledge and Social Relationship, by the Hon. Sir John A. Cockburn, K.C.M.G. On May 21st an address will be given by Miss Alice Ravenhill, at 11 A.M., on the Result of an Investigation into the Play Interests of English Children, based on a Preliminary Examination of 10,000 Returns. Mr. C. Lowry, The School House, Tonbridge, will invite the delegates to lunch on Saturday. The meetings on Friday and Saturday (except the council meeting) are open to the public.

The Death of the King.

WE have received from the late King's physicians the following authorised report of the last illness of His Majesty:—



The brief illness of the King and its rapid and fatal termination can only be understood after reference to his physical condition as a whole, when the sequence of events becomes clear.

His Majesty had for some years suffered from emphysema with an attendant bronchial catarrh, the signs of which were permanently present at the bases of the lungs. On several occasions digestive disturbances and other symptoms had caused his medical attendants to realise that His Majesty no longer had the reserve of constitutional power which stood him in such splendid stead after his serious operation in 1902, and that any intercurrent catarrhal or bronchitic attack of a severe kind would at once call upon both heart and lungs for their fullest effort. It must here be said that those around him knew how earnestly concerned he was at the present strained position of political affairs, and this fact should not be lost sight of in an all-round consideration of the King's health.

On March 7th, it will be remembered, His Majesty started for Biarritz to obtain a little leisure from these anxieties. He had received some months previously a vaccination treatment which it was hoped would secure him for some time from catarrhal attacks. He broke the journey in Paris, and on the first night there had a severe attack of acute indigestion with subsequent dyspnœa and considerable cardiac distress. The symptoms had arisen out of exertion, and yielded promptly to treatment. The next day His Majesty exchanged visits with President Fallières and fulfilled his ordinary social engagements. But on arrival at Biarritz it became clear that he had contracted a chill which developed into a regular bronchitic attack, the raised temperature, accelerated pulse and respirations, and the physical signs in the chest occasioning his physician no little anxiety. The attack lasted 10 days, during several of which he was confined to his bed, but the symptoms passed off, and for the rest of the visit His Majesty led his usual life, making excursions, and entertaining quietly.

His Majesty came back from Biarritz on Wednesday, April 27th, better in every way, and at once took up the thread of his very full life. On Saturday, April 30th, he went down to Sandringham feeling a little unwell, and on Sunday, after attending service, he spent a long day looking at some extensive new planting and gardening alterations, with the result that a fresh chill was contracted. On Monday, May 2nd, he returned to London in very cold weather, feeling somewhat chilly and out of sorts. He, however, fulfilled a social engagement to dinner. That evening, on returning from dinner, His Majesty was seen by one of his physicians, who found him complaining of some dyspnœa, with slightly raised temperature and quickened pulse and respirations; distinct bronchial crepitations were present over the bases of both lungs. He passed a disturbed night. On Tuesday morning, May 3rd, the symptoms had abated, he felt better, and the temperature was normal, but he suffered from much cough and expectoration and considerable dyspnœa. Notwithstanding the urgent desire of his physicians that he should rest quietly, His Majesty again received official visitors and gave audiences. That evening at 7 P.M. the King told his physicians that he felt ill, and he had more than one attack of severe dyspnœa during that night, the attacks not being occasioned, as hitherto, by exertion. On the morning of Wednesday, May 4th, the temperature was 99° F. and the pulse 90, and he complained of irritation in the throat. He was seen by the throat specialist who had seen him on former occasions, but the only condition found was catarrh, and there was now an irritable and catarrhal condition also observable in connexion with other organs. His Majesty again, however, gave several important audiences. At 6.15 P.M. a consultation was held by his three physicians who found that the two consecutive bad nights and some severe attacks of dyspnœa had told seriously upon His Majesty. There was a very imperfect entry of air at both bases, and much fine bronchial crepitation; the right side of the heart was embarrassed. The temperature was normal and the respirations 34. One of his physicians remained at the Palace, and the King passed a disturbed night. On Thursday morning, May 5th, His Majesty's condition was not improved; he again, however, gave audiences. The attacks of dyspnœa were more frequent and distressing, and with increasing cyanosis were gravely suggestive of threatened cardiac failure. In the afternoon the Queen arrived from the Continent, and the fact that the King was not at the station to meet her was the first indication to the public that His Majesty was indisposed. With the permission of the King the physicians now issued their first bulletin that "The King is suffering from bronchitis and has been confined to his room for two days. His Majesty's condition causes some anxiety," which appeared in some of the evening papers, but not until it had been seen by His Majesty, who somewhat modified its terms. Sir Francis Laking and Sir James Reid remained at the Palace. Up to 4.30 A.M. on Friday morning His Majesty had a better night, but in the early hours of Friday he had several severe attacks of dyspnœa, and when visited that morning by his physicians it was at once seen that the gravity of the symptoms had increased. A bulletin was issued stating, "The King has passed a comparatively quiet night, but the symptoms have not improved and His Majesty's condition gives rise to grave anxiety." Thereafter His Majesty's condition grew rapidly worse. He had more than one attack of dyspnœa of a dangerous character following upon slight movements, from which he was only rallied by powerful remedies. About 3 P.M. consciousness began to fail, and the third bulletin was issued stating "The King's symptoms have become worse during the day, and His Majesty's condition is now critical." Consciousness never completely returned. The end came at 11.45 P.M., after a prolonged period of perfect calm.

KING EDWARD VII.

(From a photograph by Stuart, Richmond, Surrey.)

A BRIEF BIOGRAPHICAL SKETCH.

No extended biographical notice of his late Majesty will be expected from us, but a brief record of his life, laying stress on the particular places where he entered intimately into medical affairs, should be given.

King Edward VII. was born on Nov. 9th, 1841, at Buckingham Palace, where, on May 6th, 1910, he died, having reigned over the British Empire for a little more than nine years. The eldest son of Queen Victoria, though not her eldest child, his birth was acclaimed with great rejoicing by his mother's subjects. The importance of his early training for the high position to which in the course of nature he should succeed was the subject of profound solicitude to his parents. The Prince Consort, his father, was well fitted for the task of taking counsel with the Queen in such a matter, while the views of his friend and adviser Baron Stockmar undoubtedly had great weight with both parents. As a result the Prince passed through the various stages of preparation under governesses and tutors; went, without, however, enjoying the full advantages of university life, to Oxford and to Cambridge; travelled and received an education calculated to broaden his mind, to inculcate the precepts and information then deemed suitable for the young, and to afford detailed as well as general knowledge of his future subjects, their lives, their interests, and their aspirations. The records left by his parents and his instructors contain proof of the intelligent and lovable disposition which he evinced in these early years. Among the university professors whose names are associated with the educational guidance of the future Sovereign may be mentioned Max Müller, Goldwin Smith, and Charles Kingsley, and it may be added that during a period of several months spent at Edinburgh he had the advantage of being introduced to the study of natural philosophy by Dr. Lyon Playfair (afterwards Lord Playfair), when, no doubt, there was awakened in his mind that interest in scientific progress and that power of grasping and appreciating its import which he exhibited in so perceptible a degree throughout his life. Military training, and the studies of history, ancient and modern, and of modern languages, were not forgotten, the last forming no unimportant part of the equipment of a Prince who throughout his life was to know men of all nations, meeting them in their own countries, and receiving them with cordial hospitality in his own.

His early travels included a visit to Ireland with his parents in 1849; two tours on the continent as well as walking tours with tutors; and in 1860 he made his first voyage of importance, proceeding to Canada, where he laid the foundation-stone of the Dominion Houses of Parliament, and where the memory of a shy, pleasant boy, who was extraordinarily easy to amuse, still lingers. But the time for entry more definitely into public life was upon him. In 1861 the Prince Consort died from typhoid fever, and the effect of his death upon the public life of the widowed Queen is a matter of history. This tragedy deprived a family of nine children of the guidance which, had their father survived, would no doubt have had a powerful influence upon their early development; also, by causing the Queen to lead for many years a life which, so far as social and public functions were concerned, was one of seclusion, there was cast upon the young Prince of Wales the duty of representing royalty in England both in society and in the eyes of the bulk of his mother's subjects. During the year of mourning for his father he made a journey to Egypt and the Holy Land accompanied by Dr. A. P. Stanley (afterwards the famous Dean of Westminster), to whom the Queen's attention had been drawn by his book "Sinai and Palestine." Upon their return, having come of age, the Prince of Wales took his seat in the House of Lords, following closely upon which came that event of supreme importance in his life—his engagement to the beautiful Danish Princess. In 1862 a marriage was arranged between the Prince of Wales and the Princess Alexandra, daughter of King Christian IX. of Denmark, and the wedding took place on March 10th in the following year. It was a union welcomed by the British nation for racial and political reasons, and the grace and charms of the bride won for her from the first a place in the warm hearts of the people at large. That place she has never for a moment lost either as Princess or as Queen, and it is difficult to estimate to how great an extent the personal affection of his subjects for the late monarch was due to and was strengthened by his association in their minds with his wife, with the upbringing of the family which she bore him, and with the performance with her at his side of those social and public functions which ever gained distinction by her presence. From this point his life has been lived so entirely in the light of day that no summary of a historical career need be attempted. At home and abroad, at the Court and in the country, sitting on Royal Commissions, mingling with his future subjects at their sports, and testifying on public occasions to the merits of all useful movements, the Prince of Wales became known in a singularly personal manner to all his subjects. Thousands upon thousands had heard him speaking upon the social progress of the empire at different functions, and always what he said came home as the expression of a fine and well-balanced intelligence and of a broad and sympathetic humanity. He was well understood by his people; and when in 1874–75 he made his long and interesting tour through India the same social wisdom and personal qualities made his journey a prolonged diplomatic triumph. We may add that on that journey through a tropical country, amidst fatiguing ceremonials and visits in which pleasure was combined with arduous public duty, the health of the Heir Apparent was naturally a matter of considerable solicitude to his medical attendant. This fact was duly perceived by the Prince of Wales, and formed one of the reasons for his deep interest in medicine.

In recording the life of Queen Victoria[1] we stated that that great ruler was always a good friend to medicine. The same may be said of her son, the late King, and with emphasis, because of the addition that as a man having great capacity for work and activity of mind and body he was ever able to give strong practical

[1] THE LANCET, Jan. 26th, 1901, p. 279.

assistance where it was needed and when his sympathy was genuinely roused. In particular was he interested in the promotion of everything that might tend to bring the best aid of medicine and surgery within the reach of all, and in the wide employment of any scientific development which might mitigate or, haply, prevent the spread of dangerous disease. For his sympathy with, and his interest in, the work done by the physician and the surgeon he had some personal cause. In the autumn of 1872 he contracted typhoid fever while paying a visit at a nobleman's country seat, and it may be added that two others there present, Lord Chesterfield and a groom, were similarly affected and died. Those who are middle-aged among his subjects will remember the illness of the Prince, the deep anxiety of the nation, the watch at his bedside throughout the kingdom, the constant issue of the eagerly read bulletins which made familiar to high and low the names of Jenner, Gull, and Lowe. Then came the growing feeling of relief from tension when more favourable symptoms were announced, and then the joy when convalescence followed, culminating in a great day of national thanksgiving. 20 years later the Prince and Princess of Wales saw their second son George, now our King, struck down with the same disease that had so nearly cost his father his life, and watched him recover, though fortunately with no reason for the same anxious alarm, but almost immediately afterwards their elder son, the Duke of Clarence, was taken from them and the nation as the result of an attack of influenza. Truly, it may be said that his late Majesty's familiarity with practical medicine, its accomplishments and its limitations, was very close. It was therefore in no way to be wondered at that in his sympathy with the subjects over whom he ruled the King was ever ready to keep himself in touch with all that was being devised and done to retard the incidence of that death which must come to all; and that in particular he should have taken a keen interest throughout his life in the provision by voluntary charity of that aid in sickness which otherwise would be beyond the reach of the humbler classes of the population. King Edward's Hospital Fund, initiated by him as Prince of Wales in 1897 in commemoration of Queen Victoria's Diamond Jubilee, is a conspicuous monument, reared to remind us of his sympathy with and interest in the work of the hospitals, and of his practical sagacity and businesslike power of anticipating results.

And medicine was again to play an important part in his life. On Jan. 22nd, 1901, by the death of Queen Victoria, King Edward VII. became King, but before the rite of coronation could enable him to formally ascend the throne of his ancestors he had to incur once more a debt to science. His coronation was fixed for June 26th, 1902, and at midday on June 25th London, bathed in summer sunshine, was busy decking itself for the coming pageant which was to be followed on the 27th by a prolonged progress of their newly-crowned majesties through the streets. What followed none who witnessed it will forget. The astonishing announcement that at the last hour the coronation was indefinitely postponed owing to the King's illness was immediately succeeded by the news that an operation had already been performed, of the seriousness of which in the circumstances medical men and most laymen were fully aware. A few days later, however, the bonfires prepared to signalise the coronation were lit in token of joy that the King was out of danger. He showed great recuperative powers, and, as all remember, he was able to bear the fatigue of his coronation on August 9th. He had succeeded to the throne when the long war in South Africa was dragging to its close, taking its toll from all ranks of his army and putting a severe strain upon his country's resources. The war ended just before the date first fixed for the coronation of King Edward and Queen Alexandra, and Lord Kitchener, the general who had conducted it in its later stages, was not the least conspicuous figure in the procession on the day of the actual ceremony. From that time onwards his late Majesty's reign was one of peace, and it has been reckoned to be due to him in no small measure that during that period the peace of Europe has been preserved unbroken. The full extent of the influence which he exercised has yet to be ascertained and appreciated, but of its beneficent tendency there can be no question any more than of the conspicuous ability which he evinced as King in the performance of functions of Statecraft which he was not called on to exercise while his mother lived.

Among the most distinct occasions on which the King manifested in a practical manner the interest which he felt in the progress of medicine may be mentioned the following. In 1874 he presided at the Eighteenth Festival Dinner of Epsom College, having been present in 1855 when his father, the Prince Consort, declared the building open. In 1895 he laid the foundation stone of the lower school at the College. In 1891 he accepted the presidency of the Congress of Hygiene and Demography which met that year in England. In 1896 the financial position of Guy's Hospital was brought to his attention. He presided at a dinner of gentlemen met together to support the charity, and by actions and words brought to the hospital a measure of instant relief that could have been obtained in no other way. He laid the foundation-stones of many of our great medical charities both in London and the provinces, and accepted the Fellowship from the Royal College of Physicians of London in 1897, and from the Royal College of Surgeons of England in 1900. He honoured with his friendship many members of the medical profession, and on those occasions when he was under their care his attention to the relations that must prevail between patient and doctor was scrupulous. Medicine has lost in King Edward VII. a true friend.

During his whole life as Prince of Wales and as King he was a keen sportsman, devoting himself in particular to shooting and to racing, but taking also a lively interest in yachting. His successes on the turf before and after his accession to the throne were a source of satisfaction to a large class of his subjects, many of whom forgot that the King pursued amusement with characteristic zeal and heartiness in the intervals of enormously hard work on behalf of his country. To this sort of misconstruction he was often the victim. Many saw the motive of amusement only in those visits abroad for the sake of rest which he paid during recent years in the spring season. From such a visit to Biarritz he had returned but a few days before his last illness, and, as will be seen by the authorised statement of the course of events in that illness, the change of air and environment had brought much benefit, though Biarritz this year has had a most rigorous spring. But a visit to Sandringham on the Saturday and Sunday before his death brought back bronchitic symptoms, which had shown themselves while he was on his holiday. On the afternoon of Thursday, May 5th, a few people in London learnt with concern that the King was suffering from bronchitis. On the following morning all were aware with a shock of horror that his medical attendants were finding his condition one causing anxiety. The public was compelled to recognise the full import of the more serious bulletins issued during Friday, and knew on the morning of Saturday, May 7th, that just before midnight the King had breathed his last. He died literally in harness, transacting business and granting audiences up to the day of his death. It was characteristic of him that he should die in this way, for throughout the whole of his life he had refused to allow the plea of sickness to

stand between him and the performance of his duties. The general condition of his health, as revealed in his physicians' statement, shows that the train of events and their sad culmination could be no matters of surprise for those in his nearest confidence; while the revision by the patient of the first bulletin issued proves the spirit with which he faced the increasing gravity of the symptoms. We allow ourselves to make one comment on the authoritative statement of His Majesty's illness. The last audiences alluded to were of the briefest possible description and entailed no fatigue upon the King. Sir Francis Laking, Sir James Reid, Sir R. Douglas Powell, Dr. Bertrand Dawson, and Dr. StClair Thomson did all that was possible for him in the circumstances, but it is abundantly clear that the reserves of vitality could not stand the strain put upon them.

The tragedy of the rapid close to his great career has been even more vividly brought to all minds by the moving message of the Queen-Mother to his sorrowing people.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE statement of plague mortality for the week ending April 2nd shows a rise of 2962 in the number of deaths recorded throughout India, the totals being 22,198 for the previous week and 25,160 for the week under report. In the provinces the deaths occurred as follows: Bombay Presidency, 687; Bengal, 3021; the United Provinces, 9139; the Punjab, 8655; Burma, 582; the Central Provinces, 915; Rajputana, 2012. In the United Provinces the worst areas were Muttra, 1261; Ballia district, 1173; Unao district, 679; Azamgarh district, 759.

The Rise in Indian Opium.

The reason generally given for the phenomenal rise in the price of Indian opium in China is that inveterate users of the drug are laying in stocks to last them during the term of their natural lives! These are men of a certain age who are not prepared to forego the pleasures of the pipe in spite of all the edicts from Peking. They are therefore purchasing largely now, and as the supply from India has been curtailed prices are mounting up every week. In fact, Indian opium in China now fetches its weight in silver. It is the Malwa variety which most appeals to smokers, and as it improves with age fancy prices are paid for it. Malwa opium 15 or 16 years old is to the Chinese connoisseur what a vintage port is to the European wine-drinker. The Bengal drug, on the other hand, does not keep its flavour more than a few years after it has been put on the market, but it has to be purchased now as the Malwa sales in India have been anticipated by a year and no shipments will be made from Bombay in 1910–11. Looking at the position in China, it is plain that the cultivation of the indigenous drug has really been checked and that local production is growing smaller every year. But Szechuen, the province with the largest area under poppy, has not yet obeyed the Imperial mandate, though its neighbour Yunnan has loyally conformed to the Peking orders. Much depends upon the personal character of the various viceroys, who have full power to stop cultivation. In Szechuen the highest officials are said to be deeply interested in opium, and the present viceroy is not inclined to move seriously in the matter of prohibition. He has, to a certain extent, popular opinion on his side, as the cultivation of opium is general and money flows into the province during the export season. The Central Government is not apparently prepared at present to interfere with this lucrative business, and the reformers of the Young China party cannot coerce the viceroy, who is admittedly a strong provincial ruler.

The Proposed New Hospital for Mussooree.

An appeal has been issued by Major G. T. Birdwood, I.M.S., civil surgeon of Mussooree, on behalf of a new cottage hospital, as the present one is considered to be too small and too far out of the way for the needs of Mussooree, but Rs.50,000 is a big sum to collect, especially when one bears in mind the somewhat numerous other charitable institutions Mussooree supports. Nevertheless, a hospital such as is proposed at Bassett Hall on the Camel's Back is not a merely local institution. It appeals to, and deserves support from, the whole of the Upper Provinces, for there is only the Ramsay Hospital at Naini Tal available at present. It should be clearly borne in mind that the cottage hospital does not in any way interfere with existing nursing homes, but is intended for those who cannot afford the fees charged at these homes, which have, of necessity, to be *paying* concerns.

A School of Tropical Medicine for Calcutta.

Lieutenant-Colonel P. Hehir, I.M.S., senior medical officer at Lansdowne, states in the *Allahabad Pioneer* that there is no country in the world in which a School of Tropical Medicine is more urgently called for than in India, or in which a greater number of people would be benefited by the establishment of such an institution. Calcutta is the place in the Indian Empire which offers unrivalled and almost unlimited facilities for scientific education in tropical medicine. Having visited practically every School of Tropical Medicine in the Old and the New World, Colonel Hehir is in a position to state that "in no other place is such a variety of tropical diseases to be met with as in Calcutta, in which city instances of over one-half of the diseases peculiar to the tropics are to be found." Further, its connexion with the East generally, its immense shipping trade, brings from different ports cases of several forms of tropical disease not indigenous to India. In the Medical College and Medical College Hospital of Calcutta there is ready at hand a pathological museum rich in its collection of specimens illustrating the effects of tropical disease, which specimens have been gathered since the opening of the Medical College somewhere about 1880. The proximity of the Calcutta museum, with its entomological and other collections intimately associated with the scientific study of tropical medicine, is an additional reason for the selection of the metropolis for the School of Tropical Medicine. The new institution should afford every facility to its students to acquire a thoroughly sound and practical training in tropical medicine and all its branches, and of obtaining a degree or diploma in tropical medicine after going through the complete curriculum of studies and work. Such a degree or diploma could be readily included by the Calcutta University in the list of qualifications which it grants.

April 16th.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the First Professional Examination for the Licence in Dental Surgery held this month, the following candidates were approved in the under-mentioned subjects. The list includes the name of one lady, Miss Lily Fanny Pain:—

Mechanical Dentistry and Dental Metallurgy.—Eric Bernard Armitage, Royal Dental Hospital; Norman Arthur Austin, Birmingham University; David Harold Barr, Guy's Hospital; Reginald Hugh Basker, Bristol University; Sydney William Bevis and John Edgar Davies, Guy's Hospital; Thomas Clement Davies, Royal Dental Hospital; Robert Lester Donn, Guy's Hospital; Percy William Flook, Bristol University; Eldred Leslie Fraser, Guy's Hospital; George Cowley Gell, Royal Dental Hospital; John Wesley Gilbert, Bristol University; Victor FitzHerbert Hedworth Golledge, Guy's Hospital; Owen Hairsine, Royal Dental Hospital; Edwin Joseph Handford, Bristol University; Samuel George Howle, Birmingham University; Alfred Morgan Hughes, William Sanders Johnstone, Thomas Clatworthy Kidner, and Aurelius Percy Kincaid-Smith, Royal Dental Hospital; Bernard Lethaby-Morgan, Bristol University; Frank Lodge and Ewart McArd, Royal Dental Hospital; George Matthews and Charles Harold Medlock, Guy's Hospital; Herbert Vincent Morley, Royal Dental Hospital; Charles Douglas Neale and Raul Orozco-Casorla, Guy's Hospital; Lily Fanny Pain, National Dental Hospital; Thomas Harold Parsons, Birmingham University; William Linnell Partridge, Guy's Hospital; Herbert James Pegler, Royal Dental Hospital; Harold Neish Purdom, Guy's Hospital; William Edwin Acland Sampson, National Dental Hospital; Isidore Gittleson Samuels, Guy's Hospital; Frederick John Smith, Sheffield University; Claude Hamilton Stainer, Reginald Douglas Tanner, Francis Joseph Tipper, and Reginald McKenzie Veale, Guy's Hospital; Harold Walker, Manchester University; Frank Roland Wallis, Guy's Hospital; Harold Wardill, Royal Dental Hospital; William Henry Whitworth, Manchester University; Edgar Roskelly Williams, Guy's Hospital; Malcolm Lloyd Williams, Birmingham University; Charles Henry Wilson, Bristol University; and Lewis William Wilson, Royal Dental Hospital.

Mechanical Dentistry.—Henry Kiver Allison and Horace Arthur

Arkill, Royal Dental Hospital; Henry Leonard Bailey, Guy's Hospital; Fritz Ernest Bendix, John William Bowen, Francis Edward Stuart Bralisford, and Montague Kempston Butler, Royal Dental Hospital; Gwilym Tremain Davies, National Dental Hospital; Chandulal Manilal Desai and Harold Graham Elliott, Guy's Hospital; Frederick Graham Emanuel and Francis Arthur Everett, Royal Dental Hospital; Guy Leroy Gillett, Michigan University; John Stanley Frank Horton, Royal Dental Hospital; Ernest Sharman Huckett, Guy's Hospital; Samuel Carson Huggins, Royal Dental Hospital; William Symons Lakeman, Guy's Hospital; Thomas Spencer Osmer and Arthur George Drake Pridham, Royal Dental Hospital; Warren Longtoft Roberts and Henry Clifford Robinson, Leeds University; Arnold Victor Shilton, Birmingham University; Thomas Huddlestone Urwin, Durham University; Frank Wisher, Guy's Hospital; and Keith Eric Wood, Royal Dental Hospital.

Dental Metallurgy.—Patrick Boyle, Royal Dental Hospital; Arnold John Chapman, Guy's Hospital; Henry Charles Corke, Guy's Hospital; Philip Lewis Ealand, Bristol University; George Hobbs, Birmingham University; Charles Henry Housden, Guy's Hospital; Michael William Joseph, Birmingham University; Raphael Neft, William John O'Kane, Percy John Peatfield, Charles Joseph Phillips, and John Hampden Ross, Guy's Hospital; Leslie Shovelton, Birmingham University; Richard Reginald Steele, Guy's Hospital; Joseph Leslie Tucker, Royal Dental Hospital; John James Ward, Liverpool University; and Stanley Joseph Frederick Webb, Guy's Hospital.

APOTHECARIES' HALL OF IRELAND.—The results of the last quarterly examinations are as follows:—

FIRST PROFESSIONAL.

Biology.—M. Burke Kennedy and D. J. Chadwick.
Physics.—H. Hutchinson.

SECOND PROFESSIONAL.

Physiology.—J. M. J. Levens and W. MacArgan Scott.

THIRD PROFESSIONAL.

Pathology.—George M. Mayberry.
Pharmacy.—M. Neary.
Medical Jurisprudence and Hygiene.—M. Neary.

FINAL PROFESSIONAL.

Medicine.—W. J. Fletcher.
Surgery.—W. J. Fletcher and W. S. Davoux.
Midwifery.—W. J. Fletcher, W. S. Davoux, G. M. Mayberry, Adam Ardill, and J. V. Pestana.

EXAMINATION FOR REGISTERED PRACTITIONERS.

M. P. Desmond, P. V. Delan, and R. McDonnell.

FOREIGN UNIVERSITY INTELLIGENCE.—*Breslau:* Dr. K. Goebel, *privat-docent* of Surgery, has been granted the title of Professor.—*Düsseldorf (Medical Academy):* Dr. Oertel has been appointed *Dozent* of Otology and Director of the Ear Clinic; Dr. Graf, staff surgeon, *Dozent* of Military Surgery; Professor Joh. Müller of Rostock, *Dozent* of Physiology; and Dr. Köhlisch, staff surgeon, *Dozent* of Bacteriology and Hygiene.—*Jena:* Dr. Martin Zade has been recognised as *privat-docent* of Ophthalmology.—*Munich:* Dr. Max Borst of Würzburg has been appointed Professor of Pathological Anatomy and General Pathology in succession to the late Professor O. von Dr. Bollinger.—*Naples:* Dr. Andrea Ambrosio has been recognised as *privat-docent* of Internal Pathology; and Dr. Francesco Cascella as *privat-docent* of Criminal Anthropology.—*Padua:* Dr. Demetrio Roncali has been appointed Extraordinary Professor of External Pathology.—*Pavia:* Dr. Aldo Patta has been recognised as *privat-docent* of Materia Medica and Experimental Pharmacology.—*Prague (German University):* Dr. Julius Rihl has been recognised as *privat-docent* of Experimental and General Pathology.

THE MIDDLESEX SANATORIUM FOR WORKING-CLASS CONSUMPTIVES.—On April 25th a meeting was held at the Council House, Hounslow, in connexion with the proposal to establish a sanatorium for working-class consumptives in Middlesex. Mr. F. C. Greville-Smith, J.P., presided. Colonel Gerard Clark (originator of the scheme), in addressing the meeting, said that they did not propose to erect an expensive institution at £1600 per bed, like Northwood, but one of £100 per bed. The scheme would be on a 5*s.* basis, to enable all to take part. Donors of £100 would be life governors, and donors of smaller amounts to £100 would elect a governor. They had £500 promised. He had the offer of two sites—one in Buckinghamshire, which he thought too far off, and the other in their own county, the terms of which would be favourable. Sir Richard Douglas Powell also spoke, and said that the sanatorium was intended for the honest working man and should not be looked on as a charity at all. He agreed with the suggestion that while most of the beds should be kept for incipient cases, yet that a wing should be reserved for advanced cases. He thought such cases were not treated on such sympathetic lines as they should be, for it was also part of medical duty to prolong life and to lessen suffering, as well as to prevent disease. The following motion, proposed by Dr. G. A. S. Gordon and seconded by Mr. W. J. Lobjoit, J.P., was agreed to:—

That this meeting is of opinion that a sanatorium in the county of Middlesex, established on an economical basis, for the treatment and education of consumptives, would be a boon to the community and a safeguard to the public health. That a local committee be formed to work in coöperation with similar committees formed, or in the course of formation, in other parts of the county, in furtherance of the provision of such a sanatorium.

PRINCESS ALICE MEMORIAL HOSPITAL, EASTBOURNE.—In furtherance of the decision of the committee of the Princess Alice Memorial Hospital, Eastbourne, at the annual meeting in February last, a public meeting in support of the enlargement proposal was held on May 2nd, the Duke of Devonshire presiding. It is proposed to increase the accommodation at the hospital by the addition of wards to provide 16 beds at a cost of £4000. A resolution was carried opening a fund for the purpose of carrying out the work, and His Grace the Duke of Devonshire and Mr. Sydney Hudson, the former as mayor of the borough and the latter as chairman of the committee, each subscribed £500. There is urgent need for additional accommodation at the hospital. Built on the lines of a cottage hospital in 1883 it provided accommodation then for 12 beds. From time to time enlargements have been made and now the beds number 50. It is found that the hospital must mark time with the rapid growth of the borough and the development of the district around, for whereas in 1901 the number of patients was 331 the figure for 1909 was nearly double, being 659.

A PROPOSED BOARD OF REFERENCE.—At the annual conference of the Incorporated Society of Inspectors of Weights and Measures held on May 6th at the County Hall, Spring Gardens, Westminster, it was proposed that an expert board of reference should be constituted to decide controversial questions of chemistry, hygiene, or physiology, and to assist magistrates when dealing with such questions. This was carried without discussion. It was proposed that the British Pharmacopœia should be made a legal standard for medicinal articles, "but not until a new edition is compiled by the General Medical Council with this object in view," this being adopted with the omission of the words in inverted commas, the opinion of the conference being that the present edition ought to answer the purpose. It was decided that the Local Government Board should have power to fix standards and definitions of purity for articles of food, and to order the nature and amount of preservative or other ingredient in any article of food to be explicitly declared on the label and to prescribe the terms of the declaration. It being thought that "it would create too much opposition," the following recommendation was withdrawn: "That manufacturers of proprietary medicines containing certain potent drugs should be required to declare the composition by label, and that the exemption of proprietary medicines from the scope of the Sale of Food and Drugs Acts should be repealed."

THE FRENCH HOSPITAL.—The forty-second annual banquet of the French Hospital was held at the Hotel Cecil on Saturday, April 30th, under the presidency of M. Paul Cambon, the French Ambassador. He was supported by many members of the Corps Diplomatique, by the two sheriffs of the City of London—the Lord Mayor was unfortunately unable to be present—by almost the whole of the members of the Corps Médical, and about 280 subscribers. The treasurer announced subscriptions to the amount of £3700. Since the last annual banquet a new wing has been added and the interior of the whole hospital has been greatly improved. A new operating theatre has been constructed, with the addition of a room for the administration of anæsthetics and another room for the sterilisation of the surgical instruments. The corridors and staircases have all been lined with white tiles, and the wards have been thoroughly brought up-to-date. Altogether about £5000 have been spent, and the committee and staff are to be congratulated upon the way in which the work has been carried out. The hospital in London, together with its Convalescent Home at Brighton, which contains 70 beds, is a striking monument to the sympathy which exists between the two nations. After the usual toasts had been duly honoured, his Excellency the Ambassador referring in sympathetic terms to the work done by the late Dr. Vintras,

Dr. George Ogilvie, the senior physician, replied on behalf of his colleagues in French, the speech being greatly applauded.

THE ROYAL SOCIETY OF MEDICINE.—The first meeting for the Vaccine-Therapy Discussion to be held at Morley Hall, George-street, Hanover-square, W., has been postponed from Wednesday, May 18th, at 5 P.M., until Monday, May 23rd, at the same place and the same hour.

UNIVERSITY OF BIRMINGHAM.—The Ingleby lectures for 1910 will be delivered in the Medical Lecture Theatre on Fridays, May 27th and June 3rd, at 4 o'clock, by Professor R. F. C. Leith, the subject being Tumours of Body of Uterus. On Tuesdays, June 7th and 14th, at 4 P.M., Professor Peter Thompson will give in the Anatomical Lecture Theatre, Edmund-street, two lectures on Some Early Human Embryos. The lectures will be illustrated with models and lantern slides. Members of the medical profession and students of medicine are cordially invited to attend.

THE CHEMISTS' EXHIBITION.—The Chemists' Exhibition, which was opened at the Royal Horticultural Hall, Vincent-square, Westminster, on Monday, May 9th, represented the sixteenth of the series. That fact alone is evidence of the success of these meetings, and the recent occasion was as attractive as before, and a good many visitors passed up and down the lines of the picturesquely arranged exhibits. Primarily intended for the business side of pharmacy, the exhibition to some extent partakes of the nature of a commercial exchange, but it serves to show also many advances that have been made in pharmaceutical matters, and thus it naturally attracts the attention of medical men. The exhibition closes this week.

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill have a new edition of Vol. II. of "Allen's Commercial Organic Analysis," just ready for publication. This volume has been rewritten under the editorship of Dr. H. Leffmann and Mr. W. A. Davis, B.Sc. The subjects and authors are as follows: Fixed Oils, Fats and Waxes, by C. A. Mitchell; Special Characters and Methods, by L. Archbutt; Butter Fat, by C. Revis and E. R. Bolton; Lard, by C. A. Mitchell; Linseed Oil, by C. A. Klein; Higher Fatty Acids, by W. Robertson; Soap, by H. Leffmann; Glycerol, by W. A. Davis; Cholesterols, by J. A. Gardner; and Wool Fat and Cloth Oils, by A. H. Gill. They also publish an illustrated handbook of "Morbid Anatomy and Post-mortem Treatment," by C. R. Box, M.D., F.R.C.S., F.R.C.P., physician to out-patients, St. Thomas's Hospital.

ROYAL INSTITUTION. — A general monthly meeting of the members of the Royal Institution was held on May 9th, the Duke of Northumberland, K.G., the President, being in the chair. The special thanks of the members were returned to Mr. Henry F. Makins for a donation of £50 to the fund for the promotion of experimental research at low temperatures. The chairman announced that he had nominated the following gentlemen as Vice-Presidents for the ensuing year: Sir Thomas Barlow, the Right Hon. Sir H. Burton Buckley, Sir William Huggins, Mr. A. B. Kempe, Sir Francis Laking, Mr. George Matthey, Sir James Crichton-Browne (treasurer), and Sir William Crookes (honorary secretary). The meeting adjourned to May 23rd, when a resolution of condolence on the lamented death of His Majesty the King will be passed.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.—The recently formed Association of Fellows of the Royal College of Surgeons in Ireland held a general meeting last week at the Gresham Hotel, Dublin. The increase in numbers since the foundation proves that the movement is finding support among the Fellows, whether resident in Ireland or elsewhere. The objects of the association are to further the welfare of the College, to induce the members to take an active part in the proceedings of the annual and other meetings, to approach the Council on all questions of material interest affecting the College, and to give the Council support in matters of professional interest. A council of 20 members was elected from among the members of the association, the first President selected being Lieutenant-Colonel F. G. Adye-Curran. The honorary secretaries are Mr. R. P. McDonnell (20, Lower Leeson-street, Dublin) and Mr. Andrew Charles (64, Harcourt-street, Dublin), and the honorary treasurer is Mr. C. J. Powell (30, Harcourt-street, Dublin). Letters expressing approval of the objects of the association were received from the President and various members of the Council of the College, and from many well-known Fellows in different parts of Great Britain and Ireland.

NEXT week's *Punch*, to be issued on May 18th, will be a Special King Edward Memorial Number, and will consist of 40 pages, chiefly of illustrations gathered from the pages of *Punch*, from the late King's birth in 1841 up to the date of his decease.

COLONIAL MEDICAL SERVICES.—*West African Medical Staff:* The death is announced of Mr. R. Welply, medical officer, Southern Nigeria. The following appointments have been made: Dr. G. de P. d'Amico (Gold Coast), Mr. G. F. Forde (Gold Coast), Dr. J. A. Harley (Gambia), Dr. A. Hutton (Northern Nigeria), Dr. J. Lindsay (Northern Nigeria), and Dr. R. C. Macpherson (Southern Nigeria). Dr. A. Hutton has been seconded in his appointment for a year to enable him to hold the post of demonstrator in the London School of Tropical Medicine. Mr. F. J. A. Baldwin has been transferred from the Gambia to Southern Nigeria.—*Other Colonies and Protectorates:* Dr. B. W. Cherrett has been appointed a medical officer in the East Africa Protectorate, Dr. E. P. Minett assistant Government bacteriologist in British Guiana, Mr. J. Pugh a medical officer in the East Africa Protectorate, and Mr. G. M. Sanderson a medical officer in the Nyasaland Protectorate.

THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, W.C.: POST-GRADUATE CLASSES.—Special courses of instruction (of three months' duration each) in the Surgical Diseases of Children will be held by members of the surgical staff four times a year. The classes will be held twice a week, on Tuesdays and Thursdays, at 5 P.M., and will comprise 24 meetings in each course. The fee for a single course is £5, but tickets for part of a course at reduced fees may be obtained by arrangement with the secretary. The classes will be held in the out-patient department or the museum, and will be illustrated by cases, specimens, skiagrams, and sketches at each meeting. The first course will begin on Tuesday, May 17th, at 5 P.M., and will be subdivided as follows: Diseases of Joints, May 17th to June 9th, Mr. George E. Waugh; General Surgical Diseases, June 14th to July 7th, Mr. O. L. Addison; Deformities, July 12th to August 4th, Mr. H. A. T. Fairbank.

THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.—At the last meeting of the Education Committee of the London County Council it was reported that a difficulty had arisen with regard to the offer of the medical practitioners of Norwood to treat 1500 children at a local centre. The committee accepted the offer, but declined to contribute a sum of £175 asked for in respect of the equipment of the premises. The Norwood committee then wrote that in the absence of an equipment grant the scheme could not be proceeded with. In the case of certain hospitals the Council had made grants for the purchase of equipment on the understanding that any apparatus so obtained should be the property of the Council. The Norwood committee was prepared to accept a grant on this condition, and the Education Committee accordingly sanctioned the expenditure. The arrangements made with the authorities of St. George's Hospital for the treatment of children suffering from ringworm having been found inadequate, the Education Committee accepted an offer by the governing body of St. Mary's Hospital, Paddington, to deal with 200 cases for one year upon payment by the Council of £100 a year and a capitation grant of 7*s*. Children suffering from eye, ear, nose, and throat affections are already being treated at St. Mary's Hospital. The committee recently asked the Board of Education to allow the attendances of children at hospitals to count as attendances at school for the purposes of grant earning. The Board of Education has replied that Article 44 of the Code was framed to meet cases where medical inspection could not be carried on within school premises, and in view of the difficulties the Board did not propose to amend the Code in the way suggested. The

Council in its application urged that the arrangements made for medical treatment of school children were in accord with the wishes of the Board, and to this the Board of Education replied that the Council was responsible for the particular method of providing medical treatment which had been sanctioned for London. The committee decided to ask the Highways Committee to permit parents and children going to the hospitals under the Council's scheme for medical treatment to travel on the tramcars at reduced fares. The County Council on May 10th approved the arrangements submitted for medical treatment in Wandsworth. No controversial business was taken at the sitting, the consideration of the report of the Asylums Committee with regard to the early treatment of the insane being postponed until after the Whitsuntide recess.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next general or quarterly meeting will be held at 11, Chandos-street, Cavendish-square, London, W., on Tuesday, May 24th, under the presidency of Professor W. Bevan-Lewis, at 3 o'clock.

MEDICAL GOLFING SOCIETY.—The 1910 tournament will be held on Thursday, June 2nd, at Burnham Beeches, by the kind invitation of the Burnham Beeches Golf Club. Anyone on the Medical or Dental Registers can join by payment of the annual subscription to the society, which is 5*s.*, and includes entrance to the tournament. Play will be as follows: 18 holes match play *v.* bogey under handicap. Class I. Handicaps 12 and under. Class II. Handicaps over 12. The "Henry Morris" Challenge Cup and the Medical Golfing Society's gold medal will be awarded for the best score under handicap. A first and second prize and a prize for the best last nine holes will be given in each class. (No player shall take a first or second prize *and* the prize for the best nine holes.) No previous play will be allowed on the day. Members of the Burnham Beeches Golf Club will deduct two from their handicaps. A foursome sweepstake will be arranged in the afternoon. Players must send entry with their annual subscriptions (5*s.*) on or before Monday, May 30th, to Mr. L. Eliot Creasy, honorary secretary and treasurer, Medical Golfing Society, 36, Weymouth-street, London, W. (Telephone 904 Paddington). Conveyances will meet the trains at Burnham Beeches station (G.W.R.).

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BRIMBLECOMBE, S. L., L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Medical Officer to the Wellington (Somerset) and District Cottage Hospital.

CAMPBELL, R. H., M.B., Ch.B. Glasg., has been appointed House Surgeon at the Hampstead General Hospital, with which is amalgamated the North-West London Hospital.

CHEATLE, ARTHUR H., F.R.C.S. Eng., has been appointed Lecturer in, and Teacher of Aural Surgery to, King's College Hospital.

DEWAR, T. F., M.D., C.M. Aberd., has been appointed a Medical Inspector for Scotland to the Local Government Board.

HANCOCK, DEBORAH, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Medical Inspector for the Gloucestershire Education Committee.

HARWOOD, T. E., M.B., Ch.B. Edin., has been appointed House Physician at the Hampstead General Hospital, with which is amalgamated the North-West London Hospital.

HERTZ, A. F., M.D., B.Ch. Oxon., M.R.C.P. Lond., has been appointed Physician for Nervous Diseases, with Charge of Out-patients, at Guy's Hospital.

HINCKS, THOMAS ERNEST, M.B., Ch.B. Edin., has been appointed District Medical Officer by the Hay (Brecon) Board of Guardians.

HINGSTON, CHARLES ALBERT, M.D. Lond., M.R.C.S., has been appointed Honorary Consulting Physician to the Crownhill Convalescent Home, near Plymouth.

JENKINS, G. J., M.S. Edin., F.R.C.S. Eng., has been appointed Assistant Aural Surgeon to King's College Hospital.

KINMOUTH, G. H., L.R.C.P. & S. Irel., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Lisdoonvarna District of the county of Clare.

LOUGHRIDGE, J. C., L.R.C.P. & S. Edin., L.F.P.S Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Carnmoney District of the county of Antrim.

LYND, J. C., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Limavady District of the county of Londonderry.

MARTIN, A. G., M.B., B.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Dungiven District of the county of Londonderry.

MOLLISON, W. M., M.C. Cantab., F.R.C.S. Eng., has been appointed Aural Surgeon to Guy's Hospital.

PIRIE, A. J., M.B., B.S. Aberd., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Ballindalloch District of the county of Banff.

PRANCE, GEOFFREY H., M.D., C.M. Edin., has been appointed Honorary Medical Officer to the Children's Convalescent Home, Weston-super-Mare.

PRITCHARD, URBAN, M.D. Edin., F.R.C.S. Eng., has been appointed Consulting Aural Surgeon to King's College Hospital.

ROSS, C. H. G., M.B., B.S.R.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Navan District of the county of Meath.

SCALES, JOHN EDWIN, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Kilmersdon District by the Frome (Somerset) Board of Guardians and for the Radstock District of the Clutton (Somerset) Union.

SOLTAU, ALFRED BERTRAM, M.D. Lond., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Physician to the Crownhill Convalescent Home, near Plymouth.

STEWART, MATTHEW J., M.B., Ch.B. Glasg., has been appointed Clinical Pathologist to the General Infirmary, Leeds.

THOMPSON, A. R., F.R.C.S. Eng., has been appointed Surgeon to the newly established Genito-urinary Department at Guy's Hospital.

WIGAN, CHARLES ARTHUR, M.D. Durh., M.R.C.S., L.S.A., has been elected Chairman of the Portishead (Somerset) District Council.

WILLIAMS, RICHARD, M.R.C.S., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Oculist for the County of Carnarvon by the Education Authority.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ALBERT DOCK HOSPITAL, Connaught-road, E.—Senior House Surgeon. Salary £75 per annum, with board, residence, and washing. Also House Surgeon. Salary £50 per annum, with board, residence, and washing.

ARMY MEDICAL SERVICE.—Ten Commissions in the Royal Army Medical Corps.

BANBURY, HORTON INFIRMARY.—House Surgeon. Salary £80 per annum, with board and residence.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon, unmarried. Salary £170 per annum, with rooms, &c. Also Resident Surgeon for from two to three months. Salary £4 4*s.* per week, with apartments.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—Honorary Medical Clinical Assistant. Also Honorary Surgical Clinical Assistant.

BRISTOL ROYAL INFIRMARY.—Honorary Medical Registrar.

BRITISH LYING-IN HOSPITAL, Endell-street, W.C.—Resident Medical Officer. Salary at rate of £50 per annum, with board, lodging, and washing.

BRIXTON DISPENSARY, Water-lane, S.W.—Resident Medical Officer, unmarried. Salary £150 per annum, with apartments, &c.

BURY INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, and laundry.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—House Surgeon, unmarried. Salary £80 a year, with board, lodging, and washing. Also Honorary Surgeon.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with rooms, board, washing, and attendance.

CROYDON GENERAL HOSPITAL.—Junior House Surgeon. Salary £60, with board, laundry, and residence.

DUDLEY, THE GUEST HOSPITAL.—Assistant House Surgeon for six months. Salary £75 per annum, with residence, board, attendance, and washing.

DUNDEE SCHOOL BOARD.—Chief Medical Officer. Salary £400 per annum.

FLEETWOOD, ROSSALL SCHOOL.—Resident Medical Officer, unmarried. Salary £250 per annum, with board and residence.

FOLKESTONE, VICTORIA HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with board, residence, and laundry.

HELLINGLY, EAST SUSSEX ASYLUM.—Locum Tenens Assistant Medical Officer for about four months. Salary 4 guineas a week, with board, lodging, and washing.

HEMEL HEMPSTEAD, WEST HERTS HOSPITAL. — House Surgeon. Salary £100 per annum, with rooms, board, and washing.

HOSPITAL FOR EPILEPSY AND PARALYSIS AND OTHER DISEASES OF THE NERVOUS SYSTEM, Maida Vale, W.—Resident Medical Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Assistant Casualty Medical Officer, unmarried, for six months. Salary £30, with board, residence, and washing. Also House Surgeon and House Physician, early in July.

JERSEY GENERAL DISPENSARY AND INFIRMARY.—Resident Medical Officer. Salary £100, with board and lodging.

KENDAL, WESTMORLAND CONSUMPTION SANATORIUM.—Assistant Resident Physician, unmarried. Salary £100 per annum, with residence, board, &c.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—House Surgeon for six months. Salary £50 per annum.

MANCHESTER CORPORATION.—Medical Officer (female) under the Midwives Act, 1902. Salary £250 per annum.

MANCHESTER, ST. MARY'S HOSPITALS FOR WOMEN AND CHILDREN.—House Surgeon. Salary at rate of £50 per annum, with board and residence.

MILLER GENERAL HOSPITAL FOR SOUTH-EAST LONDON, Greenwich-road, S.E.—Honorary Physician.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—House Physician at Northwood. Salary £75 per annum, with board, residence, and washing.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Albany Memorial), Queen-square, Bloomsbury.—Senior House Physician. Salary £50 per annum, with board and residence.

NEW HOSPITAL FOR WOMEN.—Assistant Surgeon, House Physician and Resident Medical Officer, and Clinical Assistant (all females).

NOTTINGHAM GENERAL HOSPITAL.—Locum Tenens. Salary £45, with board, lodging, and washing.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Also House Physician. Salary £75 per annum, with board, residence, and washing.

PRESTWICH, COUNTY ASYLUM, Manchester.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, and washing. Also Locum Tenens, unmarried, for six to eight weeks. Salary 4 guineas per week, with apartments, board, &c.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Two House Surgeons and House Physician, each for six months. Salary £60 per annum, with board, residence, and washing.

REDHILL, EARLSWOOD ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £130 per annum, with board, lodging, and washing.

ROYAL EAR HOSPITAL, Soho.—Honorary Assistant Anæsthetist.

ROYAL EYE HOSPITAL, Southwark, S.E.—Honorary Assistant Surgeon.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Ventnor.—Two Assistant Resident Medical Officers, unmarried. Salary £100 per annum each, with board, lodging, and washing.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—Surgeon.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand, W.C.—Clinical Assistants for six months.

SALISBURY, FISHERTON HOUSE ASYLUM.—Assistant Medical Officer unmarried. Salary £150 per annum, with board, washing, lodging, &c.

SCARBOROUGH HOSPITAL AND DISPENSARY.—Junior House Surgeon for six months. Salary £80 per annum, with board, residence, and laundry.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.

SOUTH SHIELDS, INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Senior House Surgeon. Salary £100 per annum, with residence, board, and washing.

STAMFORD, RUTLAND, AND GENERAL INFIRMARY AND FEVER HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

STOCKPORT INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, washing, and residence.

SWANSEA GENERAL AND EYE HOSPITAL.—House Physician. Salary £75 per annum, with board, washing, and attendance.

TAUNTON, TAUNTON AND SOMERSET HOSPITAL.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry.

UNIVERSITY OF LONDON: UNIVERSITY COLLEGE.—Assistant in Anatomy and Curator of the Anatomical Museum.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Surgeon for six months. Salary £30, with board, lodging, and laundry.

WAKEFIELD, COUNTY COUNCIL OF THE WEST RIDING OF YORKSHIRE.—Lady Medical Inspector. Salary £300 per annum.

WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM PARALYSIS, AND EPILEPSY, 73, Welbeck-street, W.—Out-patients' Physician.

WEST LONDON HOSPITAL, Hammersmith-road, W.—House Physician for six months. Board, lodging, and laundry allowance provided.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon. Salary £80 per annum, with board, rooms, and laundry.

Births, Marriages, and Deaths.

BIRTHS.

NOEL-COX.—On May 7th, at Elcove, Eastbourne, the wife of Herbert Lovis Noel-Cox, M.D., F.R.A.S., of a daughter.

WEBSTER.—On April 28th, at the Barracks, Shoeburyness, the wife of Captain J. A. W. Webster, R.A.M.C., of a son.

MARRIAGES.

ELLIOT—STANLEY-SMITH.—On May 6th, at Vancouver, British Columbia, Frederick H. T. Elliot, son of Lieutenant-Colonel A. F. Elliot, late Royal Army Medical Corps, of Exmouth, to Mary Doris Stanley, daughter of E. Stanley-Smith, M.D., of 68, Wimpole-street, W.

HOMAN—LONGFIELD.—On April 27th, at St. James's Church, Mallow, Thomas Delapere Homan, M.D., to Elizabeth Frances Rose, daughter of the late Henry Longfield, of Broadview, Mallow.

DEATHS.

CAMERON.—On May 7th, at Aldershot, Kenneth Mackenzie Cameron, Major, R.A.M.C., of tetanus, resulting from an accident, aged 41 years.

HITCHINS.—On May 8th, at Trevarrick, St. Austell, Cornwall, Frederick Charles Hitchins, M.R.C.S., L.R.C.P., F.R.C.S. Edin., aged 38 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

CLIMATE AND PUBLIC HEALTH IN BRITISH EAST AFRICA.

Sir E. P. C. Girouard, K.C.M.G., D.S.O., Governor of the East Africa Protectorate, has forwarded to the Colonial Office his annual report for 1908-09, in the course of which it is stated that the population of the Protectorate is roughly estimated at 4,000,000, including about 2000 whites. The Births and Deaths Registration Ordinance renders compulsory the registration of the deaths of Europeans, Americans, and Indians throughout the Protectorate, and of all deaths, including natives, in township areas. The registration of births among natives is not, however, required, and the number of deaths is only a small proportion of those which occur. It would be obviously impossible to register all native deaths, and the figures given cannot be looked on as accurate or in any way a test of the growth or decline of the population. The returns of births (European, American, and Indian) for 1908-09 numbered 172, whilst those of deaths (including natives in townships only) totalled 1588. The year could not be considered as a favourable one as far as the public health was concerned, and the death-rate largely increased. As regards the health of Europeans generally, the number of admissions to hospital was considerably more than in 1907-08, and there were probably many unrecorded cases occurring on outlying farms beyond the reach of medical aid. Nervous diseases play a prominent part, and, situated as the Protectorate is practically on the Equator, and as far as the bulk of the population is concerned at a considerable altitude, it is, to say the least, open to question whether East Africa can ever become what is known as a White Man's Country. The climate is an ideal one for travellers and sportsmen, provided that they avoid certain districts, and there are few parts of the world where a holiday can be more enjoyably spent; but the general medical opinion is that continuous residence on the high plateau has a cumulative effect on the nervous system, often culminating in a complete breakdown in cases where there has been overwork or mental anxiety. Settlers and merchants find it necessary to pay periodical visits to Europe, and suffer in health when unable to do so. Twenty-three cases of enteric fever occurred with only one death, of which 14 were among Europeans, and it can safely be predicted that this disease will spread. Its existence points to the unsatisfactory condition of the sanitation and water-supply in certain localities. In view of the widespread existence of sleeping sickness in Kavirondo, it was decided to remove the natives from the lake shores, but they showed great reluctance to leave their villages near the lake, and especially their fishing, which is not only the chief source of their food-supply but also their amusement. It is also one of the most dangerous sources of infection. The scheme had to be temporarily abandoned owing to the unfortunate death of Dr. Baker, and it is greatly to be feared that moral suasion by itself will effect but little in this direction. There was an outbreak of plague, lasting over four months, at Kisumu, where, unfortunately, the disease appears to be endemic. There were 79 cases, 59 of which proved fatal, a death-rate of 74·68 per cent., considerably less than that during the last outbreak; this may be attributed to the prompt evacuation of infected villages and the use of Haffkine's serum. The number of blackwater fever cases has increased slightly amongst Indians and Goanese, but hitherto there has been no instance of an African native developing this disease. Malaria is responsible for a considerably larger number of cases and deaths than in previous years, and the deaths from tuberculosis have more than doubled. There were a few cases of beri-beri in the gaol at Nairobi, due, probably, to the unsuitability of the building, which will shortly be superseded by a new and up-to-date prison. Only two cases of leprosy came for treatment, but there is no doubt that this disease is very much more widely spread than is known, especially in the coast districts. Measures are being taken to enable the Government to exercise a stricter control than has hitherto been possible in this respect. There is a leper settlement at Mkonumbi, near Lamu. The cases treated for syphilis were less in number, but this forms no criterion of the extent of the disease, which it is to be feared is very prevalent. The number of admissions for rheumatism was considerably less than in 1907-08, the chief reason being probably the dry season. There is an increase in the number of cases of diseases of the eye and ear and of the respiratory system. Diseases of the digestive system, though forming a considerable item in the total number of cases treated, remained much the same as in the previous year. No striking developments or improvements in the sanitary conditions of the Protectorate can be chronicled, but there has been steady progress along the lines of municipal improvement already laid down. The lack of an adequate water-supply must be emphasised as a bar to efficient sanitation, and this applies especially to the four principal towns—Mombasa, Nairobi, Nakuru, and Kisumu. Much good work has been done everywhere in clearing bush and rank

vegetation, and drainage has made satisfactory progress. There are European Government hospitals at Mombasa and Nairobi. The former, one of the oldest buildings in the Protectorate, underwent some much-needed repairs, but it is questionable whether it will fulfil much longer the purpose for which it was intended. The new Nairobi hospital was opened during the year; it is a spacious and well-fitted building, and should provide ample accommodation for the needs of the town for many years to come. There are 30 native hospitals and dispensaries in the Protectorate, but the majority of these are quite unsuitable, not having been erected in the first instance for the purpose for which they are now used.

THE STERILISATION OF WATER BY MEANS OF ULTRA-VIOLET RAYS.

THE sterilisation of water by ultra-violet rays has passed from the region of experiment to that of actual practice. In an annotation in THE LANCET of April 2nd it was reported that work on a very large scale had lately been done in France, and that a complete system of sterilisation had been established for alimentary purposes, the sole agent employed being the ultra-violet rays created in the Cooper Hewitt lamp made from transparent quartz. We have since received from the Westinghouse Cooper Hewitt Company, Limited, of 151–152, Great Saffron-hill, Charterhouse-street, London, E.C., a copy of their list in which is described the Westinghouse water steriliser. This apparatus evidently represents the latest developments in this connexion and provides a constant supply of absolutely sterile water, should such be required, without imparting any taste to, or removing natural gases or salts from, the solution. Bactericidal action is due entirely to the ultra-violet rays, which are produced by a transparent quartz lamp of the "Westinghouse Silica" type suspended above and close to the surface of the liquid. Apparently the action is not due to the intermediary formation of ozone or peroxide of hydrogen. The ultra-violet rays being absorbed by opaque bodies the apparatus must be fed with clear water such as is generally delivered by a town supply. In any case matter in suspension in a water intended for drinking purposes is always objectionable and it is easily removed. The Westinghouse steriliser will deliver up to 132 gallons per hour of completely sterilised water. Apart from its application to many domestic and hygienic questions, there is clearly an important field for its employment in surgery and medicine. There is no difficulty in attaching the apparatus to the water service and the electric lamp operates on a direct current of 100–130 volts, the consumption being 3·5 ampères.

THE DANGERS OF CANNED FRUIT.

A HIGHLY important report was presented to the West Sussex county council by its public analyst, Mr. Otto Hehner, at the meeting on May 6th. In these days it would be thought that there could be no need to emphasise the evils and dangers that must arise from the consumption of impure and unsound food; but it is probably through the ignorance of the consumer as to what he is eating that there is such a large consumption of foodstuffs which may prove, and undoubtedly do in very many cases, very injurious to health. Mr. Hehner in his report draws attention to the dangers of eating tinned fruits canned as they are at the present time. "On opening a tin containing preserved tomatoes," Mr. Hehner says, "or any other acid fruit, it can in every case be easily observed that the tin surface shows marks of etching. The acid while in contact with the tin gradually attacks and dissolves it. As a consequence the tin gradually leaves the canister and permeates the fruit. The more acid and the older the goods the greater is the proportion of tin which contaminates the food, until a time is reached when the acid perforates the canister. Tin compounds are by no means without physiological action, and when ingested in quantities beyond 2 or 3 grains per day gradually accumulate in the body and then become injurious." Mr. Hehner goes on to refer to his analysis of seven samples of tomatoes, and expresses his opinion that those containing 3·2, 3·6, 5·0, 5·5, 6·5, and 6·8 grains of tin per pound were unfit for food. The figures refer to six of the seven samples, the remaining one, containing 2·7 grains of tin per pound, Mr. Hehner possibly thinks might not be injurious. And Mr. Hehner points out that his remarks not only apply to tomatoes but to pineapples, pears, peaches, and apples. These tinned fruit are eaten by the unwary in large quantities without obvious injurious effects, but if the consumer knew that what he does consume is fruit plus tin, he would, if he valued his health, object to this sort of delicacy. "In my opinion," Mr. Hehner says, "which is based upon the experience of very many years, I consider the preservation of acid fruits in tin canisters to be entirely improper and fraught with danger to the health of the community unless the 'canner' takes some means to protect the inner surface of the canister, by application of varnish or lacquer, from the attack of the acid. The trade in canned goods has assumed such gigantic proportions, and has been allowed to go unchecked for so many years, that it is impossible for an individual public officer like myself to stem the tide. I, nevertheless, take this, the first opportunity which I have had in my public capacity, to raise my voice of warning against the consumption of food of this kind, which from the very manner of its preservation is bound to be impregnated with a metal that should have no place in the human body." Mr. Hehner concludes his report by complaining of the absence of the necessary power to bring the persons who thus debase and defile food to justice, and wonders that the inhabitants of the country do not insist that the Government furnished its officers with that power.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.

WEDNESDAY.—8 P.M., Mr. E. Heron-Allen and Mr. A. Earland: On the Recent and Fossil Foraminifera of the Shore Sands of Selsey Bill:—V., The Cretaceous Foraminifera.—Mr. E. M. Nelson: On the Resolution of New Detail in Coccinodiscus Asteromphalus.—Dr. M. D. Ewell: Comparative Micrometric Measurements. Mr. E. Heron-Allen and Mr. A. Earland: Exhibition of Living Foraminifera from Selsey.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

TUESDAY.—4 P.M., Dr. E. Wynter: Clinique (Medical). 5.15 P.M., Lecture:—Dr. G. C. Cathcart: How to Treat Sore Throat.

WEDNESDAY.—4 P.M., Mr. T. P. Legg: Clinique (Surgical). 5.15 P.M. Lecture:—Dr. L. H. Pegler: Headaches in Relation to Obstructions in the Nasal Passages.

THURSDAY.—4 P.M., Sir Jonathan Hutchinson: Museum Demonstration. 5.15 P.M., Lecture:—Mr. P. L. Mummery: The Treatment of Internal Piles.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 10.30 A.M., Demonstrations in Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Operations of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. S. Taylor: Typhoid.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Morton: X Ray Examination of the Digestive System (illustrated).

THURSDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Armour: Operations for Hernia.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. Medical Registrar: Demonstration of Cases. 2 P.M., Dr. Davis: Diseases of the Throat, Nose, and Ear. X Rays. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Abraham: Cases of Skin Diseases.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 3.30 P.M., Special Lecture:—Mr. Cargill: Sympathetic Ophthalmitis.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4 P.M., Special Lecture:—Dr. Lister: Infantile Feeding.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. Howell Evans). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson).

TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G Auld). 2.30 P.M., Operations. Clinics:—Surgical (Mr. W. Edmunds); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Dr. R. M. Leslie: Irregularity of the Heart, its Causes and Significance.

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie).
THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., Lecture:—Mr. W. Edmunds: Surgical Tuberculosis.
FRIDAY.—10 A.M., Clinic:—Surgical Out-patient (Mr. Howell Evans). 2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Mr. Godlee: Foreign Bodies in the Air Passages.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Mr. W. Wallis: Mouth and Teeth.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. J. Collier.

HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON), Great Ormond-street, W.C.

THURSDAY.—4 P.M., Lecture:—Dr. Batten: Influenzal Meningitis.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.),

TUESDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

WEDNESDAY (18th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (19th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (21st).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)
